INDEX OF CONTENTS.

JANUARY TO JUNE, 1897.

(Issued with the Number for July 3, 1897.)

A

ABERNETHY University, proposed botanical garden for, 26; agricultural education in, 62
 Abies arizonica, 35; A. bracteata, 291, 341; measurements of, at Tortworth, 305; A. Meuziesii, 341
 Achimenes of the Victorian Era, 423
 Adiantum capillus veneris var. semi-lanatum, 112; A. cucullatum, 193
 Adonis amurensis, 153
 Adonis vernalis, 194
 Agaric, a parasitic, 284
 Agathis obtusa in New Hebrides, 300
 Agaves, polycarpic, 166
 Agricultural estates, revenue from, 361, 386
 Album, an old, of floral drawings, 114
 Allotment gardens at High Wycombe, 308
 Alpine garden, a new, on Little St. Bernard, 419
 Alpine plants on walls, the cultivation of, 184
 Alpines, the cultivation of tender, 168
 Alternations of generations, 289, 374
 Amasoria pumica, 153
 Amelanchier caudensis var. oblongifolia, 333
 Amelanchier, the species of, 265
 American forest reserves, 179; the state of, 204
 American fruit in Vienna, 62
 American notes, 3, 73, 86, 179, 278, 311
 American Palms, 90; trees, 101
 Ammonium sulphate, a cheap manure, 217
 Auenoae, a new double white, 381; blanda vera, 2; A. fulgens, the Riviera and Greek forms of, 279
 Auburium Scherzerianum, varieties of, from Shipley Hall, 353
 Antiques, experimental farm, 333
 Antirrhinum, 252
 Ants in houses, the destruction of, 224; how to drive away, 303
 Apiary, the, 75, 107, 133, 171, 203, 219, 235, 287, 335, 367, 401, 419
 Apparatus, a germinating, 143
 Apple-blossom weevil, 289
 Apple, Bramley's Seedling, 240, 259, 277, 290, 324; classification and the Royal Horticultural Society, 128; crop in America, 171; culture, and cyder-making, 206; Pear tree and, 206; shipments from America, 3; the Spice, 128; Yorkshire Greening, 240
 Apples, a perfect cluster of, 26, 65, 97; Bramley's Seedling and Lane's Prince Albert, 348; favour in, 27; from Tasmania, 274; from the Antipodes, 169, 258, 290; petals, 341; the classification of, 144
 Apricots under glass at Arncliffe, 373; in Scotland, 369
 Aquilegia, 252, 311, 347; of the Victorian Era, 423
 Arancaria lubricata uplifted at South Lychett, 288
 Arbor-Day, 246, 345; its advantages, 175; at Eynsford, Kent, 158
 Architecture, gardening and, 117, 124
 Arecia Catechu, 243

Aristolochia Goldieana, 337; A. Westlandii, 276
 Arncliffe, Apricots at, 373
 Arthropylum medium, 194
 Arum Dioscoridis spectabile, 2
 Arundel Castle Gardens, winter-flowering plants at, 57
 Asclepias curassavica, 217
 Ashford, Wilmslow, Orchids at, 298
 Asparagus, the forcing of, 201; tinned, 239; A. plumosus, 260
 Assessments to local rates, farmers', 126
 Asters, Stocks, and Zinnias, 216
 Atoll of Fouafuti, the, 345
 Auricula, double white, 341
 Auriculas, 98; of the Victorian Era, 423
 Australia, Western, vegetation of, 33
 Azalea indica, 330
 Azaleus of the Victorian Era, 423

B

BARLEY as a base for port-wine, 289
 Barley emuls, 242
 Basic slag as a garden manure, 266
 Bay Laurel, the, 162
 Beches, a Monograph of, 305
 Beet, Chilian, as a winter decorative plant, 28
 Beetroots, 259
 Begonias of the Victorian Era, 424
 Belgium, notes from, 386
 Bellavilla Heldreichi var., 2
 Belvoir Castle, spring gardening at, 329
 Benevolent Institution, Gardeners' Royal, 25, 42, 45, 109, 144, 205, 220; annual dinner of the, 359; Worcester branch of the, 256
 Berberis stenophylla x, 302
 Berlin and Hamburg shows, the, 304, 310
 Berlin, notes from, 192
 Bibliography of the Dahlia, the, 329
 Birch branch, with Pityopsis, 341
 Birds and Chimonanthus, 324
 Bolbophyllum piloglossum, 330

BOOKS, NOTICES OF.—A Directory of Titled Persons for the Year 1897, 159; A Great Agricultural Estate (Duke of Bedford), 361, 386; Aide-Memoire de Botanique Cryptogamique (Hort. Brown), 297; Round the Year: a series of short Nature Studies (Prof. L. C. Miall), 12; Sweet Peas up to late (Burpee), 141; The Dahlia (M. Cuthbertson), 221; The Forcing-Book (L. H. Bailey), 322; The Journal of Essex Technical Laboratories, 309; The New Gulliver: or Travels in Athosia (C. T. Drury), 9; The Romanian's Year-Book, 44; The Silva of N. America, vol. x, (Sargent), 9, 101; The Survival of the Unlike (L. H. Bailey), 69, 85, 133; The Wasted Orchards of England, 237; War, Famine, and our Food Supply (R. B. Merton), 258

Botanical explorations sixty years ago, 274
 Botanical institute, a suggested, 190
 Botanical Society, a for Western Australia, 403
 Botanical survey of the Cour d'Alène Mountains in Idaho, 215
 Botany, economic, and its applications, 92
 Bouquet the feather-weight, 290; the Royal Jubilee, 420
 Braeken, how to disestablish, 306, 349; transplugging, 260, 277, 290
 Breeding backwards, 313
 British Guano, 50
 British woodland, types of, 181, 260, 295, 361
 Broccoli, late, 374, 109, 418
 Brusas, Cyripediusus, 17
 Bryaston, Blandford, notes from, 161
 Buckingham Palace and gardens, 326
 Bud transference and its effects on fruit, 211
 Bud variation in Pyrus japonica, 318
 Budding the Lemon, 26
 Bulb, hardy, culture in England, 211
 Bulbophyllum barbigerrum, 194; B. coniosum, 85; B. Eriassoni, 61
 Bulbs from Central, 112; in the London parks, 235; modern treatment of spring-flowering, 308, 324, 341, 350, 373, 389
 Bulbs with arrested roots, 211

C

CATNO flower shows, 127, 370
 Caladium, 165
 Calceula cilicaris, 88
 Calceolarias at Arundel Castle, 57
 Calceolarias of the Victorian Era, 124
 Calcutta Botanic Gardens, 61
 Camellias of the Victorian Era 421
 Candlen Wood, Orchids at, 232
 Caudex, 294
 Camellia at Glen Eyre, 219
 Campanula Balcanica, 121
 Canna, the cultivation of the, 110
 Cans, Crozy and his, 302; in America, 7; in water, cultivation of, 192
 Cape fruit, 68
 Cape Town Municipal Gardens, succulents in, 122

- Capture-plants for insect pests, 346
 Cardoon, the, as a decorative plant, 191
 Carnation leaves diseased, 241
 Carnations and Picotees, 129; on the Continent, 40
 Carnations, Marguerite, 27
 Carnations at Osberton, 10
 Cape, fruit from the, 275
 Carpet bedding, 357
 Carrot-fly, the, 288
 Carrot-seed sent to India, 368
 Castleroy, Broughty Ferry, 315
 Catalpa bignonioides, 341; *C. syriaca*, 298
 Catasatum semiprostratum, 54
 Cattleya maxima gigantea, 22; *C. Percivaliana*, 159; *C. Schroderae*, 330; *C. superba*, 416; *C. Trianae*, 165; *C. Warneri*, 198
 Cecropia palmata, 409
 Cedars of Lebanon, the, 145; and seminal variations, 162
 Cedrus Deodara, 11, 50, 82, 97, 113; and *C. atlantica*, 65
 Cedrus Deodara as a forest-tree, 54; for north, 129; *C. Libani*, 113
 Celery-growing in America, 72
 Centrosoma Plumieri and pubescens, 169
 Centhalotaxa pedunculata fastigiata, 285
 Cereal crops in Great Britain, 26
 Champs Elysées, Paris, the trees in the, 165
 Chaucery in winter, 250
 Chilian Beet as a winter decorative-plant for the conservatory, 28
 Chimionanthus attacked by birds, 324
 Chionodoxa × Albeii, 159, 191, 207
 Chivwick, the garden at, 6, 128, 321
 Chitral, bulbs from, 112
 Christmas Roses, the, 18; trade in fruit, 11
 Chrysanthemum, a, as grown in Japan, 254
 Chrysanthemum literature, recent, 149
 Chrysanthemum nipponicum, 46; *C. Princess Victoria*, 38; sport, 129; trade, the, 104; when to propagate the, 32, 98; late, 28; miniature, 199; notes on, 38
 Cineraria Bonai de Neige, 274; *C. cruenta*, 66; 279
 Cineraria hybrida, 46, 81, 63, 310
 Cinerarias, 309; of the Victorian Era, 424
 Ciriopetalum Medusae, 25
 Citrus tribe in Sicily, products of the, 283
 Claremont, the gardens at, 413
 Clarke, the late Colonel, 277
 Classification of fruits in competition, the, 150
 Cliveden, spring gardening at, 284
 Clock Garden, a, 370
 Clozone Orchid-pot, the, 80
 Cocciellidae, and Scale-insects, 306
 Cockroaches, 340; in Grenada, 20
 Colicemus (Crotons), the culture of, 111
 Cologne cristata, 173
 Coffee, the cultivation of, and preparation for market, 12
 Colechicum Börnuellieri, 2; *C. candidum*, 2; *C. ciliatum*, 2; *C. Ritchiei*, 2
 Colons, the cultivation of, 99, 168
 Colonial Notes, 29, 163, 248, 300, 333, 409
 Colourists' neglect of native plants, 88
 Colouring Narcissus flowers, 66
 Commissions, secret trade, 220
 Coniferous woods, 130
 Conifers, from seed, 314; the mineral food of, 209
 Conservatories, the furnishing of, 214
 Coombe House, Croydon, spring flowers at, 236
 Copelands, Orchid Exhibition at, 206
 Corn-plant in the construction of war vessels, 289
 Corn products, a new, 289
 Correas, the culture of, 216
 Corydalis rufefolia, 2
 Cottons, Indian, 256
 Couch grass, how to clear from land, 28
 Covent Garden Market, a new toll at, 50
 Cowdorp Oak, the, 338
 Crataegus, the species of, 87, 102, 119, 135
 Crete and its products, 220
 Crozy and his Camas, 362
 Cupressus macrocarpa, 66, 83
 Currants, the Greek, 237
 Cycas revoluta, a new use for, 273
 Cyclamen, a gigantic, 206
 Cyclamen latifolium, exhibited by Vilmoren, Andreux et Cie., 338
 Cyclamen persicum = latifolium, a new strain of, 81
 Cyclamen, the, and its culture, 27; the future of the, 80; the (so-called) Persian, 24; progress of the, 316, 330, 350, 372
 Cyclamens at Nostell Priory, 28; failing to open their flowers, 11, 81; modified flowers of, 71; seedling, 162
 Cycnoches Lodgesii, 194
 Cyder and Perry-fruits, 173
 Cybidium tigrinum, 198
 Cypripedium, a dimorphic, 62; *C. bellatulum*, as grown at Ribblesdale, 321; *C. callosum* Sandera, 70; *C. Gratiarivum*, 199; *C. insigne* Sandera, 70, 96, 128, 145, 162; *C. insigne*, a spotted variety of, 102; *C. Lawrenceanum* Hyeaun, 36; *C. Lawrenceanum* with a developed stem, 290; *C. × Lilian* Greenwood, 35; *C. Nansen*, 246
 Cypripedium in Brussels, 48
 Cypripedium punctatum, 232
 Cytisus albus, 392; *C. Ardoini*, 302; *C. precox* ×, history of, 301, 340
- D**
- DARFODIL with filled corona, 270
 Daffodils at Spalding, 295; in pots, the cultivation of, 105, 153; synanthic, 279
 Dahlia, the bibliography of the, 329
 Daphne Blagayana, 251; *D. laureola*, 216; *D. Mezereum*, 216, 291; *D. M. album*, a fine specimen of, 183; *D. pontica*, 324
 Darwin Tulips, 341, 372
 Decorations, rural, 4
 Dendrobium Amboinense, 266; *D. Dalhousiana*, 156; *D. Falconeri*, a fine, 350; *D. Johannis*, 102; *D. Kenneth*, 134; *D. noble*, a well-flowered, 183; *D. n.*, a case of abnormal flowering in, 56; *D. n. var. Cooksoni*, 224; *D. n. nobiliss*, 165, 198; *D. papilio*, 416; *D. × rubens* grandiflorum, 293; *D. × Schneiberianum*, 182; *D. transparens* album, 198; *D. Victoria Regina*, 399; *D. Wardianum* candidum, 134
 Deodar Cedar, the, 97
 Deptford, a new park for, 403
 Dimorphic Cypripedium, 62
 Disa Harviana and *D. lugens*, 1801; *D. sagittalis*, 283
 Diseases of plants, 245; of the Narcissus, 233
 Douglas Fir, the, and its synonyms, 206
 Douglas, Mr. Jas., presentation to, 257
 Draconia Linden, 358
 Drawings, an old album of floral, 115
 Drift-wood from Arctic seas, 194
 Drumlrig, retirement of Mr. D. Thomson from, 94
 Dunes, the New Jersey, the planting of the American Holly upon the, 94
 Dunn's turf cutter, 323
- E**
- EARL'S COURT Exhibition, the gardens at, 386
 Earthaunts, 279
 Echites synphytoearpa, 243
 Edinburgh Botanic Garden, notes from the, 101, 191, 225, 276, 325
 Edinburgh, the Grapes at, 128
 Education, technical, 369
 Eel-worms in pastures, 323, 340, 350
 Effects in exhibition, 63
 Electric light for forcing-houses, 274

1897

THE
Gardeners' Chronicle.

SATURDAY, JANUARY 2, 1897.

NOVELTIES OF 1896.

A REVIEW of the subjects brought into cultivation during the year 1896, either by the efforts of the importer or by the skill of the hybridist, discloses the fact that the industry of the gardener in the matter of home-raised hybrids, in the showier genera to which he invariably fixes his attention, has been by far the most successful, and in spite of the evidence that careless or unhappy cross-fertilisation has brought, especially in *Cypripedium*, many kinds which may well be denominated "weeds," the number of beautiful novelties obtained will more than compensate for their presence until they gradually disappear after the manner of most plants unworthy of cultivation.

THE ORCHIDS

may be taken first, and among them we find that no importation in quantity of any species worthy to rank with the favourite *Dendrobium Phalaenopsis* Schroderianum, or with the first importation in quantity of the favourite *Cattleya labiata* autumnalis, has been made, and the main interest in this class centres in the pretty, or botanical species, which have come either as isolated plants, or in the small quantities which such rare gems usually arrive.

To glance first at the chief things which have flowed for the first time, or been exhibited and received awards from amateur's collections, we find that—

Baron Sir H. SCHRODER, whose grand collection of priceless varieties of *Odontoglossum crispum* increases in vigour every year, and plainly answers the oft-mooted question, "Do *Odontoglossums*, and many other Orchids, inevitably decline under cultivation?" Those who watch the successive appearances of the unique varieties of *O. crispum* from "The Dell," note the increasing vigour and size and beauty of flower, of which *O. c. nobiliss*, which when first shown was considered beautiful enough, but which in its second appearance totally eclipsed its former effort, a feat which was again excelled when it took a Silver Medal at the Royal Horticultural Society on February 11, 1896. So also with *Cattleya* × *Hardyana splendens*, and *Vanda tores gigantea*, both of which probably rather from good culture than from any extraordinary quality in themselves,

so far surpassed those previously seen as to secure First-class Certificates. *Odontoglossum crispum* *Eveline*, shown from The Dell, is a grand form, with fine dark purple markings; *Dendrobium thyrsiflorum* *Lowianum*, a remarkable variety, with a totally different labellum to the type; and early in the year the pretty *Vanda* × *Charlesworthii* was first shown from The Dell.

Sir TREVOR LAWRENCE, Bart., President of the Royal Horticultural Society, possesses a wonderful collection, in which doubtless many a pretty and rare species flowers without the event being recorded. At the last meeting of Royal Horticultural Society, in the showy group of Harford hybrid *Calanthes*, some few new forms appeared, which have yet to develop; and at previous meetings the handsome *Cattleya Trianae* *Reine des Belges*, the fine *Cymbidium* × *Lowio-eburneum*, the showy *Dendrobium* × *Chio*, *D.* × *pallens*, *D.* × *speciosum* *Kingianum*, and *D.* × *Wiganie* have been Certificated, the last-named, which was first shown by Sir Frederick Wigan, being also exhibited by Messrs. Veitch, all three exhibitors making the cross (*nobile* × *signatum*) independently of each other. Sir Trevor Lawrence also showed for the first time the distinct-looking *Odontoglossum aspidorrhinum*, and succeeded in getting recognised the rare *Dendrobium cymbidioides*, *Zygopetalum grandiflorum*, *Platytelis uncaata*, *Bulbophyllum auricomum*, *Cirrhopetalum nutans*, and many other species which, like those mentioned, are well known to science, but seldom seen in gardens.

The Hon. WALTER ROTHSCHILD, a great authority in other branches of natural history, continues to pursue with increasing interest the scientific side of Orchid culture, and his large and curious collection has during the year produced many remarkable and undoubted new species. Of them, *Stanhopea im. ressa*, Rolfe, had a totally new feature in its showy flowers, viz., a deep irregular indentation in the under-side of the lip; and *S. Wardi* *superba*, as a variety, is far in advance of any of its section in point of beauty. *Choodrohycha albicans*, Rolfe, is a very interesting species, seemingly containing *Stenia* and *Chondrohycha*: *Mormoles badium*, a very showy new species; and the wonderful *Bulbophyllum* *Eriessoni*, which fully bears out Dr. Kranzlin's description, and of which we hope to give an illustration from the spike kindly sent by Mr. Rothschild. Both these fine plants were imported by Messrs. F. Sander & Co., and only one of each has flowered, which are now incorporated in the Tring Park collection. Other plants for which the Hon. Walter Rothschild has received Certificates at the Royal Horticultural Society during the past year are *Catasetum* × *splendens* *leucanthum*, *Cynoches maculatum*, *Honoleta tigrina*, of which probably H. Lansberg and H.

Lowiana are at best only varieties; several new, but un-determined, *Cirrhopetalums* and *Bulbophyllums*; and of rare species, not exhibited, the handsome *Diss pilchra*, *Ansellia confusa*, *Catasetum uncaatum*, and other *Catasetums*, &c. (referred to in last week's *Gardeners' Chronicle*).

NORMAN C. COOKSON, Esq., from his famed collection of home-raised hybrid Orchids at Wylam, Newcastle, has exhibited and received awards for several remarkable and showy Orchids, which are a distinct gain to gardens. Of these, *Odontoglossum* × *Halli-crispum* deserves special mention, as much for its great beauty as for its general interest, on account of *Odontoglossums* being difficult to raise and perfect. Of *Dendrobium*, Mr. Cookson's *D.* × *Dulca* "Oakwood variety" and *D.* × *Dulce picturatum* are two bright flowers, the latter curiously striped and flaked; *D.* × *Murrayi* (*albo-sanguineum* × *nobile*); and *D.* × *Kenneth* (*Bensonie* × *McCartinae*), two remarkable crosses, the former for beauty and chaste tinting being by far the better; *D.* × *Doris* and *D.* × *Cassiope virginale*, are two very pretty white kinds with maroon spot on the lip; and *Lelio-Cattleya* × *Doris* (*harpophylla* × *Trianae*); *L. C.* × *Bryan* (*C. Gaskelliana* × *L. crispata*) and *L. C.* × *Clivia* (*pumila prasians* × *Dawsoniana*), all previously noted, received Certificates in 1896.

To Mr. Cookson's labours also are due the verification of the record of *Cattleya* × *Hardyana* by home-raised seedlings; and the still more interesting fact that what are called "albino" come true from seeds, he having flowered *Cypripedium* *Lawrenceanum* *Hyanum*, raised, and apparently improved, and who has kindly forwarded a flower, which we hope to illustrate. In the same way the kindred *albino*, *C. callousum* *Sanderæ*, is also producing flowers true to their variety with Mr. Cookson.

The Right Hon. JOSEPH CHAMBERLAIN during the year gives as the first-fruits of his efforts in raising hybrid Orchids, the pretty *Masdevalla* × *Shuttryana*, Chamberlain's variety, distinct enough from the original to warrant an independent name were it not for the "exigencies" which affect florists as well as politicians. In this case the original name for the recorded parentage had to be observed. Two other very pretty hybrids from Highbury are *Lelio-Cattleya* × *Highburyana* (*C. Lawrenceana* × *L. enobarbata*) and *Dendrobium* × *Andromeda* (*Cassiope* × *Leechiana*).

EDGAR ASHWORTH, Esq., of Harefield Hall, Wiltshire, one of the most liberal of Orchid patrons, has assimilated into his collection some of the best plants of the past season, among which are the lovely albino *Lelia pumila* *alba* "E. Ashworth" (see fig. 3, p. 11), for which he received a First-class Certificate at the last Royal Horticultural Society's meeting of the year. Other first-class novelties of this collection are the nearly pure white *Lelia purpurata* *Lowii* (first shown by Messrs. Lewis & Co., of Southgate, in the Temple); *Lelio-Cattleya* × *Schilliana*, a *White's* var.; the fine *L. purpurata* *Ashworthiana*, whose petals are almost as richly coloured as the lip, and peculiarly expanded *Cattleya*

labiata Mrs. E. Ashworth, a white variety, deemed by the Orchid Committee to be good enough for a First-class Certificate; *Odontoglossum crispum* Ashworthianum, one of the very best blotched kinds; and *O. Intepurpureum* Ashworthianum, a superb form of that species.

From Sir FREDERICK WIGAN'S gardens at East Sheen the best things exhibited and certificated during the year are *Dendrobium* \times *Wiganie* (nobile \times *signatum*), *Cattleya Mossie Beatrice*, *Lælia purpurata* Arthur Wigan, *Miltonia vexillaria* Memoria G. D. Owen, and *Oncidium varicosum* giganteum, all of the highest order of merit in their respective classes; and the singular and pretty *Epidendrum hastatum*.

FRED HARDY, Esq., Ashton-on-Mersey, brought out the very remarkable *Cypripedium*, Fred Hardy, which is probably an albino of *C. Charlesworthi*, although it may be a natural hybrid; *Dendrobium* \times *Clio*, Tytusfield variety, a very fine variation, very different from the other forms; *D. Clio album*, and a very fine form of *D. Schneiderianum*.

C. L. N. INGRAM, Esq., of Goddington, holds the record for the number of beautiful home-raised *Cattleyas* and *Lælia* *Cattleyas* raised by him, which have been certificated during 1896. Of these *Lælia* *Cattleya* \times *Chas. Darwin* is an ally of *C. Fowellii*; *L. C. Endora* (*L. purpurata* \times *C. Mendeli*), like a very fine *L. C. eximiat*; *L. C. Sir Wm. Ingram* (*C. anrea* \times *L. purpurata*), a very large and showy flower; and *L. C. Scarp*, *L. C. Ciero* (*C. intermedia* \times *L. C. elegans*), *L. C. Pytho* (*L. C. elegans* \times *C. Lodigesii*), all good in their way.

Of the *Cattleyas*, *C. Wm. Murray* var. *fulgens* (*Lawrenceana* \times *Mendeli*); *C. Eclipse* (*maxima* \times *Skinneri*); *C. J. Jupp* (*Lawrenceana* \times *Warszewiczii*); and *C. Preciosa* (*Ludlemanniana* \times *Lawrenceana*), were the best; and of fine varieties of imported species the *Cattleya Mossie* "Chas. Ingram," shown at the Temple; and *C. Percivaliana*, Ingram's variety, exhibited Jan. 14, were good examples.

Major JONES, Sunningdale Park, received a First-class Certificate for *Cypripedium* *exul*, *Jones's* variety, which in size and beauty far exceeds all others; and also a like award for the fine white *Diacrium bicoloratum*, which grows so well with him, that if an old plant, it was exhibited in a new guise; also a fine variety of *Miltonia canthiandra*, *Stanhopea eburnea*, and *Lælia monophylla*.

R. I. MEASURES, Esq., received a First-class Certificate for his charming pure white *Cattleya labiata* R. I. Measures; and also exhibited *Cypripedium* - *Woottoni* *C. Chapmani*, and other beautiful new hybrids, as well as some interesting botanical species.

Of others, new or distinct, as varieties, may be mentioned the *Lælia purpurata* Mrs. Crawshaw, *Odontoglossum* \times *Coralline* Rosefield variety, and the very handsome *Cattleya Trianoi* Crawshawana, of DE B. CRAWSHAW, Esq. *Cattleya* \times *Lawre-Mossie*, and *Odontoglossum crispum* Ardardroch variety, of R. BROOM-WHITE, Esq.; the *Odontoglossum crispum* Golden Queen, of W. THORSON, Esq.; the singular *Sopbro-Lælia* \times *Mariotti*, of Sir Wm. M. VERRILL; the *Cypripedium* \times *Cowleyanum* "Anna Louise," shown at the Temple, and *C. Schofieldianum*, by G. W. LAW-SCHOFIELD, Esq.; the pure white *Cattleya maxima* alba, for which HANAR BASS, Esq., received a First-class Certificate on November 10; the *Cattleya Dowiana* Maratitua, and *Cypripedium Calypso*, Stand Hall variety, of THOS. STATTOR, Esq.; the *Cattleya labiata* Ashford var., of G. S. BALL, Esq., one of the finest and richest in colour yet seen; *Odontoglossum crispum* "Princess," of V. VANNER, Esq.; the fine hybrid *Masdevallia* \times *Curlei* (*maculata* ? (*townsiana* ?)) raised and flowered by ALEX. CUTHLE, Esq., of Melrose; *Cattleya* - *Hardyana* Wheatley's var., *Odontoglossum crispum* Lord Sherborne, and *O. C. Victoria* Ellis, brought out by WELBORN S. ELLIS, Esq., of Dorking, an excellent cultivator of *Odontoglossum*; the *O. Humeanum* excellens and *O. Ruckerianum*, Mason's var., both very beautiful and distinct, of H. MANON, Esq.; Shipley, another clever grower of this genus; *Cypripedium* \times *James* Buckingham (*ex* - *enfielsenae* \times *bellatium*) of A. J. HOLLINGTON, Esq., of Enfield; and *C. Harri-Sander* (Harrisonian \times

Sanderianum), shown by W. C. CLARK, Esq., of Liverpool, and which is the first true cross with the extraordinary *C. Sanderianum*, from which much was expected. In this case the very darkly-tinted flower is more curious than beautiful.

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

LÆLIO-CATTFLEYA \times ROSALIND (C. TRIANOI, E.S., L.C. \times DOWNIANA, S.).

OUR illustration (fig. 1, p. 3) represents the above-named beautiful hybrid, for which Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, received a First-class Certificate when they exhibited it before the Orchid Committee of the Royal Horticultural Society on December 15 last. The general opinion of judges who saw it was that it is one of the very best hybrid *Orchids* of the year, and apart from that consideration, it is interesting as having for male parent a fine hybrid (*L. C. Downiana*), which appeared with the raisers, Messrs. Jas. Veitch & Sons, in 1878. There were only two plants raised, each differing from the other. They both passed into Baron Schroder's collection. About the parentage of *L. C. Downiana* there always existed doubts, but it is generally supposed to have been between *Lælia purpurata* and *Cattleya Dowiana*.

L. C. Rosalind has French-white sepals, and broad silvery-white petals, over which, except on the margin, there is a delicate tinge of pale rose-pink. The lip is rich yellow at the base, with clear white veining, the side lobes being rosy-purple, with bluish-white veins, and the front bearing a rich dark purple blotch.

PLANTS FROM ASIA MINOR.

Arum Disocaulis spectabile.—The leaves of this species are much more undulated than those of *Arum palaestinum*. It throws up a flower-stalk about 3 feet in height, bearing a spathe 20 inches in length, of a velvety texture; of a bright, reddish-purple inside, and shading into green above, spotted more or less closely with reddish-purple. The plant requires, according to the collector, Mr. W. Siehe, of Mersin, in Asia Minor, a bony humus-rich soil, and an abundance of water during the growing period.

Ichlerium coronata.—This beautiful species blooms in the autumn before the leaves appear. These form a close rosette of from 8 to 12 inches high. The flower-stalk is of about the same height, and a short shaft bears a broad velvety spathe, of a dark reddish-purple. The back is green, spotted with red. It grows on humus-rich, loamy soil.

Heliophyllum Rauwolfii.—One of the most interesting of early-flowering *Araids*. The spathe springs from between the leaves, and is black in colour and velvety in texture. The plant is of dwarf habit, and needs a chalky loam, or marl. All these three species succeed best in the full sun.

Anemone blanda vicia.—The true form of this charming *Anemone*, with its deep blue flowers, is seldom seen in gardens. In dry summers it will succeed if planted below bushes in a humus-rich chalky soil.

Bellevalia Hebræica vicia.—A charming broad-leaved variety. The bulbs throw up two long flower-stalks. The colour of the numerous flowers is exactly that of *Sella silvestris*. It grows on limestone soils.

Adonis vernalis.—This species, which also prefers a limestone soil, is certainly one of the most beautiful as well as the largest flowering species of the whole genus.

Adonis vernalis has somewhat smaller flower-spikes, tipped with red, and dark rose-coloured blossoms.

Adonis vernalis is a particularly free-blooming plant, hitherto unknown in cultivation. It has very delicate white flowers, flushed with pale rose colour.

Adonis vernalis.—A small-flowered rare species, which, unlike other varieties, blooms in the early spring, when the leaves appear. All these species of *Colchicum* prefer a limestone soil.

Corydalis ritefolia.—The tubers, which are 2 inches long, and are found 4 inches below the surface of a chalky soil, throw up from eight to fifteen flower-spikes in the early spring. These are about 4 inches long, and form a compact mass of numerous flowers, the colour of which corresponds with that of *Delphinium nudicaule*. These plants are readily forced in a cool-house. U. D., Berlin.

FORESTRY.

THE HOME TIMBER TRADE OF 1896.

SINCE writing on this subject a year ago, the prices of home-grown timber and forest produce generally, cannot be said to have greatly improved. Certainly, the demand for almost every class of timber has increased appreciably during the last three months, and for certain kinds it may truthfully be said that the demand greatly exceeds the supply. This is especially true with Oak, Ash, and Larch of good quality and large size, these meeting with a ready sale at fair prices. Large clean Oak fetches from 1s. 8d. to fully 2s. per foot, and several small parcels of special quality changed hands of late at prices even in excess of any just named. Ash, too, finds a ready market at 1s. 8d. per foot, and that of extra good quality was sold at an auction lately for 2s. per foot. Of course, the difference between clean grown plantation trees, and those from the field and hedgerow is apparent to everyone interested in the conversion of our home-grown woods, and the purchaser pays accordingly. Elm is still a drug in the market, and plenty, of perhaps not the best quality, can be got at the low figure of 6d. per foot, and a large batch of roughish trees recently was sold for 4d. per foot. Large and sound Sycamore finds a ready market at highly remunerative prices, and I recently sold a number of first class trees at 2s. 6d. per foot, but from 1s. 8d. to 2s. is nearer the mark generally.

Then, "matton" Willow, fit for bat-baking, finds a quick sale at high prices, and here again the supply falls far short of the demand. Beech, such as that produced on the Chiltern Hills, and in certain parts of Kent, Surrey, and Hertfordshire, sells readily at fully 1s. per foot, though 8d. is the average price in most parts of the country. The demand for this class of timber is very good at present; but rough, knotty small stuff can hardly be sold at even firewood prices.

Both Alder and Birch fetch 10d. per foot, especially in districts where the making of clog-soles is a part of the industry.

Larch sells perhaps more readily than any other of our home-grown timbers, the quantity of this on hand at the present time being small indeed. From 1s. to 1s. 3d. may be considered fair for that of good quality. Scotch Fir, on the other hand, is hard to get rid of even at the low figure of 6d. per foot, and there are lots at present offered below that price.

Oak bark is gradually deteriorating in value, and about £3 12s. was paid for large quantities during the past season. When we count 30s. per ton for barking and harvesting, and a further few shillings for delivery and supervision, the profits attending such a precarious commodity as Oak bark, even in an ordinary season, are hardly commensurate with the risks involved. Large faggots used to sell readily at 2s. per 100, but plenty are waiting to be sold at 12s. in the London market. Small faggots for fire-lighting—"pimps" they are called in southern England—can now be bought in the city at 2s. 6d. per 100—a contrast to the 4s. 6d. readily got not so many years ago. The split batten ends, now offered for sale by almost every grocer, have quite ousted the faggot from the market.

Coppice-wood, too, does not fetch one-half of what it did twenty years ago; that of sixteen years' growth, and composed mainly of Ash and Hazel, selling at the present time at from £5 to £9 per acre.

It is confidently to be hoped that the rather brisker trade and better prices of home-grown timber and other forest produce during the past three months will be fully maintained, if not increased, during the year 1897. A. D. Webster.

AMERICAN NOTES.

APPLE SHIPMENTS.

Up to the present the shipments of this year's crop of Apples from Canada and the United States to foreign markets have aggregated nearly

to pay expenses, but because of the pure impossibility of using the entire crop in America. The extreme competition of this season has already resulted in much refinement of methods, and in better marketing of the crop.

The so-called "Orchid-flowering" Cannas, introduced by Messrs. Dammann & Co., have received

opinion in this country. It is a strange coincidence that our American plant-breeder, Mr. Luther Burbank, should have originated, contemporaneously with the Messrs. Dammann & Co., and by the same cross, a *Canna* much like Austria. The stock of this *Canna*, named Burbank, has been bought by a Chicago firm, which will introduce it in the spring.

FIG. 1.—LELIO-CATLEYA x ROSALIND; SEGMENTS SILVERY WHITE; LIP YELLOW AT THE BASE, PURPLE IN FRONT. (SEE P. 2.)

2,000,000 barrels. These have gone very largely to Liverpool. Of the crop of 1895, less than half a million barrels, all told, were exported. This great increase is due to the unprecedented crop in Apple-growing regions of America. Especially in Canada, New England, and the States along the Great Lakes the crop is phenomenal. The extraordinary shipments to Europe have not been made because of attractive markets, many consignments having failed

prompt and general trial in America. This is particularly true of Italia. Opinions differ considerably as to the value of this new class to American gardeners; but it seems likely that the soft texture of the flowers, inherited from *Canna flagella*, will be poorly adapted to our dry, sunny, windy atmosphere. We have grown both Italia and Austria in our own greenhouses, and regard Austria as having the better blossom. This seems to be contrary to the usual

DEATH OF MR. LODGMAN.

The recent tragic death of Mr. E. C. Lodeman, Instructor in Horticulture in Cornell University, removes from us one of our brightest young horticulturists. He had already made for himself a wide reputation, though he was but a young man. His book on *Spawning of Plants*, editorially reviewed in the last volume of the *Gardeners' Chronicle*, is accepted as authority throughout the country. He

was also the author of many valuable bulletins from the Cornell Experiment Station.

SWEET PEAS, "CUPID."

This great novelty is now generally spoken of in a tone of disappointment. It has not been able to thrive with most American amateurs. The common opinion is, that while it is superb in California, where it succeeds remarkably, it is not suited to conditions prevailing elsewhere. The introducers, Messrs. W. Atlee Burpee & Co., with commendable enterprise, have secured a pink seedling from Cupid which retains the dwarf form of the parent, and which they promise soon to introduce.

PROFESSOR SARGENT.

We learn with great concern that the residence at Brookline, Mass., of our valued correspondent and eminent friend, Professor Sargent, the Director of the Arnold Arboretum, has been destroyed by fire. The Professor himself, who had recently met with a severe accident, which forced him to walk with crutches, was rescued with great difficulty. The manuscript for the ensuing volumes of the *Silva* has fortunately been preserved, as well as the library and collection of objects of art.

MARRIAGE OF MR. HARRY A. BUNYARD.

The marriage at New York City, on Tuesday, December 1, of Mr. Harry Bunyard to Miss Leuca Bach, is announced.

RURAL DECORATIONS.

It often occurs to me that much might be accomplished by a little encouragement on the part of our garden-loving British aristocracy for the culture of flowers by cottagers and others in rural districts. In the south-west of Scotland something in this florally artistic direction has already been achieved. The late Countess of Stair was a lover of horticulture, and it was her delight to inspire the love, and stimulate the refining cultivation of flowers by the cottagers in the vicinity of Lochinch Castle by offering prizes every year to those who were most successful in this work. I have of late been much gratified to learn that Mrs. McDouall, of Logan House, who is at once an eminent and an earnest horticulturist, is contemplating the annual offer of similar rewards to the cottagers on her son's extensive estates; and I doubt not that her example will be followed by other ladies who are equally interested in the promotion of what may be termed, without any exaggeration, the purest of sciences and the noblest of arts. Some of the fairest flowers that exist, such, for example, as the Madonna Lily, and the fragrant Provence Rose, also many of the most attractive of the clove-scented Carnations, have for years been the glory of English cottage gardens. I have proved from experience that in Scotland they can be cultivated with equal success. I am fortunate in having for my nearest neighbour a smith, not by any means an ordinary specimen of hard-labouring humanity, but a man of original mechanic capability, who is also perhaps in virtue of his originality of conception, an enthusiastic horticulturist. His great delight, when his day's work is finished at 7 p.m., is to attend through the whole length of the stumorous summer evenings to the requirements of his much-admired shrubs and flowers. At that season of the year his house is covered with Honey-suckle and climbing Roses. In his garden may be found many of the finest hardy Azaleas and Rhododendrons; among his interesting collection of the "Queen of Flowers" may be found such fine varieties as Duke of Edinburgh, which seems to bloom with equal beauty everywhere; Barouess Rothschild, of equally accommodating character, though seedless; Merveille de Lyon, Gloire de Dijon, the most widely cultivated of all climbing varieties; Beauty of Waltham, Margaret Dickson, and Belle Lyonaise. Among the Lilies which succeed admirably in his miniature garden, are *Lilium auratum*; *L. tigrinum splendens*, the brightest of its section; *L. longiflorum* var. *Harrisii*, and *L. speciosum*. All of these, though planted late, and in a situation with a cold, north-east aspect, yet well sheltered from the devastating winds, have succeeded beyond anticipation. I hope that many other who, while loving flowers, have hitherto neglected their culture, on the ground that

they are not a financial acquisition, may be inspired by his example to follow in his footsteps with equal success.

"When Epicurus to the world had taught

That pleasure was the chiefest good,
His life he to his doctrines brought,
And in a garden's shade this sovereign pleasure sought.

Whoever a true Epicure would be,
May there find cheap and virtuous luxury."

David R. Williamson, Mance of Kirkcaldie, Wigtownshire, N.B.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Barford, Dorset.

Cultural Methods.—Orchid cultivators possessing even long experience have always much to learn in the successful cultivation of a general collection of Orchids. After treating freshly-imported plants successfully for a season or two, we are apt to assume that the method that has been adopted is the correct one. But it often happens after that period that many of the plants commence to deteriorate, and some to disappear altogether. Every grower should try to improve year by year upon his own method of cultivation, and to apply what knowledge he can obtain from others who are uncommonly successful with particular species or varieties to the treatment of his own plants. In every Orchid collection there are probably some plants more or less difficult to cultivate, but many of these may become less troublesome with further experience. There should be practised moderation in all things appertaining to the growth of Orchids. This will result in even temperatures, careful watering, systematic ventilation, and a judicious amount of sun-light; and these are the means towards securing success. A few failures will occur that cannot be traced to inattention to either of the foregoing processes; for instance, in every conceivable way I have been trying to grow *Miltonia spectabilis* and allied species for several years past, during part of which time the plants did fairly well, but they were gradually declining to near their collapse point. Some of the plants started again with vigour, but unfortunately this lasted for only a short period. Several years ago I received a sample of what is known as American peat, which apparently consists chiefly of the roots of a hardy Fern (*Osmunda regalis*). The *Miltonias* were tried in it, and fortunately they grew and bloomed exceedingly well, even very small pieces which were nearly dead were awakened to new life. From the first the plants placed in this compost did better, and the improvement has continued; thus proving that heat, moisture, light, or air had nothing whatever to do with the cause of failure in this case. There are several similar instances that I could mention, especially in regard to those species of Orchids that produce small, thread-like roots; but of these I will endeavour to touch upon at the proper season.

Miltonias.—The present is a suitable time to examine such *Miltonias* as *M. spectabilis*, *M. Morelana*, *M. Elmti* and its variety *Lubbersiana*, *M. Peetersiana*, *M. stellata*, *M. Clowii*, *M. candida*, and *M. Regnellii*. Growth has already commenced, and if more root-space is needed, or any plants are not thriving satisfactorily, they may be repotted. Owing to the rambling habit of the two species first-mentioned, it is sometimes necessary to divide the pieces, and remake up the specimen. When doing this, cut away all the useless bulbs, and place the growing pieces together again, carefully pegging down to the compost such pieces as have but few roots. If the kind of peat mentioned above is not at hand, good fibry bracken peat is the best substitute for it, but the fine particles of dust must be shaken out of it. Keep the plants well raised above the rim of the pots; shallow pans are preferable for the dwarf-growing species, and pots for the stronger ones. *Miltonias* thrive best in a shady part of the Cattleya or intermediate-house, for if grown in too strong a light, the foliage becomes yellow, and falls prematurely. Very little water is needed until numerous roots are seen to be pushing out from the new growth. *Miltonia vexillaria* is now growing freely. This species should be supplied abundantly with water until growth is fully made up. On some plants the sphagnum-moss may not have grown well, and in such cases the dead moss should be pulled out, and living pieces pricked-in upon the surface. During the present dull weather extra ventilation should be afforded, to prevent the young

leaves becoming spotted. Do not damp between the pots until the external air is drier and the weather brighter.

Temperatures.—For the benefit of new readers of the *Gardeners' Chronicle*, and for beginners in Orchid cultivation, I give the following temperatures to be maintained by fire-heat at this season of the year:—East Indian-house, 60° to 65°; Cattleya or intermediate-house, 55° to 60°; the Mexican about 55°, and the *Odontoglossum* or cool-house 50°. The highest figures are for the night, and the lowest for early morning. During severe frosts or in very cold, windy weather, the temperatures may with safety be allowed to fall several degrees below the figures indicated, but it must be remembered that with a low temperature the atmosphere should be proportionately less moist.

THE FLOWER GARDEN.

By CHALES HERBIS, Gardener, Droppore, Maidenhead.

General Remarks.—There is but little to attract in the flower garden at this season, nor will there be before the Snowdrop, our earliest flower, appears above the soil, which may seem to occur if the weather continue as mild as at present. If the gardener should wish to transplant any clumps of these bulbs which may not have been possible at an earlier date because they could not be found, it may be safely done now, if the masses are not unduly divided up, and they are replanted at the same depth in the ground as that at which they had previously been. Where the walks in the pleasure-grounds are much over-shadowed by deciduous trees, they should be quickly cleared of the leaves, &c., for appearance sake, and to preserve the paths in as dry a state as possible. If a walk cannot get dry owing to accumulations of leaves on the surface, moss and weeds soon begin to spread, causing much labour and expense. After heavy rainfall following frost, the walks ought to be well rolled, which will have the effect of keeping them in good condition now, as well as throughout the summer.

Vacant flower-beds should be simply dug or trenched, according to the class of plant with which they will be filled in the summer. If *Pelargoniums* are to be planted in them, the soil must not be made very rich, otherwise foliage will predominate over flower. The *Calceolarias* prefer, on the contrary, a rich, cool rooting medium, and the beds which will be filled with the latter should receive a moderate dressing of rotted manure, and be deeply dug, adding clayey loam if the staple be of a light or sandy nature. Beds in which sub-tropical foliage plants will be planted should also be well manured and trenched, as in most instances the stronger and quicker the growth of the plants, the greater their effectiveness. In heavy soils it is sometimes desirable to raise such beds above the general level, so as to obtain greater dryness, and consequently increased warmth at the roots, throwing out the soil to a depth of 6 feet, and placing a layer 1 foot or more in depth of bricks, stones, &c., at the bottom of the bed, covering this with sods or half-lasted stable-dung.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Thinning-out Branches and Removing Moss and Lichen.—Where the fruit trees have not received attention in these matters, no time should be lost in getting the operations out of hand. That these cultural operations have been sadly neglected in the past, and are still much neglected, there is ample evidence on every side, and more especially in the orchards of Hants, Wilts, Dorset, Somerset, Devon, and the counties adjoining. To this fact may be attributed the deficiency in quantity and quality of the fruits produced, and the consequent low prices realised. The *Gardeners' Chronicle* has done much in the past towards remedying this state of things, but there is still much for its Editor and contributors to accomplish in the way of converting comparatively barren orchards into fruitful and profitable ones. The first step to be taken in this direction, is in the case of crowded orchards, to cut down or grub up worthless and aged or worn-out trees; this done, to thin the crowded heads of the remaining trees, not doing it all at once, but extending the work over three or four years, cutting out so as to let light and consequently air into the heads, fattening the prunings, if free from insect foes, for future use. Then scratch the moss and lichen off the trunks and main branches with pieces of bevelled-lath or hoop-iron, following this with a dressing of lime-wash into which a small quantity of fresh soap has been stirred, and may be applied

with a sledge, or if the trees are large ones, using the fruit-wall engine. If this be done on a calm day, much of the wash will adhere, destroying the remainder of the moss, &c., and the larvae of insects as well. The wash should be passed through a fine-meshed sieve before being used. In the case of short-stemmed and small trees and bushes, including those of the Gooseberry and Currant, lime and soot, or lime by itself in a powdered state, may be applied with good effect for destroying moss and lichens. Before dusting Gooseberry and Currant bushes, draw the soil back for a distance of 2 or 3 feet from the stems of the same, to enable the application to reach any insects or their larvae that may be lurking in the soil. This kind of preventive measure is best undertaken after the bushes have been pruned, in order to render the buds tasteful to the birds; and on this account too, it is prudent to defer the pruning of the Gooseberry until growth becomes visible, thereby affording the cultivator the opportunity of retaining those shoots which are the best furnished with fruit-buds.

Planting New Trees.—Approved varieties of Apples, Pears, and Plums, should be bought to take the place of the old ones, owing to being inferior or unproductive, have been or will be cleared away. The young trees should be planted in well-prepared holes, ranging in size from 18 to 24 inches in diameter and depth. If the soil be of an uniform good quality down to a depth of 3 feet, excavate it to the extent indicated, replacing the soil in inverted order to within about 1 foot of the ground-line, this being made cone shape for the reception of the individual trees. Before planting, prune back all damaged or straggling roots with a sharp knife, spreading all roots radially over the surface, then cover with 6 inches of soil, and take the tree by the stem and shake it out upward direction so as to let the soil trickle in among the roots in every part, and bring the soil to within about 6 inches of the surface after the remaining portion of excavated soil had been returned, and tread slightly over the roots if not too wet to do so. Should the highest water level be likely to come within 18 or 24 inches of the surface at any time, the trees should be planted on small mounds, putting stones, bricks, bats, or clinkers at the bottom of the holes, and turf grass-side down over them to prevent the infiltration of the mould.

THE KITCHEN GARDEN.

By W. PURE, Gardener, Highclere Castle, Newbury.

Digging and Trenching.—The principal operations in the kitchen garden at this season consist in digging or trenching all vacant quarters, leaving the surface in the rough condition favourable to the action of frost. A good depth of soil is essential for the successful cultivation of vegetables, and an endeavour should be made to trench or leaved-trench a quarter every year, so that the entire kitchen garden will be treated in this manner once in four or five years. If the soil is good to a depth of 24 to 3 feet, trenching may be carried out to that or any less depth, though it is not always desirable to bring very much of the subsoil to the surface at any time, as by so doing the loam may be rendered unfitted for the reception of small seeds for a considerable length of time. If a shallow soil, its depth may be increased by breaking up the bottom of the trenches, and using root-scrappings, decayed or charred vegetable refuse, or much of the cowsheds, &c., to it. Earthen trenching may be practised with advantage in most gardens, and being more quickly carried out than true trenching, it is possible to operate upon a larger area each year. This simply consists in taking out a trench 1 spit deep and the shovellers 1 yard wide, in making a start, wheeling this to where it may be desired to finish, and breaking up the bottom of this trench deeply; then fill it up with the top spit, &c., of the next, and so on, over the entire piece of ground, adding the manure (which should have been previously placed on the ground) as the work proceeds. If the ground be intended for a crop of roots, the manure should be dug into the bottom, or placed on the freshly-broken subsoil; and for other crops it may be advisable to mix a portion of it with the top spit. Take advantage of frosty days to wheel-out manure on to the quarters, spreading it at once if hard frosts seem likely to continue, as without this kind of protection the ground may become too hard to dig.

The Ordering of Vegetable Seeds.—Seed catalogues now coming frequently to hand is a reminder that the gardener should make out and dispatch his list of requirements to the seedsman, and the earlier he does this the better. Only well-tried varieties should be depended upon for the main supplies, it being sufficient to add a few of the novelties each year for

trial. Most of the nursery and seedsman in a large way of business sell collections of seed suitable for gardens of various sizes, which are wondrously cheap and good, and are preferred by many to the trouble incurred by making a selection, the only drawback being that the buyer may get too much of one article, or perhaps some that are not wanted at all, to the exclusion of something else for which he has a greater need.

Hobbeds are indispensable for the forcing of Radishes, Early Horn Carrots, Turnips, Potatoes, &c., either for planting in the open ground later on, or to grow to a notable size in the hotbed frames. There is no better time than the present month for making a start with most of such early crops, as sunlight is growing stronger, and the period during which the sun shines is lengthening. Commence by throwing together forthwith a heap of Oak or Beech leaves and fresh stable-manure, in the proportions of two parts of leaves to one of manure. Turn this once or twice in the heap before making up the bed, taking care to mix it thoroughly. In the meantime see that the frames, lights, &c., are cleaned and put in good order, in readiness for use.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Easton Castle, Leithbury.

Vines.—The Vines in the early-house, if started early in November, should now be pushing into growth, and may with advantage be given a little warmer temperature, or 50° to 55°, upon cold nights, and higher when the weather is mild. During the day the temperature may be maintained by fire-heat at 65°. Discontinue to syringe heavily; a careful sprinkling at closing time on sunny days will be all that is necessary, providing the surfaces of the floors and borders are kept well damped, and a supply of weak manure-water is maintained in the evaporating-pans. This latter method will be found one of the very best preventives of red-spider. Do not secure shoots until they are well advanced, as they will gain more strength if allowed a little freedom during this dull season of the year. The commencement of the year is a good time to start Hamburghs to supply grape fruit in July and August. If leaves and dung can be easily obtained, a bed of fermenting material may be made upon the border, and will prove very beneficial, besides rendering less firing necessary. The Grapes upon late Vines should have been removed before Christmas and bottled, if only to give the Vines a rest, for they will need to be quietly started again early in February. Aged Vines which have carried heavy crops of fruit should be afforded a good watering with liquid manure, especially those with borders inside. Give constant attention to the bottled Grapes, and remove bad berries to prevent delay. The bottles will also need to be kept filled with water.

Peaches and Nectarines.—Those who have to start their early house at the beginning of December or earlier, will now experience an anxious time, for the first month of the year is generally dull and sunless. Still, much can be done by a judicious use of fire-heat, and a constant circulation of air to cause the pollen upon the fast-opening flowers to gain sufficient buoyancy to effect fertilisation. A careful use of the camel-hair brush is almost indispensable in the case of trees forced thus early. If the borders are considered to be at all dry, a moderate watering with tepid water will do little harm, and will obtain a good set and a fair and setting is oftentimes the result of keeping the roots too dry at this, the critical time. Damp down the paths and borders after using the brush each day. The first week in January is a very convenient time at which to start Peach-trees, for before the flowers have opened we may expect better weather, and ripe fruits may be had from such trees at the end of May, or early in June. Give a little ventilation on all favourable opportunities, and make the most of the sun-heat available by closing early, and affording a light spraying with tepid-water at the same time. Continue the process of cleansing and tying, in later houses, if such work has not yet been completed. A little extra care in the cleansing of trees and houses now, will save much labour at a later period.

Figs.—In houses that were started on December 1, the trees will now be making signs of growth, and a little additional fire-heat may be afforded them with advantage. A temperature of 55° to 60° by night, with a corresponding rise by day, will be most suitable. No tree suffers sooner from drought than the Fig, and it is therefore imperative that the roots be kept sufficiently moist. In later houses, should it be thought that any of the roots have rambled from their proper quarters, though somewhat late the

matter may still be attended to. If vigorous measures are not adopted, there will be little fruit, but a rank and strong growth instead. It is better practice to keep Fig-trees in check by judiciously lifting them occasionally and root-pruning them, than by pinching the shoots, for unless the latter is done very early, you run the risk of getting soft, weak, unripened growths that will not produce fruits. If the process of lifting be carried out, take care to relay the roots in poor fibrous loam, with plenty of broken bricks, soft sawdust and lime-rubble added, for Figs root in such a compost, and richer food can better be given when watering after the fruit has commenced the final swelling.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Laton Hoe, Linton.

Seasonable Notes on Stove Plants.—At this period of the year it is necessary that the utmost care be exercised in affording water to stove plants, and to enable this to be done properly a knowledge of the requirements of each plant should be acquired. At this season Ixoras, Allamandas, Spathophitis floribunda, Dipladenias, Clerodendron Balfourianum, which have been resting since the autumn, should be kept moderately dry until February, when some or all of them may be started into growth. A strict watch should be kept on plants of Præcoxia and Croton, red-spider and thrips soon injuring their leaves. The smaller plants may be dipped overhead in a pailful of some safe and good insecticide, but it is better for the plants if they are not allowed to become badly infested so as to require dipping often than once a month. Should thrips abound, it will be advisable to vapourise the plants a few times with XU All, a valuable insect-destroyer if used according to the directions accompanying each bottle.

Plants on Work in the Plant-houses.—No time should now be lost in finishing the propagation of Chrysanthemums for supplying large blooms. Place the cuttings singly in 2½-inch pots, placing these in one or two small light frames fixed on the side stages of a greenhouse. The frames should be partly filled with sawdust or Cocoanut fibre refuse, in which the pots are plugged up to the rim, by which proceeding a very small quantity of water is required by the cuttings, nearly every one of which will strike. Only roots, stocky cuttings should be put, but the best stock of any variety is very limited. Here we cultivate a thousand plants every year, and never have any difficulty in striking cuttings according to the method described. A low span-roofed greenhouse is perhaps more suitable than a lofty one, or a lean to.

L'œna longiflora var. Harrisii intended to flower at the Easter season, should now be making a good growth, and the temperature of the intermediate-house will suit them admirably. They should be kept near to the glass and guarded from aphides.

Freesias.—These bulbous plants if required to flower in the months of May and June, should be forthwith potted up in good batches, using for the purpose 5-inch pots, and six bulbs in each. The best kind of soil for Freesias consists of loam, leaf-mould, or about equal parts, and sand sufficient to keep it open, using it when neither too wet nor too dry. Place in a cold frame, and afford no water before the roots become active. When the growths have reached 2 inches in height, the first batch may be placed in a warm house, and others may follow at intervals as may be required, thus keeping up a continuous supply of flowering plants in the above-named months.

Geraniums.—These plants, if in spathe, should receive weak liquid manure-water once or twice a week if the pots are small, and it may consist of the drainings from the stables or cowsheds which has been exposed to the air for 48 hours. If aphids should appear on any of the plants, fumigate the house forthwith, or the spathe will soon become discoloured.

The Show-house.—Attention should be given to the staking and tying of all plants in this structure, placing the plants as far apart as possible, so that overcrowding may be prevented, and the air circulate freely amongst them. Keep the foliage scrupulously clean and free from dust, fungus, &c.

Violets in Frames.—The generally mild character of the weather hitherto has suited these plants, air having been freely afforded. If foggy weather should set in, or hard frosts occur, rendering the airing of the plants less efficient, much care will be necessary in removing decaying leaves, and everything that favours decay and damp, giving air abundantly on bright days, and renewing the lights all together for an hour or two during the warm part of the day. Plenty of roots and broken litter should be kept handy in the event of very sharp frost.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER. Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR JANUARY.

MEETINGS.

SATURDAY, JAN. 2.	Soc. de France d'Horticulture de Londres Meeting
WEDNESDAY, JAN. 6.	East Coves Horticultural Improvement Society.
THURSDAY, JAN. 7.	Ayrshire Gardeners' Association.
FRIDAY, JAN. 9.	Isle of Wight Horticultural Association's Meeting
TUESDAY, JAN. 12.	Royal Horticultural Society's Committee.
WEDNESDAY, JAN. 13.	Renfrewshire Gardeners' Society's Meeting.
THURSDAY, JAN. 14.	Gardeners' Royal Benevolent Institution, Annual Meeting at Simpson's Strand.
WEDNESDAY, JAN. 20.	Society of Jersey Gardeners' Meeting.
THURSDAY, JAN. 21.	Linnean Society's Meeting.
SATURDAY, JAN. 23.	Royal Botanic Society's Meeting.
WEDNESDAY, JAN. 27.	Renfrewshire Gardeners' Society.

SALES FOR THE ENSUING WEEK.

MONDAY, JAN. 4.	750 lots of Boer Plants, Bulls, &c., at Stevens' Rooms.
TUESDAY, JAN. 5.	New and Rare Perennials, Roses, &c., at Protheroe & Morris' Rooms. High-class Poultry and Pigeons, Dogs, &c., at Stevens' Rooms.
WEDNESDAY, JAN. 6.	Japanese Lilies, Spiræas, Gladioli, Begonias, at Protheroe & Morris' Rooms. Roses, Fruit Trees, Shrubs, Bulbs, Lilies Palms, &c., at Stevens' Rooms. Carnations, Clematis, Peonies, &c., at Protheroe & Morris' Rooms.
THURSDAY, JAN. 7.	Cases of Aracaceæ as received, 60 cases of Japanese Liliaceæ, Orchids, &c., at Stevens' Rooms. Orchids, at Protheroe & Morris' Rooms.
FRIDAY, JAN. 8.	Scientific and Photographic Apparatus, at Stevens' Rooms.

LONDON: Dec. 30.—MAX. 52°; MIN. 41°.—HIGHEST TEMP. 52° N.E. England; Lowest, 44°, Shetland.
Corrected average Temperature for the ensuing week, deduced from observations of Forty-three years, at Chiswick.—36.4°.

A PEEP into the shop-windows of any of our large towns at the present season brings to mind the extent to which the kingdoms of Nature, and, perhaps, more especially the vegetable kingdom, are laid under contribution to supply not only the wants and necessities, but also the amusements and fancies of mankind. It also proves to us how is close our brotherhood with what geographically are far-off lands, but which steam and electricity have brought almost to our doors. No country on the face of the earth is too far removed from us at the present day to prevent it sending its natural products and manufactures into our markets—whether for good or otherwise is not a question for discussion at this season. Suffice it to say, that the demand each year seems to increase for these novelties. It must be confessed, however, that by far the largest increase in actual novelties in the English markets, is in manufactured articles, rather than in those of Nature's own production. Amongst food-products, it is true, that

our immense Australasian possessions have done much in quite recent times in adding to our fruit supplies, but these contributions have been chiefly confined to that well-known and always acceptable fruit, the Apple. The ever-welcome Orange is another illustration of increased supplies from new countries of production. It has recently been stated that during the present year as many as 3,000,000 cases of Oranges have been put on the English market, while forty years ago the average annual imports did not exceed 40,000 cases.

With the exception perhaps, of the Pine-apple and the Banana, which only a few years ago were too choice and costly for popular consumption, but both of which now find their way to the tables of nearly all classes, no fruit of tropical or warm climates has come to us as a marketable commodity. The Custard Apple, the Cherimoyer, and even the Mango, are not unknown in our shops, but their appearance is spasmodic, and to use a familiar term, they have not yet come to stay. As stated quite recently in a daily contemporary, efforts are being made to obtain some of these luxuries in a perfect state, and it is hoped that the West Indian Isles, who are going to make an attempt, notably Jamaica, may be able to transport their produce in such a manner as to cause many of the hitherto defects to disappear. We look in vain for fresh Lichis, which are amongst the most delicious morsels it is possible to conceive when in a perfectly ripe state, the pulp is then cool, slightly acid and refreshing, but still we do not find them in any other but the usual dried, somewhat shrivelled and blackened state.

Amongst the harder-fleshed fruits, and such as are not calculated to become very popular, even as a vegetable, may be observed at the present time, quantities of the Chocho, or Chow-Chow, as it is now generally called. This, as our readers will know, is the fruit of *Seschium edule*, and is not really a novelty, as it has been seen in our markets in small quantities from time to time for many years; but at the present season the fruits appear to be more generally known, forming, as they do, part of the stock of most greengrocers even in local towns. With regard to Christmas adjuncts to the usual floral decorations, all the old favourites seem well to the fore, especially in the way of dried grasses. The vulgar artificial colouring is not so much in evidence, but when dyes are used they are more subdued and artistic, as in the case of the various shades of green. Again, with the "fairy flowers," those mysterious fluffy balls so ingeniously manipulated from the seed down of some *Asclepiad*. The colouring of these are, this year, mostly in good taste, the delicate shades of pink, amber, and subdued reds, when arranged with a little Feather-grass, have a very pretty effect; and they have, moreover, the advantage of being real and not artificial. In the matter of artificial flowers, however, a very great stride has been made, and we recently saw some *Chrysanthemum* flowers, and bunches of small Crab fruits, that almost defied detection, and these were intended for the adornment of ladies' hats.

In the matter of utilising vegetable products to the best advantage, the Japanese are very strongly in evidence just now, particularly in the matter of choice inlaid wood-work, for which these people are so noted. Trays and cabinets of all sizes in which choice Japanese woods are so dexterously placed side by side in the best manner to show off their beautiful markings, are amongst the most attractive objects of the

so-called fancy shops. The most charming of these woods is the "Keyaki" (*Zelkova acuminata*), better known, perhaps, as *Planera japonica*. The plant is closely allied to the Elms, but the wood is of exceptional beauty, the dark, irregular, wavy lines imparting to it quite an unique character. It is considered a very choice wood in Japan, and is much used for ornamental and choice cabinet-work.

A peculiar material for the ornamentation of trays is the bark of species of *Pterocarya*, probably *P. rhoifolia* and *P. sorbifolia*. The bark is apparently flattened, and cut in thin sheets, thus cutting through the several layers, and showing numerous concentric and irregular dark-brown markings on a lighter or chocolate-coloured ground. This bark is said to be used in the manufacture of small objects known as Nikko-wa.

In the matter of walking-sticks and umbrella-handles, a variety of novelties appears at this season of the year. While there is always in this connection a great demand for what are called "natural" sticks, that is, such as Hazel, Oak, Furze, &c., as against those that are cut out of the solid trunk, it is often found that the vagaries of fashion demand things that Nature fails directly to supply, hence art has to come in to assist. This is seen this year in the demand for natural sticks and canes of certain fashionable shades of colour. The tendency in all departments of ladies goods this season has been to fix on green, in consequence the handles of umbrellas and parasols have to be produced to suit the prevailing taste. Thus the partridge-cane which is furnished by an unknown Palm, and which in its natural state is a remarkably pretty stick, is this year required not so much to imitate the humble partridge as the more ambitious peacock or parrot. Canes of various kinds imported from the East have to a large extent taken the place of English sticks, as Oak, Hazel, &c. Bent handles in the natural woods have also given place to mounts of gold, silver, and various stones, the prevailing colour of which is green, while some of the choicest are even mounted with beautifully painted Dresden china, so that the keen search of a year or two ago for novelties in the way of natural roots or twisted branches is now no longer, for a time at least, prosecuted.

WISTARIA SINENSIS.—This hardy trailer was, we find, introduced from China so long ago as 1816; it is, therefore, an old acquaintance, but is there one that is more valued, or which has a greater title to our regard? Our present illustration (fig. 2, p. 7) is taken from a plant in the garden of F. LLOYD, Esq. (gr. Mr. M. E. MILLS), Coombe House, Croydon. The length of the wall is 30 yards, its height 10 feet. From these details the beauty of the picture may be conceived. At its base is a collection of low-growing herbaceous plants. The plant usually flowers from spurs, but it often produces a second crop of blooms on the terminal shoots of the year. Captain WELBANK has the credit of bringing it to England, where it was at first kept in a Peach-house at a temperature of 84°, to the great advantage of the red-spider, but to the detriment of the plant. Then it was tried in a cool greenhouse, and at last it was found to be quite hardy! The fine plant at Chiswick is not, as is commonly said, one of the first imported, but it was raised (probably by layering) from the first plant introduced to the Rock's Nest, Godstone, by Captain WELBANK.

THE FORMATION OF A CHRYSANTHEMUM SOCIETY IN ABERDEEN.—A well-attended meeting of gardeners and amateurs was held in the Trades Buildings, Aberdeen, on Saturday evening, December 19, for the purpose of forming a Chrysanthemum Society for the city and north of Scotland.

SEEDS for the KITCHEN & FLOWER GARDEN.

WM. PAUL & SON,

ROSE GROWERS BY APPOINTMENT TO HER MAJESTY THE QUEEN,
TREE, PLANT, BULB, & SEED MERCHANTS,

Beg respectfully to announce that their

SEED CATALOGUE FOR 1897,

Is Now Ready, and will be forwarded, post-free, on application.

All Novelties of Merit will be found included, as well as many specially fine strains of already existing kinds of Vegetables and Flowers, and Customers may rely upon receiving the very best Seeds obtainable, and at the lowest possible prices for goods of really reliable quality.

PAULS' NURSERIES & SEED WAREHOUSE, WALTHAM CROSS, HERTS

TRADE MARK

CLAY'S MANURES

TRADE MARK

Have been proved, during many years of continuous trial by the most eminent Growers, to be

UNSURPASSED

For Vines, Roses, Chrysanthemums, Cucumbers, Tomatos, and all other Plants,
 Flowers, Fruits, and Vegetables.

Sold by the Trade in 6d. and 1s. Packets, and Sealed Bags:—7 lbs., 2s. 6d.; 14 lbs., 4s. 6d.; 28 lbs., 7s. 6d.; 56 lbs., 12s. 6d.; 112 lbs., 20s.
 Or direct from the Works, carriage paid in the United Kingdom for Cash with Order (except 6d. packets).

EVERY PACKET, BAG, and SEAL bears the Respective Trade Mark, which is the ONLY GUARANTEE OF GENUINENESS.

Crushed Bones, Peruvian Guano, Sulphate of Ammonia, Nitrate of Soda, Nitrate of Potash, Sulphate of Potash, Kainit, Superphosphate of Lime, &c., Tobacco Cloth and Paper.

BEST QUALITIES ONLY. WRITE FOR PRICES.

BARR'S SEED GUIDE for 1897

Is now in the Press, and will be ready in a few days, free on application.

Barr's Seeds are the best in the World for securing a supply of Vegetables "the year round," and for keeping the Flower Garden always gay, and with abundance of Flowers to cut for vases and bouquets; also Seeds of Plants for Greenhouse Decoration Summer and Winter. Catalogue on Application.

We guarantee all Seeds we send out to be of the finest selected strains, and of highest growing quality. They cannot fail to give the fullest satisfaction.

ALL SEEDS SENT CARRIAGE PAID ON RECEIPT OF REMITTANCE.

BARR'S FAMOUS "COVENT GARDEN" COLLECTIONS OF VEGETABLE SEEDS.

SENT CARRIAGE PAID AND PACKING FREE ON RECEIPT OF REMITTANCE.

The following collections have been made up with the utmost liberality, and our customers may also rely on having high quality seeds only included.

BARR'S 12/6 COLLECTION OF VEGETABLE SEEDS FOR ONE YEAR'S SUPPLY.

5 pints Peas, best varieties.	1 pkt. Cabbage for Spring sowing.	1 pkt. Lettuce, Cos.	1 oz. Spinach, Winter.
1 " Broad Beans.	1 " " " Autumn " "	1 " " Cabbage.	2 pkts. Turnip, best for succession.
1/2 " Dwarf French Beans.	1 " " Savoy.	2 oz. Mustard.	1 " Tomato, fine variety.
1/2 " Scarlet Runners.	1 " " Cauliflower, fine variety.	3 pkts. Onion, best kinds.	1 " Vegetable Marrow.
1 pkt. Beet, fine variety.	1 " " Celery, fine variety.	1 " Leek, fine variety.	1 " Thyme.
1 " Borecole " "	2 oz. Cross, curled.	1 " Parsnip " "	1 " Summer Savory.
2 " Broccoli for succession.	1 " " plain.	2 oz. Radish, fine varieties.	1 " Parsley.
1 " Brussel Sprouts.	1 pkt. Endive, fine variety.	1 " Spinach, Summer.	

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS FOR ONE YEAR'S SUPPLY.

14 pints Peas, best successional varieties.	1 pkt. Cabbage Savoy.	1 pkt. Endive.	1 pkt. Scorzonera.
4 " Broad Beans, best sorts.	2 1/2 oz. Carrot, best kinds.	2 " Lettuce, Cos.	2 oz. Spinach, Summer.
1 " Dwarf French Beans.	1 pkt. Celery, white.	1 " " Cabbage.	2 " " Winter.
1 " Scarlet Runners.	1 " " red.	1 " Leek, Cabbage.	3 " Turnip, best sorts.
1 pkt. Beet, fine variety.	1 " " Cauliflower, fine variety.	1 " Melon.	1 pkt. Tomato, fine variety.
1 " Borecole.	2 oz. Cross, plain and curled.	4 oz. Mustard.	1 " Vegetable Marrow.
3 " Broccoli, best varieties.	1 " " golden or Australian.	4 pkts. Onion, best kinds.	1 " Thyme.
1 " Brussel Sprouts.	1 " " American or Winter.	1 oz. Parsnip, fine variety.	1 " Pot Marjoram.
2 " Cabbage for Spring sowing.	1 pkt. Cucumber, frame.	3 1/2 oz. Radish, for succession.	1 " Summer Savory.
1 " " " Autumn " "	1 " " ridge.	1 pkt. Salsify.	1 " Parsley.
1 " Colewort, for bunch greens.			

BARR'S 42/- COLLECTION OF VEGETABLE SEEDS FOR ONE YEAR'S SUPPLY.

13 quarts Peas, 3 quarts Broad Beans, 3 pints Dwarf and Runner Beans, with other Vegetable Seeds in equally liberal proportion.

BARR'S 63/- COLLECTION OF VEGETABLE SEEDS FOR ONE YEAR'S SUPPLY.

20 quarts Peas, 5 quarts Broad Beans, 4 pints Dwarf and Runner Beans, with other Vegetable Seeds in equally liberal proportion.

BARR'S £4 4/- AND £5 5/- COLLECTIONS

contain a proportionately larger assortment to the foregoing. *All high quality Seeds.*

BARR'S CHOICE FLOWER SEEDS.

Our Catalogue contains a Select List of all the most beautiful Annuals and Perennials; it contains collections for all purposes, and many sterling Novelties for 1897; also some useful cultural hints on the raising of seeds and their after management.

CATALOGUES FREE.

BARR & SONS, 12 & 13, KING STREET, **LONDON.**
COVENT GARDEN,

Nurseries: Long Ditton, Surrey, Surbiton Station (S. W. Ry.).

Visitors invited to see our Daffodils in flower, April; Tulips in flower, May; other Hardy Flowers "The Year Round."

FIG. 9.—*VITIS VULPINA* AT COOKING IN USE, GANTON. (SEE P. 6.)

ROYAL HORTICULTURAL SOCIETY.—The following lectures have been arranged for the present year, and will be delivered at the Drill Hall:—

- March 9.—Professor Marshall Ward: "Microscopic Gardening."
- " 23.—Rev. G. Salmon: "Bud Transference, and its Effects on Fruit."
- April 13.—J. J. Willis: "Artificial Manures."
- " 27.—A. Dean: "Winter and Spring Bedding."
- May 11.—G. Masse: "Diseases of Orchids."
- June 15.—Professor S. H. Vines: "Physiology of Plants."
- July 13.—Professor Henslow: "Mutual Accommodation between Plant Organs."
- " 27.—W. D. Drury: "Familiar Garden Insects—Friends and Foes."
- Aug. 10.—J. Douglas: "Cross-Fertilising Florists' Flowers."
- " 24.—A. H. Pearson: "Plums."
- Sept. 7.—H. J. Veitch: "Nepenthes."
- " 21.—J. Wright: "Horticultural Exhibitions."
- Oct. 12.—C. C. Hurst: "Orchid Hybrids."
- " 26.—H. Selge Leonard: "Hardy Plant Borders."
- Nov. 9.—Professor F. W. Oliver: "Roots."
- " 23.—Professor Henslow: "Sporting in Chrysanthemums."

Meetings of the Society's committees will also be held on January 12, February 9, June 29, and December 14. The Temple Show will take place on May 26, 27, and 28; and the fruit show at the Crystal Palace on September 30, and October 1 and 2.

CHISWICK GARDENS.—A brief casual look round under the heavy haze of a London December fog sufficed to reveal that Mr. WRIGHT, the Chiswick Superintendent, has been utilising the open weather so far in getting a good deal of out-door work done, and next season will show to visitors some welcome changes. Amongst other things, very many comparatively worthless Apple and other fruit trees have disappeared, and the soil they occupied will be available for the extended conduct of useful vegetable and floral trials. It is pleasant, to be sure, that the merely pecuniary aspects of the gardens seem to be now less regarded, although these are important, and that they seem likely to be made in the future even more useful for purely experimental purposes. The fine collection of Plums obtained by Mr. BARNON, have all been lifted and replanted in one block, and in alphabetical order, Archduke leading off. These trees, all of bush-form, should have exceeding interest for pomologists in a year or two. A couple of nurserymen having presented a large number of young Peach and Nectarine trees for pot culture, these are now in pots, and with some old ones, fill a couple of the old lean-to houses, hitherto devoted to useless plants. In the propagating houses is a large collection of Fellows' Gift plants, sprays to catch sucklers, for sending out in the spring. The new entrance conservatory is now complete structurally, but as a plant-house is worthless until heated, pity it is the money spent in its erection had not been devoted to the building of a couple more of good roomy houses that could have been available for trials.

JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.—The part just issued contains full reports of the addresses delivered at Chester by Sir TREVOR LAWRENCE, Dean HOLM, and Mr. F. W. BURBIDGE. A full account of the Fruit Show at the Crystal Palace in October last is given, together with papers read on that occasion by Mr. E. J. BAILLIE, Mr. C. W. RABBITT COOKE, Mr. JOHN WATKINS, and others. There are reports on various trials at Chiswick, from a very limited point of view, and therefore not adding much to our knowledge; almost the only useful information in the reports, is that in which mention is made of the one Potato and the three Tomatos which gained unanimous awards.

COMING OF AGE, OF MR. GEO. HORSMAN.—A banquet in celebration of the coming of age of Mr. GEO. HORSMAN, eldest son of Mr. THOMAS HORSMAN, of Rosemount Nurseries, Ilkley, and of Eradford, Yorkshire, was given at the Lister's Arms Hotel,

Ilkley, on Saturday last, to which about ninety of the employees from Bradford, Frizinghall, and the Ilkley nurseries sat down, and some thirty additional guests participated in the later portion of the evening's programme.

"THE NEW GULLIVER; OR, TRAVELS IN ATHOMIA," by CHAS. T. DEUBEY, F.L.S., is a book whose object it is to bring home to the mind, in a humorous and amusing form, the manifold wonders of the world of Nature immediately around us, which, by their very familiarity, are apt to escape due appreciation. The Gulliver of these travels is benevolently endowed by the spirit of the age with the point of view of a Bluebottle, to the size of which he is suddenly reduced with that object. In this diminutive guise, and possessed (by virtue of his metamorphosis) of microscopic eyes and microphonic ears, plus the extra gift of a remarkable instrument, termed the Accelerator, he obtains a very fair insight into the marvels of earth, air, and water—all existent within the limits of his own little domain of house and grounds (Athomia). He furthermore experiences a series of most thrilling adventures and hair-breadth escapes amid the manifold forms of life encountered by him in his travels. The fifteen full-page illustrations depict a few of the most striking of these experiences; and the writer is much indebted to his friend, Mr. T. P. COLLINGS, for the admirable way in which the original rough pencil sketches embodying his ideas have been elaborated. The book is got up in a form particularly fitted for presentation to the budding naturalist of either sex.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—The monthly meeting of this society was held at 25, Westgate Road, on Tuesday evening, December 22. Mr. BULLOCK occupied the chair, and there was a good attendance of members. There was an excellent show of cut bouquets on the table, including Chrysanthemums, by Mr. MURRAY, Oakwood, and Mr. LAWSON, gr. Heathdale, Godforth. Mr. RUSSELL, nurseryman, Benthams, read an interesting paper entitled "An Edinburgh Nursery of the Past; and, a London Nursery of the Present." In the former part of his paper Mr. RUSSELL dealt especially with the once famous firm of PETER LAWSON & SONS, Edinburgh, about which he gave some very interesting particulars; discussion followed, in which many took part.

"NEW LIFE" DOUBLE PELARCONIUM.—The attractive little striped Pelargonium, exhibited by MESSRS. CANNELL at the last meeting of the Royal Horticultural Society, owes its peculiarity to the substitution of white or striped petals for the stamens. Thus, in the first place, we have the green sepals with one nerve, and running out into a point; then the petals, obovate in form, that is, broad towards the free end, and tapering towards the base, the nerves being numerous and spreading. These petals are some of them wholly scarlet, others striped with scarlet. Within the true petals come the staminodes, or modified stamens, some pure white, others variously striped, as in a Carnation. In none of the flowers, so far as we have seen, although the pistil is fully formed, are the stamens perfect. In the hands of Mr. CANNELL there is no telling what it will come to.

THE NURSERY BUSINESS OF MESSRS. JAS. VEITCH & SONS.—We learn that, for family reasons, MESSRS. JAMES VEITCH & SONS, of the Royal Exotic Nursery, Chelsea, have decided on converting their business into a private limited company, under the name of JAMES VEITCH & SONS, Limited. No part of the capital of the Company will be issued to the public, and the conversion will not affect the general conduct of the business, which will be carried on as heretofore under the direct superintendence and management of Mr. HARRY J. VEITCH and his two nephews, Mr. JAMES H. VEITCH and Mr. JOHN G. VEITCH, who will act as Directors of the Company.

ERNEST GUSTAVUS LODEMAN.—It is with great concern that we reproduce the following extract from *Garden and Forest*. Our acquaintance with Mr. LODEMAN was only scant, but we had formed a high idea of his capacity, and admired his book on "Spray-

ing" as a classic.—ERNEST GUSTAVUS LODEMAN, instructor in Horticulture in Cornell University, and Assistant Horticulturist to the Cornell Experiment Station, died by his own hand during an attack of acute melancholia, in Mexico, Oswego County, New York, on December 2. Mr. LODEMAN was born in Neuchâtel, Switzerland, on May 3, 1867. When he was two years old his parents came to this country [United States], and in 1870 his father became Professor of Modern Languages in the State Normal School of Michigan, from which institution the son graduated in 1889. In 1890 he began in Cornell University the professional career which proved remarkably useful and fruitful. In 1895 he received the degree of Master of Science from the university, and his thesis, *The Spraying of Plants*, was subsequently published as one of Macmillan's Rural Science Series, making a book of some 400 pages. At the date of his untimely death he was a candidate for the degree of Doctor of Philosophy, having taken up for his thesis a philosophical and botanical study of the cultivated Begonias, and he had collected a greater number of species and type forms of the genus than exists in any other American collection. In the college he had particular charge of classes in the propagation of plants, spraying, greenhouse construction, and pomology. In connection with the experiment-station work he prepared many important bulletins, and the spray-calendar idea which originated with him is now an established type of publication. When the station was asked to extend its work directly among horticultural communities, Mr. LODEMAN threw himself enthusiastically into the work, and soon became a personal favorite among the fruit-growers of western New York. All the work upon Grapes and Strawberries, two large industries in the State, was entrusted to him, together with the treatment of certain plant diseases. His last journey out to Oswego County was to inspect experiments in fertilising Strawberry fields, and here, under some impulse induced by the strain of overwork, he met his tragic end. Personally, Mr. LODEMAN was tall and well knit, and he usually enjoyed excellent health. He had the modesty and patience of the true student, and although at times he felt a depressing distrust of his own ability, he was prosperous and happy in his work. He was an excellent linguist, speaking French and German fluently, and having a useful knowledge of other languages. His private life was spotless, and he had a sweetness of temper and true manliness of character which endeared him to all with whom he came in contact.

THE SILVA OF NORTH AMERICA.—The tenth volume of Professor SARGENT'S *Silva of North America*, was, says *Garden and Forest*, published on the 28th of November. It contains figures and descriptions of the arborescent species of Yucca which grow north of the Mexican boundary, the arborescent Palms of the United States, the Cupressaceae and Taxaceae, and the following genera of Coniferae—Juniperus, Cupressus (including Chamaecyparis), Thuja, Libocedrus, Sequoia and Taxodium. Two additional volumes will complete the work. The eleventh, now in course of preparation, will be devoted entirely to the genus Pinus, and in the twelfth and final volume will be described the Spruces, Firs, Hemlocks, Larches, and a few trees of earlier orders which have been found since the publication of this work was begun.

NEW SWISS HYBRID LAVATERA.—Should any of your readers, remarks Mr. W. E. GIBBERTON, not be acquainted with the colour and appearance of the two supposed parents of the above-named interesting natural hybrid, mentioned and partially described by M. MARC MICHELLE on p. 761 of your last volume, it may interest them to learn that they can see coloured plates of *Lavatera trimistis* in the 4th vol. of the *Botanical Magazine*, No. 101, and of *L. maritima* in 10th vol. of *VAN HOUTTE'S Flore des Serres*, No. 1007. As this interesting new plant is a yet without a distinctive name, I would venture to suggest that it might be correctly and appropriately named *Lavatera nicotiana*, after the name of its owner's residence, Chateau du Crest.

PRESERVATION OF THE GIANT'S CAUSEWAY.

—The National Footpath Preservation Society is making an urgent appeal for funds to defend the public right of access to the well-known Giant's Causeway, in Antrim. This marvellous natural formation has always been accessible to visitors, the numbers of whom are estimated to be now about 80,000 annually. Prompted by the modern commercial spirit, a company has lately been formed "for the purpose of enclosing the Causeway and making a profit out of it by charging a toll for admission." A defence association has also been formed, whose object it is to take legal proceedings to check, if possible, this enclosure of what is alleged to be public ground, and to establish the facts that the company claiming it is not exclusively entitled to the place, nor can restrain persons from trespassing thereon in future. All who are interested in the question of granting free public access to the more prominent marvels of Nature, are requested to forward a subscription to Sir W. McCAMMOND, Fort William Park, Belfast; or to HENRY ALLNUTT, Esq., 42 Essex Street, Strand, W.C.

EVOLUTION OF PRIMULA OBSCURA.—Messrs.

WILLIAMS & SON send us flowers of *Primula obconica*, which show very clearly the advance that is in progress in this species; the "eye" of the flower is becoming more deeply coloured, the petals are becoming more deeply fringed at the edges, so that before long we shall have distinct types, groups, strains, variations, or whatever term be preferred, just as we have in the case of the Chinese Primrose. Mr. BAIN, gardener to Sir T. LAWRENCE, showed a similar series on Tuesday last; and now that attention is being drawn to the matter, we may expect many others. How is this variation brought about? Not by cross-fertilisation in this case; not by the action of the "environment," as Professor HENSLow would probably assert, seeing that the conditions are practically identical, whilst the variations are—variable! Possibly by reversion; but of this we have no proof. It is obvious that we do not yet know the reason why, but that circumstance supplies all the greater incentive to collect fresh facts, and institute fresh experiments. We may never in our time penetrate into the heart of these mysteries, but every new fact gained is a help forward.

NEW PUBLICATIONS.—*Palmer für Pitt-freunde.*

A guide to Fungus-lovers. Von EDMUND MICHAEL (Zwickau); FRISSTER & GORRIES. We call attention to this small volume, devoted to the illustration of the most frequently occurring edible, suspicious, and poisonous fungi, for the purpose of recommending it to beginners. The plates are excellent.

Programme de l'Exposition de la Société Royale d'Horticulture et d'Arboriculture à Bruges. This exhibition will be held in the Halles on April 11, April 12, and April 13, 1897, and monthly meetings in connection with them on the third Sunday of each month, from 11 to 1 o'clock, at 8, Rue des Aiguilles.

Price List of the Flower Show of the Crossipore Practical Institution of Horticulture, Floriculture, and Agriculture. This exhibition is to be held in the Seven-Tank Garden, Dum-Dum Road, on Feb. 5 and 9, and there will be twenty-five classes for exhibits of well-arranged groups and cut flowers; for vegetables, Roses, Camellias, Lilies, &c. A prize is offered for "a floral crown with floral characters of H.M.G. Majesty the Queen." This is to be competed for "by ladies only."

HOME CORRESPONDENCE.

MISLETO.—Mr. Drury's "Medicinal Mistletoe" (last vol. p. 787) may be the Cactaceous genus *Hipsoxalis*, one or two species of which genus so closely resemble *Viscum* or *Phoradendron* in habit of growth and in fruit as to be quite capable of deceiving the elect even, unless they look at the plant very closely! As to our native *Viscum* (p. 785), the male and female plants differ much in habit and size of leaves. Male plants often have leaves 2 to 3 inches long and an inch in width; those of female plants are much smaller and narrower. F. W. Burbidge.

CARNATION SOUVENIR DE LA MALMAISON AT OSBERTON.—I was much struck last week at the unusual sight at this time of the year of 400 of these beautiful plants in bud and bloom, and from eight to ten blooms on a plant, with dark green only foliage to the rim of the pot, with not the slightest sign of disease. They were about 2 feet high, about as much in diameter, and in perfect health. I noticed the flower-buds were well-thinned, only one flower on a shoot, and when I learned that they were the same plant, I saw in bloom last July, I was much interested. They were then in 32-pots, with one bloom to a plant. I thought then they were the healthiest plants I ever saw. Unfortunately, at the time of my visit Mr. Crisp was absent, so I could not get any cultural details, but perhaps he will oblige if he should read this note, and thus afford information useful to many cultivators, amateur and others. R. S., Nottingham.

THE VALUE OF ASHES AS MANURE.—In reply to the question of your correspondent, Mr. T. Fletcher, in a recent issue, I may say that wood-ashes are doubtless a valuable mineral manure; indeed, so firm is the American farmers' faith in the value of ashes, that many persons have drawn from it the false inference that potash, which is the chief constituent of value in ashes, is not only the main thing, but the sole thing needful to fertilise the land, and to bring up those sections of the country which have been run out by careless cropping. But it is not fair to class wood-ashes as an exclusively potash-manure. Besides potash, wood-ashes contain 1 or 2 per cent. of phosphoric acid, and various other ingredients which are of value to plants, notably a little magnesia, and a great deal of carbonate of lime. The ashes of coal contain a trace only of potash, not much, if any more, than is found in ordinary loam, or than in many kinds of sand. Whatever merit pure coal-ashes may really possess must depend upon their mechanical condition—their fineness and freedom from cinders, which fits them to do good on clay soils, and on soils rich in humus, such as old garden soils, leaf-moulds, peaty soils, and those reclaimed from bogs. Of course, the value of ashes may vary considerably according to their source. They are richer or poorer in potash and other useful ingredients, according to the kinds of plants from which they are derived. The ashes of twigs or brush-wood will always be worth much more than the ashes of heart-wood taken from the middle of an old tree, and in general the smaller and younger the wood burned, the better will be the ashes. Consequently we find the composition of wood-ashes varying from 5 to 20 per cent. of potash. On the average, we may say that a bushel of ashes weighing 18 lb. will contain 4 lb. of potash and 1 lb. of phosphoric acid. Wood-ashes may be used with advantage to Vine-borders, and I have seen splendid crops of Carrots grown by their use; the soil, however, must not be deficient in nitrogen, therefore dung, or some other nitrogenous manure, must have been incorporated into the soil previously. Potato crops respond to a liberal dressing of ashes; as much as 100 bushels per acre may be used. Pasture-lands and lawns are benefited by an application of wood-ashes applied in the early spring months. Wood-ashes are best suited to light and heavy soils. Coal-ashes are best suited to heavy soils, or those containing an excess of vegetable matter, such as peaty or humus soils. J. J. Wallis, Harpenden.

TOMATOS.—Mr. Wythes' article on the cultivation of this vegetable reminds me of the time when I tried to fruit the same Tomato plant several years in succession. I transplanted one plant in a narrow pit formed with bricks against the back wall of a Peach-house, at the end of the house, training it up and along wires until it attained a length of 12 feet. I succeeded in resting the Tomato plant at the same time as I did the Peach trees, and managed this for two seasons, but after this it would not live and fruit for me any longer—I suppose it did not get sufficient care. However, it bore a good crop two summers, and a very pretty picture it made—so much so that people came long distances to see it. The variety was smooth fruited, but at the time I grew it I do not think it had a name. Joseph Meredith, Rossmore, Bishop's Cleeve, Staffs.

THE INTRODUCER OF LAPAGERIA ROSEA.—We have been lately furnished in *Gard. Chron.* with a good illustration of the manner in which mistakes are made, for on p. 857, 1st vol., Mr. F. W. Burbidge, writing in reference to the fruiting of *Lapageria rosea*, says he believes the plant in question was introduced by Thomas Lobb; then in the number for Dec. 19, Mr.

A. Outram states, without any element of doubt, that it was introduced by Thomas Lobb, which will doubtless be news to the House of Voitch, the employers of the two Lobbs—Thomas and William, for Messrs. Veitch, in their *Manual of Coniferæ*, p. 258, in the course of an exhaustive article on William Lobb, states that starting from England in 1845, he made his way to Southern Chile, and among his earliest introductions from that region were *Lapageria rosea*, *Escallonia macrantha*, *Embothrum coccineum*, *Philisia lyallii*, *Desfontainia spinosa*, and others. "Thomas Lobb, whose name has been brought so prominently forward, was the means of introducing many plants from Eastern and South-eastern Asia, his name being perpetuated in *Arciles Lobbii*, *Eschynanthus Lobbii*, *Bolophyllum Lobbii*, *Cryptomeria Lobbii*, and *Sedgwickia Lobbii*, *Ruscus*.

GROS COLMAN AND GROS MAROC.—In the Royal Horticultural Schedule, these two varieties are bracketed together. A very good idea as to the merits of the two varieties. The Royal Horticultural Society's Schedule reads thus:—Class No. 7, Grapes: Gros Colman or Gros Maroc, three bunches; these two Grapes were staged in the same class last September at the Crystal Palace Fruit Show, and Gros Maroc beat Gros Colman. The unsuccessful exhibitors who staged Gros Colman were disappointed, which has led to the present discussion in the *Gardeners' Chronicle*. At p. 539 of the *Gard. Chron.* for Nov. 14, Mr. Temple remarks upon the above. "The idea of putting Gros Maroc before Gros Colman is a novel one at least, to northern gardeners." Mr. Temple forgets that he was a judge at Edinburgh, and ought to have seen the Grapes there. And I am under the impression that he should pay closer attention to exhibitions at home before he criticises the Royal Horticultural Society's awards at the Crystal Palace. As I stated, Gros Maroc in the month of September is superior to Gros Colman, and as a proof of that statement, I draw Mr. Temple's attention to what has taken place within 50 miles of Carron Gardens, and I that Gros Maroc was first against any other variety of black Grape in Edinburgh last September, beating Muscat Hamburgh and Madresfield Court. This does not prove that Gros Maroc is superior to the two last-named varieties of Grapes, and my estimate of Gros Maroc is that it stands fourth on my list in point of quality against any other black Grape in the month of September; but all judges cannot see alike, and differ as do the doctors. Why should not voting papers be sent to all successful cultivators of Grapes, and let us have black and white Grapes classed in their proper position by the votes given for each variety? How can we best get the varieties of the white which are considered synonymous, and cannot therefore be shown as distinct varieties. This would be a great advantage to many of the younger men, and a step, I think, in the right direction. A. Kirk, Northcote, Alton, N.B.

THE PROPOSED HORTICULTURAL INSTITUTE.—Mr. Jas. L. Wood, in his communication, tells us that "the need of a metropolitan horticultural institute has been recognised for years." For the sake of argument, we will admit this; indeed, it is but fair we should do so. It was recognised a few years ago, and it is well known that a special effort was made to supply this want. Baron Sir H. Schroder not only formulated a scheme, but backed it up with the promise of a munificent donation, and induced his friends to subscribe in a more liberal manner than was ever known before in the annals of horticulture. The sum of £30,000 was required, and it came to the point that the Fellows of the Royal Horticultural Society would have subscribed an average of £5 each, the amount would have been raised. All felt the need, the scheme was formulated on paper, and though a few earnest horticulturists promised about £20,000, the general public refused to lend the remainder. A central site was available at that time, probably it is not so now; if it is, it can only be obtained at a very high ground-rent. Most of us know what has been the result of previous efforts in this direction. In 1869 there was to be a union of all the sciences, including horticulture as the chief, at South Kensington. It was under the special patronage of the Queen and Prince Consort, also the Royal Horticultural Society. I attended the first opening show, and the last; but after the first spurt was over, it was never a success, and, as is well known, the Royal Horticultural Society nearly came to grief over it. Failure is written over nearly all these large horticultural schemes opened with a great flourish of trumpets. I attended the opening show of the Alexandra Palace

or Park, the Royal Aquarium also; the latter is central enough surely; it was to be a home of horticulture, and money seemed to be plentiful enough at first; but what is it now? The National Chrysanthemum Society have made it their home; and, so far as I know, this is the only trace of horticulture about it. Surely, Mr. Wood and his friends will not ignore the lessons to be learned from previous failures. I would be the last to throw cold water on any feasible scheme likely to benefit gardeners; but the whole thing is far too complex even to build upon. The "need" and the "opportunity" need not be discussed, but the "start" is very important. If a body of trustees is to be elected, it can only be from the leading horticulturists near London, all of them probably Fellows of the Royal Horticultural Society, and interested in the work of that Society, and all of them that would be likely to subscribe, having a full knowledge of the failure I have already alluded to. The second step, and the third step, is to solicit the aid of the Lord Mayor and of the Prince of Wales; they may render help, or they may not; but my own opinion is, that such help to horticulture has not been of any value in the long

pital courts, charity courts, sale of work, children's help societies; national festivals of the three patron saints of Scotland, Ireland, and Wales are to be held, but why St. George of England is left out in the national jubilation it is hard to say; but what has all this to do with a horticultural institute? The fact is, the scheme may be anything you like. An exhibition of matches, kid-gloves, millinery, or state carriages. It may be a picture gallery on a large or small scale, or a charity organisation society. These things are all very well in their way, but why they are linked with horticulture I cannot conceive. Mr. Wood says, "If we sink every other consideration and join hand in hand, the horticultural institute will surely be founded." "Hear! hear!" I cry with all my heart, but let it be an institute that gardeners and lovers of gardens and flowers can support. What is really wanted is a building on a modest scale, not for large flower shows, but such a building as the Drill Hall of the London Scottish Volunteers in James Street, Westminster, with offices to carry on such work as is now done by the Royal Horticultural Society, a room for a library, &c.; but the catering for refreshments would be a

I can remember; they were procured from Messrs. Lucombe, Pince & Co., Exeter, and when sent out they cost 10s. 6d., each as grafted standards (not from the ground). They did me nothing in the way of fruiting, and grow as they like, unless a branch should get a little out of place. The trees stand in an orchard, and grow very well; the ground is manured every year more or less, and liquid manure from the farmyard is supplied as well. I do not know anything about wall-fruit cultivation, for if a tree will not grow in an orchard, it is of no use to me, and therefore my remarks are on that kind of culture. These trees are from 25 to 30 feet high, and about the same in diameter, and the stem is from 1 to 1½ foot in diameter. J. C.

CEDRUS DEODARA.—Your correspondent, Mr. Simpson, on p. 696, last vol., brings this tree before the notice of the readers of the *Gard. Chron.*, and wishes to know if anyone has ever heard of it failing as a plantation tree in this country? From what I have seen of its growth I am of opinion that in favoured situations it might make a timber-tree, but for it to do well the ground must be light and rich, with a dry sub-soil. The trees here, which were planted about forty years ago, have attained a height of 60 or more feet, with a girth of from 6 to 8 feet at 5 feet up the stem. They have grown larger than Limes that were planted at the same time, being both higher and thicker in the bole. Here, however, the trees cannot be said to be hardy, as they suffered much from the severe winter two years ago. A gentleman who resides in the village here, and who was in the East India Company's service, told me that shortly after the Deodara was introduced he was commissioned to procure 100 tons of seed, so sure were the nurserymen and others connected with forestry in this country of its becoming so popular as to supplant the Larch, Scots Fir, Norway Spruce, and other hardy Conifers, that the seed was sown largely. Of the millions of plants thus raised but few are to be found alive at the present time, and instead of them supplanting other forest trees, most of what remain are to be found as ornamental trees in parks and gardens, thus bearing out Mr. Nicholson's remarks, that as a forest tree it is a failure. I know of none that have arrived at extraordinary dimensions; even on the best of ground. On shallow gravelly soil the tree makes but poor progress, and is often cut by frost. From what I have seen of *Abies Lowiana* I should say this was far better for timber planting. Trees of this latter that have only been planted twenty years are already taller than the Deodar. The Douglas Fir is so liable to have the points of its shoots eaten out by squirrels, which stop its upward progress, otherwise it would make a grand forest tree. H. C. Prinsep.

CHRISTMAS TRADE IN FRUIT.—In your article on our Christmas supplies you state that the bulk of the fruit was foreign, which, of course, is quite correct as applied to Apples and Oranges, but I think it will be interesting to your readers to know that there were never so few foreign Grapes sold, most of the best shops not buying them at all; and whereas the Alcaerias used to be a staple article for Christmas trade, the English growers now give us a better article in such quantities as to make the better class consumer quite independent of the foreigner. My sales of English Grapes for the four days preceding Christmas were about 4000 baskets, weighing 22 tons, 9 cwt., 2 qr., 14 lb., the heaviest day being Tuesday, when we sold over 7 tons 11 cwt. And more than that, we are turning the tables on the foreigner by sending regularly to America, and almost daily to the Continent, both Cucumbers and Grapes. *Geo. Monro, Covent Garden.*

CYCLAMENS NOT OPENING THEIR FLOWERS.—That thrips, like green fly or any other insects attacking Cyclamens, must be detrimental to them goes without saying, but does not your correspondent, Mr. E. O. Orpet, in *Gard. Chron.*, Dec. 19, p. 759, attribute too much importance to their ravages? Cyclamens in perfect health are very little troubled with insect pests, but immediately they receive a check in their growth these little enemies appear, when it is at once assumed by many growers that the insects have caused the stunted growth, whereas it is the neglect of the plants which has encountered the pest. Many think that the white grub or maggot that attacks the corn or bulb of the Cyclamen by boring holes into it is at the bottom of all the evil, whereas if the plants were in vigorous health there would be no grubs, as it feeds on the unhealthy or decaying tuber only, and multiply thereon, in a similar manner to the Encharis moth, which is never found upon bulbs which are in a healthy state, but as soon as the plant receives a check the dreaded mite appears and more

FIG. 2.—*LELIA LUMILA* VAR. *ALBA* "E. ASHWORTH"; FLOWER TUBE WHITE; BASE OF LIP YELLOW. (SEE P. 1.)

run. It is easy enough to make a grand opening ceremony, with the Lord Mayor, the Royal Horticultural Society, and 400 horticultural societies, with the Livery Companies to boot, if you can get them. With head-gardeners subscribing £25 and £12 10s. each, but how many gardeners would subscribe these sums for such a purpose? It is all very well to say, "United we stand, divided we fall," but how you are to unite such a conglomeration of interests as are defined at p. 762 of last vol. I cannot conceive. Horticultural Institute indeed! We are informed that "all interests will have a fair consideration." There are to be—refreshments by a "first-class caterer"; music, "only those of the highest class would be considered." "Picture-galleries and statuary," only the highest class, of course; exhibitions of appliances; high class concerts and conversations. An indefinite number of counts to be set apart for all classes of trades. There are some seventy-five city guilds or companies which might claim to be represented, and if they all subscribed they would have some right to representation. Mercers, Grocers, Drapers, Goldsmiths, Skinners, Merchant Tailors, Haberdashers, Ironmongers, Vintners, Clothworkers, &c. I suppose we must draw the line somewhere, and I would suggest Salters and Fishmongers, but they might not agree to it, as they are two of the twelve chief corporations of London. We come next to the hos-

failure, and is quite unnecessary in London. The Royal Horticultural Society is now doing a good work entirely in the interests of horticulture, and as such claims, and receives freely, aid in this work from ladies and gentlemen who can appreciate such work. It may be said that Mr. Wood's scheme is not intended to interfere with the work of the above society. This may be so, but it does not matter what people intend or say when they formulate such schemes, for it is quite certain that very few people would subscribe to two central societies; and many of the more thoughtful members and Fellows of the Royal Horticultural Society will pause before they give their money to anything in the nature of an opposition. For my part, I consider the whole thing as a flight of fancy, and altogether impossible to be worked for the benefit of horticulture. If the London livery companies liked to have such a building to display their insignias of office, or their work in gold and silver, well and good; but do not let it be called a horticultural institute. J. Douglas.

HUYSHÉ'S VICTORIA AND BERGAMOT PEARS are grown here as standards, and they are very prolific when the season is right for blooming and setting, that is, if there is a nice dry time at blooming—they are then generally well cropped. I bought them between thirty and forty years ago as nearly as

often remains until the bulbs are quite decayed. The more successfully plants are cultivated the less trouble will be found by insects attacking either the roots or foliage. *F. C. Edwards, Author of "Cyclotenus and How to Grow Them."* [We fear that weevil-grubs at least are not very particular what they eat, and we have seen mites on the soundest and healthiest bulbs. Ed.]

NOTICES OF BOOKS.

ROUND THE YEAR: A SERIES OF SHORT NATURE-STUDIES. By Professor L. C. Miall, F.R.S. (London: Macmillan & Co.)

The subject-matter of this volume may be guessed from the title; it is, in fact, the journal of a naturalist, printed for the benefit of "observers (especially young observers) of out-of-door Nature, teachers of elementary science, and all who care for live natural history."

Professor Miall has this great advantage over other writers of natural history notes—he is one who not merely thoroughly understands his subject, but, himself a thinker, would lead his readers also to consider the why and wherefore of such facts as they observe, and would have not to be content with merely knowing that leaves fall, buds open (and so on) at certain times.

As is to be expected in a book of this kind, the information is "scrappy" rather than connected in arrangement. Mention of a few of the subjects treated will give some idea of their variety. The chapters treat of such topics as White of Selborne, Snow-flakes, Birds in Mid-winter, the Great Frost of 1895, The Moon, Spring Crocuses, Catkins, Buds, Botany of a Railway Station, Midsommer Blooms, Hay-time, Love of Mountains, Reversed Spiral, &c.

For readers who are fond of natural history when presented to them in a palatable form, we can confidently recommend Professor Miall's book. They will find in it suggestions about everyday phenomena which perhaps never occurred to themselves; and, best of all, it will set them thinking on their own account. The writer's style is chatty, the language is simple when possible, and *Round the Year* may be pleasantly and profitably read in spare moments, or read aloud for the general benefit. The book has the additional advantage of being illustrated.

PURE SCIENCE IN THE BOTHY.

At the last meeting of the British Association, Professor Vines expressed his belief "that the public usually made the mistake of supposing that botany is a single science," whereas, "on the contrary, it is an aggregate of sciences, each of which it is impossible for one man to fully pursue." If this is true of botany, it is yet more applicable to horticulture and agriculture, which are arts based upon science, and that a very unskilful science. We hope our younger gardeners, while not ceasing to be practical, will lose no opportunity of basing their practice upon science, especially vegetable physiology and morphology; but if they are to be encouraged to do so, we cannot help thinking that it will be better to proceed inductively by teaching them to observe, and then cautiously to generalise from observations, rather than to adopt what is essentially a dogmatic deductive method. The study of meteorology for practical men should, we think, begin with the construction, use, and general modes of operation of weather-cock, rain gauge, thermometers and barometer, and not with the nebular hypothesis, the inextinguishability of matter and the luminiferous ether. The latter is the method adopted by M. Léon Dumas, of Illy, in the present work, which, he states, is the result of twenty years' observations "en pleine nature." We do not doubt the observations, and, to our mind, the most valuable part of the work is the tables as to the

weather in Belgium; but unfortunately the facts are buried under an excessive amount of generalisation, some of which will, we imagine, not pass muster among professed meteorologists. It may, for example, be true, as is much insisted upon by M. Dumas, that the moon has considered action on the weather, and that atmospheric tides are as important to the cultivator as those of the ocean to the boatman; but this has hardly as yet been demonstrated, nor is it within the range of practical science. Perhaps M. Dumas's work is intended for a class of highly-trained scientific cultivators that cannot be said to exist in this country, as we cannot otherwise perceive the utility of introducing at the present elementary stage of our knowledge a discussion of the Röntgen rays. The sixty-four "original" illustrations are very roughly lithographed blackboard diagrams; but then the price of the brochure is but three francs. It is divided into eight chapters, dealing respectively with our planet, the air, water, cold, heat, light, electricity, and weather forecasting, the last containing an interesting collection of French popular weather-lore rhymes. Under January appear the following:—

"En janvier pluie sans gelée
"Prépare une bonne année."
"Jour de l'an beau
"Mois d'aout chaud."
"Jours croissants
"Froids cuisants."

M. Dumas happily characterises some of these sayings as "*écrits hantés*," and others, including most forecasts extending far ahead, as "*charlatanerie*," but some are truly "the wisdom of many and the wit of one."

NOTES FROM "COFFEELAND."

PEANERS there are many who indulge in a cup of coffee who have very little knowledge of its cultivation, &c., from the seed sown to the mature bean as sold for consumption. Having lived on a coffee plantation, and also where coffee is "cured" and packed for the English markets, I thought it might interest your readers to know a little of the various processes.

The young plantation is laid out neatly and regularly in rectangular lines under "shade trees," which are most essential for the young plants' well-doing, guarding and protecting them from the stormy blast and scorching sun, and wind. The planting is done when the "monsoon bursts" in June. For the first three years the planter watches over and cares for these young plants, putting in fresh ones should any die off. The third year he is rewarded for all his labour and care by the "virgin crop," and if the "blossoming showers" which fall in April are propitious, we see a lovely sight when we get up one fine morning just like a fresh fall of snow—a vast sheet of pure white blossom, relieved by the glossy dark-green leaves, truly a sight worth seeing! The air is heavy with perfume, so strong that many people cannot endure it; but the perfume does not last long, for the flowers are very short lived, and the second day sees them discoloured and withering. When the flower falls off, you can notice small berries showing up; the rain and warm sun makes them swell and get larger and larger, till they become about the size of cherries. This takes about seven or eight months, to November, and the berries, now a bright red, are ripe. All hands are now put on to pick, women and boys are considered the best for this work, and soon the "pulp-house" is a scene of life. The day is spent in picking—more picked, more money to be earned by the labourers. At the end of the day they come trooping in, a lively chattering set, with their baskets full of the crimson fruit; this is all measured in by the "maistry," or head man, the "Avra" (master) superintending. It then goes through the process of pulping: a man takes his seat on the "cherry-loft," and through an aperture lets the berries gradually go pouring into the "pulper" below. In this way the outer red skin is taken off and thrown to one side, while the coffee runs

along wooden channels into large vats. After twenty-four hours' fermentation, it is washed, by coolies tramping and raking it, to remove the mucilage covering the bean. The "parchement," as the coffee is now called, is removed, and spread out on tables to dry. When partially dried, it is despatched in carts to the "curing-works" for final treatment. After being unloaded, it is spread out on the "barbecues" to thoroughly dry. It then goes to the "peeling-mill," to remove the dry, parchment-like skin; then it passes through the "fanmers," "sizers," and "separators." The beans are delivered into boxes showing the different sizes of "flats" and "peas" (flat and round coffee). This completes the work done by machinery. Now the coffee goes to the "garbling-room," where it is measured out to women, a bushel to each. Every bean is handled, and all that are discoloured, broken, or faulty in any way, are thrown out, and go under the name of "Triage." The coffee is now ready for packing; this is done in double sacks, each one containing 1½ cwt. nett. The bags are branded with the estate's name, also the class of coffee. This is carted or railed to the nearest coast-port for shipment to Mincing Lane, London, where it is sold by public auction. "*Peaberry, Mysore.*"

SOCIETY.

THE POTATO TERCENTENARY.

(Continued from vol. xx., p. 708.)

THE DISEASES OF POTATOES.—Continuing his remarks, PROFESSOR JOHNSON said: We must now pass on to the second part of our subject—consideration of the Potato plant in a state of disease. One well recognised physiological distinction between a green plant and a fungus is this, that a green plant can make organic substances, such as starch, out of the inorganic substances, carbonic acid and water; that a fungus, having no chlorophyll or leaf green, cannot do this, but must obtain the starch-like bodies ready-made from living animals or plants (when the fungus acts as a parasite, or from dead animals or plants, or parts of them (when the fungus acts as a saprophyte). The ordinary Potato fungus, *Phytophthora infestans*, is a parasite taking for the support of its own life the starch made by the Potato plant for itself. One of the most interesting features in Nature is the existence of the wonderful adaptation parasites, harmful as they are, slow to enable them to live their lives as successfully and effectively as independent green plants do. The Potato fungus—*Phytophthora infestans*—kills itself, so to speak, in its host, the Potato plant, in the possession of an exceedingly rich and abundant supply of food ready to hand. Accordingly, it makes the ample provision for the production of fresh generations of itself. Let us follow out the story of the fungus's life by the help of the lantern slides. In our first slide we see a Potato leaf attacked by the fungus. In such a leaf the fungus is present, and is sending delicate branching living threads in all directions through the substance of the leaf, tapping the cells of the Potato leaf of their food, and, worse still, destroying the leaf green of these cells. In our next slide we have an illustration of these fungus threads at their destructive work. In a well diseased Potato plant these threads or mycelial hyphae, as they are botanically called, run through the substance of the leaves, the pith and other parts of the haulms, down into the tubers, where they play havoc with the Potato plant's food stored there. The fungus is not content with this injury to its host. It says to itself, as it were, "the conditions here are very favourable, and as I cannot help myself more, I will arrange for more pests like myself." The fungus promptly sends out through the innumerable stomata from the under surface of the Potato leaf large numbers of delicate little threads (aerial hyphae) which branch and produce many microscopic little bodies or spore bags. Thus, on the under surface of a diseased Potato leaf there may be on a warm, wet summer's day hundreds of these spore bags.

These innumerable spore bags (conidia) are only very slightly attached when ripe, and fall off quite easily by wind or by contact with dogs, rabbits, men, or other animals moving amongst the diseased plants. When brushed off they fall either to the ground or upon other possibly healthy Potato plants, or they may be carried to these plants in the hair, &c., of the moving object. Should the air, &c., be quite dry, and continue so for some time, these spore sacs will die, and will thus not help to spread the disease. If they come into contact with water, either as rain or dew, the story may be very different. The living contents of the spore sacs usually divide into four, or more small naked bodies (the zoospores), each furnished with two very delicate whip-like cilia called cilia. When these bodies are formed, the case in which they are gets a hole in it, and out come the little moving spores. If water is present their cilia begin to move rapidly, and the little body they move swims through the water on leaf or in the soil. Soon it comes to

Physique-Météorologique, Théories Nouvelles, de la cause de l'Épandement descellules, Applications à l'agriculture, à l'Épandement, à l'Épandement, à l'Épandement, à l'Épandement. Par Léon Dumas, Professeur des Sciences à l'École normale de Illy. (Illy, 1876—80, pp. 218; 3 francs.)

SEEDS.

LONDON: Dec. 30.—Messrs. John Shaw & Sons, Seed Merchants, of Great Britain Place, Borough, London, S.E., write that, as is usual at the close of the year, there is for the moment no demand for farm seeds; nevertheless, values all round keep astonishingly firm. Full prices are asked for perennial and Italian Vicia-grasses. Sainfoin continues dear. There is no change in either Mustard or Rape-seed. Bird-seeds are neglected. Haricot Beans realise former terms. Wisconsin boiling Peas and Californian Butter-Beans show no alteration. The Linseed market is steady.

FRUIT AND VEGETABLES.

GLASGOW: December 31.—The following are the averages of the prices current during the past week:—Peas, 5d. per lb.; Apples, 1s. to 2s. per stone; Tomatoes, Guernsey, 3d. per lb.; do., Scotch, 6d. do.; Grapes, home, 1s. to 2s. do., do., foreign, 4d. to 6d. do.; Turnips, white, 2s. to 2s. 6d. per doz. bunches; do., Swedes, 1s. per cwt.; Savoy, 1s. to 1s. 3d. per dozen; Cabbages, 4d. to 8d. do.; Late do., 10d. to 1s. do.; Red do., 2s. 6d. to 3s. do.; Cauliflowers, Brynash, 2s. to 2s. 9d. per dozen; do., Dublin, 2s. to 2s. 6d. do.; Parsnips, 4s. to 4s. 6d. per cwt.; Herbs, assorted, 1s. to 2d. per bunch; Leeks, 1s. 3d. to 3s. 6d. per doz. bunches; Mint, 6d. per bunch; Onions, Dutch, 1s. per bag; do., Portugal, 1s. per stone; do., Globe, 3s. to 4s. per cwt.; Parsley, 5s. to 6s. do.; Greens, Bunch, 3d. to 4d.; Celeriac, table, 1s. to 2s. 4d. per doz.; do., common, 9d. to 1s. do.; Potatoes, best, 6d. per stone; Carrots, 2s. 6d. to 4s. 6d. per cwt.; Broccoli, 3s. per dozen; Artichokes, 10s. to 13s. per cwt.; Cucumbers, 6s. to 12s. per dozen; Lettuces, 6d. to 9d. do.; do., French, 9d. to 1s. per dozen; Horseradish, 2s. to 2s. 6d. per bunch; Mushrooms, 1s. to 1s. 3d. per lb.; Broccoli, 6d. to 7d. per dozen; Cress, 3d. per basket; Brussels Sprouts, 1s. 3d. to 1s. 9d. per stone; Endive, 1s. 6d. to 2s. per dozen.

LIVERPOOL: December 30.—Averages of the prices current at the undermentioned markets during the past week:—North Hay, Turnips, 17s. 6d. to 18s. 6d. per ton. Potatoes: Imperial, 1s. 8d. to 1s. 10d. per cwt.; Giants, 1s. 8d. to 1s. 10d.; Main Crop, 2s. to 2s. 6d. per cwt.; Champions, 1s. 10d. to 2s. do.; Whites, 2s. to 2s. 6d. do.; Turnips, 6d. to 8d. per 12 bunches; Swedes, 1s. 2d. to 1s. 4d. per cwt.; Carrots, 1d. to 8d. per 12 bunches; do., 2s. 6d. to 4s. 6d. per cwt.; Onions, English, 4s. to 4s. 6d. per cwt.; do., foreign, 2s. to 2s. 9d. do.; Parsley, 4d. to 6d. per 12 bunches; Cauliflowers, 1s. 6d. to 2s. 6d. per dozen; Cabbages, 6d. to 1s. 3d. do.; Celeriac, 8d. to 1s. 3d. do.—St. John's, Potatoes, 8d. to 10d. per peck; Grapes, English, 2s. to 3s. per lb.; do., foreign, 6d. to 8d. do.; Pines, English, 4s. to 5s. each; Mu-brooms, 1s. per pound Burkenhead.—Grapes, English, 2s. 6d. to 4s. per pound; do., foreign, 6d. to 8d. do.; Pines, foreign, 1s. 6d. to 2s. 6d. each.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending December 26, and for the corresponding period in 1895, together with the difference in the quotations. These figures are based on the Official Weekly Bulletin:—

Table with columns: Description, 1895, 1896, Difference. Rows include Wheat, Barley, Oats.

TRADE NOTICE.

MR. T. PLEDGER is shortly about to resign his appointment as gardener and bailiff to the Rev. E. W. Northey, Woodcote, Epsom, to take over a dairy and poultry farm, which has been for some years success-fully carried on by his father.

ENQUIRY.

"If this questioner much shall learn much."—BACON.

WINTER ACONITE IN PASTURE LAND.—"J. T." who possesses woodland that he is desirous of throwing into his park but which is overrun with Winter Aconite, would be glad to be informed if the foliage of this plant is injurious to stock?

WHAT OTHERS THINK OF US.—We take the following clipping from the Church Family Newspaper:—"By the way, I have been told, on good authority, that gardeners frequently ask distinguished personages to allow them to cull new plants after their names. The permission is readily given as a rule, but the custom amongst gardeners is to send a large parcel of the new plants to the noble lord or lady, with a bill amounting to something between

£15 and £20. Under these circumstances, the honour is often considered to be very dearly bought." A Church paper should, one would think, be careful not to make uncharitable assertions of this kind without substantiation. We have known a good deal about the nomenclature of plants, and been more or less concerned in it for many years, but we never heard of the "custom" that is here alleged to exist.

* * * The publication of a large number of communications is unavoidably postponed.

BOOKS: H. Anderson. The Book of the Rose, by the Rev. A. Foster-Melliar (Macmillan & Co., London). There is a work on the culture of Cyclamen, entitled, Cyclamens, and How to grow them, but we cannot say who are the publishers.—G. B. Anonim. There is no such book on the subject of parasitic plants as that you enquire about.

BOUYARDIS FOR MARKET: Bowardia. In bunches of twelve; but these must be good, or the dealers will put in twice as many sprays.

CHRYSANTHEMUMS FOR EXHIBITION: A. R. K. Your list contains many good varieties, but is remarkable for the omission of others that appear in almost every first-prize stand exhibited. You should add the following:—Madame Carnot, Mutual Friend, Australe, Vivanda Morel, Chas. Davis, E. J. Moynoux, M. Paukoczek, M. Chateau de Leché, Jno. Strimpton, Sunflower, President Barot, Mille, J. de Galbert, Thos. Wilkins, Mrs. W. H. Lees, Reine d'Angleterre, Midle. Thérise Rey, Mons. Geor. Biron, Etolde de Lyon, and M. Chas. Molin. The following from your list are not so safe:—Rita Schroeter, Pres. Armand, Mrs. Dewitt, Queen of the Buffs, Madame E. Frère, Mrs. Godfrey, R. Dean, Miss M. Bleukirin, and Miss E. Addison.

COLD STORAGE FOR GARDEN PRODUCE. Nurseryman. You should communicate with the market authorities at Leadenhall and Smithfield Markets.

DEPTH OF STOCKHOLD: Impulsion. A very small rise from the top of the boiler to the flow-pipe is needed; indeed, we have had to do with boilers which did their work well when they were fixed on the same level as the pipes in the nearest house or pit. The straighter the run and smoother the interior of the pipes, and fewer the angle-pieces and throttle-valves, the quicker the circulation. It is the ascent of the warmed water by the flow-pipe and descent of that which is cool into the boiler at the lowest point which start and keep up the circulation in the apparatus, and the easier the rise is made for the heated water, the sooner is warmth experienced in the pipes.

GRUBS, &c., IN FRUIT-SPORE PANS: G. M. G. We are unable to name the creatures, unless you send specimens enclosed in damp sand or fine mould.

NAMES OF FRUITS: H. H. 23, Easter Beurre; 27, Haysh's Bergamot; 28, Winter Nelis; 29, Vicar of Winkfield; 28, Bellissime d'Hiver.—H. H. Bewley. The fruits you send are not recognised by us—a good deal bruised.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—A. Z. 1, Abies or Picea Hudsoni of gardens; it is supposed to be an alpine form of Abies balsamea; 2, Ligustrum sinense.—C. H. W. 1, Libonia Penrothensis; 2, Lapageria rosea; 3, Cestrum (Pentstemonium) elegans; 4, cannot be named accurately without flowers; 5, Adiantum capillus-veneris; 6, Selaginella Martensii; 7, Dietyogonrauma japonica variegata; 8, Selaginella denticulata; 9, Cyrtiumum caryostatum variegata;—P. Wigton, 1, Epidendrum cochlearium; 2, Dendrobium prittuinum.—J. C. Maxillaria lepidota.—C. K. 1, Eranthemum pulchellum; 2, Ruellia nacrantha.

RATINGS: Y. In our last issue we inadvertently omitted to mention the name of the Market Gardeners, Nurserymen and Farmers' Association (Secretary, Mr. Bell, 32, King Street, Covent Garden), as having taken a leading part in the recent proceedings.

SEEDLING GRAPE FROM MUSCAT OF ALEXANDRIA AND GROS COLMAN: T. Brubshaw. Useful as a variety, but with no better flavour than Gros Colman. The berries are large, and the skin is sufficiently tough to make it a good keeper, the samples sent being plump. Being a "strong grower and free setter," it will doubtless find favour with those who are not sticklers for fine flavour in Grapes.

SHRUBS ON ROUGH GRASS-LAND THAT WILL NOT BE EATEN BY SHEEP: C. E. Common Juniper, Thuus in variety, including the Blackthorn; Cypressus Noctonensis alba; Thuus vulgaris, the common Berberis, also B. aquifolium, clumps of Rhododendron ponticum, if the soil is not unsuitable, and you can fence them off with iron-hurdles, the leaves having somewhat powerful effects on some animals when eaten; the same holds good of the Common Laurel, if planted on pasture-land. Common Spruce and Scots Fir, which can be kept at any desired height by topping the leader make capital pheasant coverts.

STRAWBERRIES FOR MARKET.—Royal Sovereign, Sir Joseph Paxton, British Queen, Elton Pie, Earliest of All, Waterloo. The first four of good flavour, and the others early and prolific.

WIRE SUPPORTS FOR PEAS AND BEANS: H. S. As articles offering advantages to amateur cultivators residing in suburban districts, and those in which copes and woods are scarce, these wire supports are likely, if reasonable in price, to supply a want; but in large gardens in woodland districts, and in market gardens anywhere, owing to fast cost in the latter case, and the usually abundant supply of material in the former, they are less likely to be in demand.

GARDENING APPOINTMENTS.

Mr. A. L. KNIGHT, late of Albury Hill, Herts, as Head Gardener and Bailiff to H. BOLAND BROWN, Esq., Orchard Grove, Harrow Weald, Middlesex. Mr. G. CHILCOTT, for the past seven years the Orchard Gardener, Park Place Gardens, Henley-on-Thames, as Head Gardener, C. BENSKIS, Esq., Glenhorn, Harrow Weald, Middlesex. Mr. ALFRED WRIGHT, for a period of about fourteen years in the gardens, Bocking Place, Brintree, as Head Gardener to J. G. DEARDE, Esq., Walnut Hill, Stamford, Lincolnshire.

CATALOGUES RECEIVED.

KELWAY & SON, Langport, Somerset.—Wholesale List of Seeds. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea.—(1) Seeds and Implements; (2) Chrysanthemums, LITTLE & BALLANTYNE, Carlisle.—Seeds, &c. T. MEYER & SONS, 15, Prince's Street, Edinburgh.—Seed, &c. E. P. DRON & SONS, Hull.—Seeds, &c. H. J. JONES, Ryecroft Nursery.—Hither Green, Lewisham.—Chrysanthemums. BROWN & WILSON, 10, Market Place, Manchester.—Seeds. MOSEY, 1, Rue Saint Symphonien, Versailles.—General Nurseries, Stock. DICKSON, BROWN & TAIT, 4; and 45, Corporation Street, Manchester.—Seeds and Garden Requisites. DICKSON & HEDDISON, 12, Old Millgate, Manchester.—Seeds, &c. H. CANNELL & SONS, Swanley, Kent.—Chrysanthemums.

CONTINUED INCREASE IN THE CIRCULATION OF THE "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has since the reduction in the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among country gentlemen, and all classes of gardeners and garden lovers at home, that it has a specially large foreign and colonial circulation, and that it is prepared for reference in all the principal libraries.

THE

Gardeners' Chronicle.

SATURDAY, JANUARY 9, 1897.

SIR JOSEPH BANKS.*

OF the many thousands, or perhaps one might say millions, of persons who have read the narrative of Cook's first voyage, few knew that it was a compilation, by an outsider, from the journals of various members of the expedition. This was so, however; and not till a century and a quarter had elapsed did the immortal navigator's own journal become accessible to the British public. In 1893, Rear-Admiral (then Captain) W. J. L. Wharton, Hydrographer of the Admiralty, edited Cook's journal, with annotations and a sketch of his life. Sir Joseph Hooker, who visited many of the same countries, with the same object, some seventy years later, has now given us Sir Joseph Banks's journal of that memorable voyage, in which he took part in the capacity of naturalist; and he it said, wholly at his own expense. Banks was a liberal promoter and patron of botany and horticulture, one of the original members of Council of the Horticultural Society of London, and the pioneer of botanical exploration in the southern hemisphere, so that some particulars of his share in the discoveries may be acceptable to readers of the *Gardeners' Chronicle*.

Cook's first voyage was accomplished in a bark of 370 tons, which left England with no fewer than ninety-four persons on board, and a small armament. The chief objects of the voyage were to observe a transit of Venus, and to discover new countries; both of which objects were highly successful. Otaite (Tahiti), in the Society Islands, was Cook's destination to observe the transit. When Mr. Joseph Banks became aware of the intentions of the government, he applied to his friend, Lord Sandwich, then at the head of the Admiralty, for permission to join the expedition, and there is no doubt that the success and scientific results were largely due to his knowledge and indefatigable exertions. Banks was a wealthy man, and thus able to engage a competent staff of assistants and servants, and equip them thoroughly. His staff consisted of Dr. C. D. Solander, naturalist; J. Reynolds, S. Parkinson, and A. Buchan, artists; H. Sporing, clerk; J. Roberts, P. Briscoe, T. Richmond, and G. Dollin, servants, the two last, negroes. Those who know of the excessive hardships, privations and sickness attendant on long voyages in those days, will realise something of the character of Banks; and when we know that only three out of his staff of nine survived the voyage of less than three years' duration, we become more fully impressed with the serious nature of the undertaking, and the

sacrifice of ease and comfort made by those who voluntarily took part in it. The expedition left Plymouth in August, 1768, and after spending five days at Madeira, proceeded to Rio Janeiro, where it met with a hostile reception, not being permitted to land, though some of the gentlemen, Banks among others, did so clandestinely. Thus Banks had to lament the loss of an opportunity to collect in this marvellously rich tropical vegetation. From England outward they had employed their time in fishing, dredging, and shooting, and in the preparation, description, and naming of the specimens of animal and vegetable organisms thus obtained; yet few, if any, of them were ever published by the authors.

Botanising did not begin seriously till they reached Tierra del Fuego. Here they landed on Staten Island several times, and collected a number of plants, "all of which were new." A party of twelve, headed by Banks, attempted an excursion into the interior; but the difficulties they encountered were beyond all anticipations, and they were benighted, with disastrous results. The cold was intense, and they were wholly unprepared to pass the night in the open. What was worse, nearly all the members of the party were seized with almost unconquerable drowsiness, the effects of the extreme cold to which they were exposed. Had it not been for Banks's vigorous constitution and unremitting efforts, it is probable that the whole party would have perished. As it was, his two black servants were frozen to death, and several others only escaped the same fate through the persistence of their companions; even Dr. Solander could not be prevented from lying down in the snow to sleep. Eventually a fire was kindled, to which the weaker members were literally dragged by the stronger ones. All they had to eat was a vulture, killed on the way. This was skinned and divided in ten portions of about three mouthfuls each! During the night and far into the day there was a blinding snow, yet they reached the shore, though in a very exhausted condition, by 1 o'clock, having been more fortunate in their choice of road on their return than in going out. Subsequently further collections of plants were made, yet, strange to say, it fell to the lot of Sir Joseph Hooker to publish many of them more than half a century later in his *Flora Antarctica*. Banks specially mentions the antiscorbutic plants, which were of great importance to them with their very limited dietary. The Beeches, too, attracted their attention, but one of them was mistaken for a Birch, even by the botanists, so that the colonists of New Zealand may be excused for calling their Beeches Birches. At the end of this part of the journal is a list of 101 phanerogamic and 41 cryptogamic plants collected in the region, but Sir Joseph Hooker has not reproduced it.

From Staten Island they sailed round Cape Horn away to Tahiti. This occupied nearly three months, and Banks recounts how they had successfully combated the dreaded scurvy by a liberal allowance of sauerkraut, pickled Cabbage, and Lime-juice. Four months were spent in the Society Islands, where our voyagers had, on the whole, a very agreeable time; and various interesting discoveries were made, but many of the rare and peculiar plants of the mountain valleys escaped their notice. Thence they sailed westward to New Zealand, making land in what Cook named Poverty Bay, in October, 1769. Although Cook was not the actual discoverer of New Zealand, it was practically unknown before, and on this occasion he circumnavigated the islands, spending six months in the operation. The naturalists, of course, were very busy; but although they landed in many places, they could not penetrate far into the interior. In spite of this drawback, they obtained 360 species of flowering plants and Ferns, almost all unknown to science. Most of the plants were drawn by Sydney Parkinson on the spot, and his drawings were engraved on copper after the return of the expedition to England. Dr. Solander drew up descriptions of the plants, but neither descriptions nor plates were ever published. A few of Solander's

names were taken up by other writers; but otherwise the many thousands of plants spent by Banks were unfruitful, and most of their work was anticipated by Richard in his *Flora de La Nouvelle Zelande*, published in 1832.

Among the plants discovered in New Zealand was the handsome *Clianthus puniceus*, which was collected in Mercury Bay. It appears to have been rare in a wild state, even in those days, and now it is exceedingly rare, being confined to one or two small islands in the Merimiri river. They also discovered the only *Palu*, *Areca sapida*, native of New Zealand, and greatly enjoyed its "cabbage," or crown of undeveloped leaves. But what more impressed them was the variety and size of the trees, especially the Conifers, such as the *Kauri Pine*, *Dammara australis*, and *Podocarpus dactyloides*. *Knightsia excelsa*, one of the two Proteaceæ that inhabit New Zealand, was "among the stately trees that particularly attracted the attention of our indefatigable naturalists." Banks mentions a tree of *Podocarpus dactyloides*, which girthed 19 feet 8 inches at 6 feet above the ground, and measured 89 feet to the first branch, tapering so little that Cook estimated that it contained 350 cubic feet of solid timber clear of the branches. In this connection I may add that Sir Joseph Hooker followed Banks in New Zealand some seventy years later, and made large collections of dried plants, which, with those made by Banks and Solander, formed the basis of his large illustrated *Flora*.

When Sir Joseph Hooker was there (in 1841 colonisation had hardly begun; now, fifty-five years later, the country is covered with farmsteads, which supply the Old Country with mutton, and dotted with ports and towns, numbering thousands of inhabitants.

On March 31 they left New Zealand, sailing north westward until they discovered the east coast of Australia, where they first landed in a bay, which they afterwards named Botany Bay, on April 28. With the exception of less than a dozen plants brought home in 1799 by Dampier (including, curiously enough, the only other species of *Clianthus*—*C. Dampieri*), absolutely nothing was known of the flora of Australia, so that here again Banks and Solander had a new field, and indeed not on a new field, but a flora so different from that of any other part of the world, as to cause astonishment and surprise. The first tree that attracted Banks's attention was a large one, a species of *Eucalyptus*, yielding a gum much like *gamboge dracena*. Subsequently several species were discovered, and Banks was correct in his conjecture that they belonged to the same genus as the gum tree described by Dampier. Banks also states that they met with vast numbers of a plant yielding a yellow gum, which from his description was evidently *Xanthorrhoea*, now called Grass-gum trees. Several myrteophilous plants were observed, including a species of *Myrsine*—*Myrsine*—*Myrsine*; and it was noticed that the fruit of a fig contained a number of species of *Cynips*, very like, if not exactly the same as *Cynips syconiorum* of Linnaeus. Two different *Palus* were met with, and the "cabbage" of both was used as a vegetable.

After leaving Botany Bay, they sailed northward, and narrowly escaped the total loss of their ship, which struck and grounded on a coral rock, which soon cut a hole in her bottom. Favoured by good weather and a numerous and willing crew, they succeeded in getting her into a river, where they repaired her. This was named after the ship, Endeavour River, which name it still bears. On this coast Banks found a great variety of drift seeds and fruits, including a number of cocoanuts, which had been opened by a kind of crab. He does not mention having observed any *Coccoloba* tree on this coast, and Sir Joseph Hooker remarks in a foot note, "that the absence of this *Palu* on the coasts of Australia is one of the most singular facts in botanical geography." But although there is no doubt that it is exceedingly rare on this coast, it is recorded by Bentham (*Flora Australasica*) from Koppel and Rookingham Bays, distant localities; and Mueller (*Conspectus Australiæ*) includes it as a native of Queensland. *H. Botting* (*Hort.*), (to be continued)

* *Journal of the Right Hon. Sir Joseph Banks*, during Captain Cook's First Voyage in H.M.S. *Endeavour*, in 1769, to Tierra del Fuego, Otaite, New Zealand, Australia, &c. Edited by Sir Joseph D. Hooker.

NEW OR NOTEWORTHY PLANTS.

PLANTS FROM ASIA MINOR.

Erantlis cilicica.—*Erantlis hienalis* is already well known as one of the earliest of spring-flowering plants. *Erantlis cilicica* is, however, much larger, and more beautiful. It is invaluable when planted in chalky loam among rocks and wood chips. Fifteen to twenty tubers planted in 4-inch pots can be easily forced in a cool-house, and will bloom freely in February.

Galbanus Foderi.—If bulbs of this species be planted in pots early in August, they will be ready to bloom in a cool-house at the beginning of November. This plant also prefers a chalky soil.

Sternbergia macrantha.—The well-known *Sternbergia lutea* is a graceful bulbous plant, which blooms in November or December. There was a plant about to flower in the open ground in the Berlin Botanic Garden on November 17, 1896. *Sternbergia macrantha* is also worthy of note. The sweet-smelling flowers, of a luminous yellow colour, are about 4 inches in diameter, and appear in October. The cut blooms remain fresh in water from three to four days.

Fritillaria aurea is a very pretty species, only 1 inches high, with golden yellow flowers spotted with reddish-purple. It grows in luma-rich loam.

Fritillaria Boronaefferi is larger than *Fritillaria aurea*, and has larger golden-yellow flowers checked with reddish-purple.

Fritillaria Libanatica is a very beautiful species, resembling *Fritillaria paucicaulis*.

Fritillaria Stebania, Haussknecht (?), n. sp.—A very splendid new species, more than 1½ foot in height, with large flowers. It flourishes on chalky soil with leaf-mould (luma). The bracts (perianth-leaves) are bright green outside, streaked with reddish-purple, yellowish inside, and also marked with purple.

Iris Danfordiae.—True specimens of this small yellow-flowered Iris, which has been figured in the *Botanical Magazine*, are very rarely found in the trade. Its importation is therefore particularly to be welcomed. This is also the case with the handsome Iris *Fuoncia*. This tall species resembles *Iris florentina*. It has very large, pale blue flowers; the outer segments are of a rich deep blue-violet, veined with dark brown. The flowers have a delicate perfume. *The Botanical Gazette* (Chicago, Ill.), November, 1896.

NOVELTIES OF 1896.

(Continued from p. 2.)

ORCHIDS.

NURSERMEN.—MESSRS. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, maintain their place as *facile principes* among raisers of hybrid Orchids, and had the record of their year's work been solely the production of the charming white *Lælio-Cattleya* × *Decia* alba, the generally-admitted best hybrid Orchid of 1896, and the noble L. C. *Rosalind* (Triana? Domini?) (*Gard. Chron.*, Jan. 2, fig. 1), for which they received a First-class Certificate at last meeting of the year, and which is a close second-best of the season, much would have been accomplished. But pursuing the consistent course which they have always adopted, Messrs. Veitch have brought out other fine winter-flowering hybrids, some of the L. Perrini crosses, so well represented by their beautiful *Lælio-Cattleya* × *Laly* Rothschild, having proved great favourites. Among the best for which this firm have received certificates during 1896 are *Lælio-Cattleya* × *Doris* var. *Nautila*, an almost entirely orange-yellow flower; L. C. *Tiresias* (C. Bowringiana × L. C. elegans), L. C. *Nysa* superba, a great advance on L. C. *exoniensis*; *Cattleya* × *Apollo* (Mossie? A. Khande?), of an entirely new section of hybrids; *Cattleya* *Atlanti*, a noble plant, which has been previously shown, but only certified as First-class last year; C. × *Elvina* (Triana? Schilleriana), and C. × *Euphrasia* (Warszewicz? superba?), both very distinct novelties. Out of their importation of *Cattleya Schroederae*, Messrs. Veitch flowered three very fine new forms, viz., C. *Schroederae* *arcuiflora*, C. S. *eximia*, and

C. S. *caloglossa*; and continuing the crossing of *Epidendrum Wallisii*, they evolved the beautiful E. × *Edresio-Wallisii* superbum, and E. × *elegantulum* (Wallisii? × *Enfresio-Wallisii*), both charming, compact, and floriferous kinds. Of their new *Cypripedium*, C. × *Baron Schroder* (*omanthum superbum* × *Fairieanum*) is by far the best, and will be difficult to surpass in its section; C. × *Regina* (× *Læcanum* × *Fairieanum*), a fine representation of the C. × *Arthurianum* class; C. × *Euryades* (× *Læcanum* × *Boxalli*), handsome and very variable, one form certificated having a heavily blotched white dorsal sepal, while the other had the same feature of a purplish-chocolate, with white tip. *Selenipedium* × *Schroedera* var. *candidum*, is a fine white form tinged with light rose. *Masdevallia* Ajax (M. Chelson × M. Peristeria), a worthy production, with rich red, yellow, and brown flowers. *Phaiocalanthe* × *Seleni* albiflora, deemed worthy of a First-class Certificate; and *Clysis* × *Langleyensis* (× C. Chelson × C. bractescens), a fine white flower, with the segments tipped with rose, like a large form of C. *Linnæi* (fig.).

Messrs. F. SANDER & CO. excel in hybrid *Cypripediums*, and from their stove-houses at St. Albans, among other novelties which flowered in 1896, come C. *Minnie Ames* (Curtisii × concolor), C. *Henri van der Straeten* (× Mrs. C. Canham × *Læcanum*), C. A. R. Smith (callosum × *Druryi*), C. *Rothwellianum* (Argus × Stonei), C. *Fairy Queen* (Curtisii × *Druryi*), C. *McNabianum* (callosum × concolor), C. *Neptune* (lo grande × *Rothschildianum*), C. *Lathamianum* albescens (Spicerianum magnificum × villosum aureum), C. *Grovesianum* (Lathamianum × *Læcanum*), C. *Lady Winborne* (villosum × *Læcanum* giganteum), C. *Mrs. C. Maynard* (mites var. × *Boxalli*, C. *Satura* (villosum × *Læcanum* *Marsceleanum*), C. *excelesior* var. *Mars* (Harrisianum × *Rothschildianum*), and *Selenipodium Uranus* (Lindleyanum × grande).

Of other hybrids remarkable are *Calanthe Novelty* (veratrifolia × *Cooksoni*), the first break between the evergreen and the deciduous species. *Dendrobium Curtisii* × *Cassiope* × *aureum*); *Phaius* *Ashworthianus* (Munoi × *manulatus*), and *Lælio-Cattleya* *Mardi* var. *Fascinator*.

Of imported species and varieties the *Lælia purpurata* "Distinction," L. p. albo-violaceum; *Cattleya* *Mossae* "Her Majesty," C. *Mondell* "Countess of Derby," and *Miltonia* *veixillaria leucoglossa*, which secured awards at the last great show at Manchester, are all superb flowers; and *Mormodes badium* and *Bulbophyllum Ericssonii*, flowered for the first time in 1896, showing them to be remarkable introductions. Other good novelties of Messrs. F. Sander & Co. are *Spathoglottis plicata* *Nicholitzii*, *Sobralia Brandtiae*, *Cattleya Percivaliana amœna*, *Oncidium Godseffianum*, *Cattleya labiata* *The Pearl*, C. I. *The Bride*, C. I. *Puritan*, and C. I. *Baron Schroder*, all nearly white varieties. During the year also the firm have reintroduced *Cypripedium Mastersianum*, *Angulosa uiflora* var. *Turneri*, *Maxillaria striata*, and imported number of pretty botanical species.

Messrs. HUGH LOW & CO. have to their credit the phenomenal *Cypripedium* *Charlesworthii* *Lowii*, the finest *Charlesworthii* yet seen; the magnificent *Cattleya* *Mossie Anolliana*, *Low's* var., which secured one of the four First-class Certificates awarded at the last Temple Show; the scarcely less beautiful *Odontoglossum crispum* *Lowie*, exhibited on the same occasion; and the richly-coloured *Cattleya Mossie Brilliance*.

Of continental productions, MESSRS. LINDEN, l' Horticulture Internationale, Parc Leopold, Brussels, take the lead with *Cattleya* *The Czar*, the best natural hybrid imported during the year; *Odontoglossum crispum* var. *augustum*, a noble flower, which was so much admired, and gained a First-class Certificate at the last great Temple show (*Gard. Chron.*, May 28, p. 649). From their fine importations of *Odontoglossums* also some very handsome natural hybrids, indicating new ground, have been exhibited both at Brussels and London, and many of them figured in the *Lindensia*. Of them the best were O. *crispum* var. *melegris*, O. c. *citratum*, O. c. *Colos*, O. c. *spectabile*, O.

rubiginosum, O. × *Trojanowskyanum*, O. × *Wilckeanum* var. *rufum*, O. × W. var. *olivare*, O. × W. var. *elongatam*, and O. × W. var. *fascium*. Attempt has been made to classify these singular and handsome variations, some of which range closely to O. × *excellent*, but have features differing from the ordinary types. Messrs. Linden also produced in 1896 the handsome *Lælio-Cattleya* × *Wargnyana*, L. C. × *Schulzeana*, *Cattleya* × *Methoë*, and a number of splendid and distinct varieties of *Cattleya Mossie*, *Catasetum* × *splendens*, and other things which are duly illustrated in the *Lindensia*; also *Acanthophippium Mauritii*, *Cypripedium Lebanyanum*, *Cyclopogon lurida*, and many others of considerable interest.

Mr. PEETERS, of Brussels, at the meeting of the Royal Horticultural Society on March 10, 1896, brought before the notice of the Orchid Committee the fine hybrid *Zygopetalum Perrenoudii*, and *Miltonia Blouana aurea*, both of which secured awards.

M. JULES HYE-LEYSER, of Ghent, that adept at Orchid culture, staged at the Temple Show the large and handsome *Miltonia vexillaria* *Coccani*, and some good *Odontoglossums*. M. P. WALTER, of Magdeburg, Wilhelm-tal, flowered the new white *Acanthophippium eburneum*; M. ZOLLINGER-JENNY, of Zurich, the remarkable *Dendrobium Jenuyanum*; M. MANOS, gardener to M. Fourrier, of Marseilles, *Lælio-Cattleya* × *velutino-elegans*, and other worthy hybrids; M. BABYER, of Geneva, *Epidendrum* *Barbeyi* and *Saccolabium Barbeyi*; and 1 others also have also contributed.

From this hurried review it will be seen that although the gains in Orchids to gardeners during the past year have been satisfactory, the result has been secured by the patient productions of small quantities of good things rather than by large importations.

Among the new or rare Orchids illustrated in the *Gardeners' Chronicle* in 1896, are *Angulosa uiflora* var. *Turneri*, April 4, p. 423; *Cattleya* *Le Czar*, Nov. 14, p. 539; *Dendrobium Arachnites*, July 4, p. 7; *D.ymbidoides*, May 9, p. 581; *D. x Wigianum*, May 2, p. 553; *Disa pulchra*, Dec. 26, p. 785; *Epidendrum* × *elegantulum*, March 21, p. 361; *Houlletia Lowiana*, Dec. 12, p. 716; *Lælia purpurata* var. *Ashworthiana*, July 11, p. 39; *Masdevallia* × *Shuttryanii*, *Chamberlainii* var. *Feb.* 29, p. 262; *Maxillaria striata*, Nov. 21, p. 631; *Odontoglossum crispum* *augustum*, May 23, p. 649; O. c. *Ashworthianum*, Feb. 15, p. 197; *Sophro-Cattleya* × *Calypso*, Dec. 5, p. 695; *Zygopetalum* × *Perrenoudii*, March 21, p. 367.

STOVE AND GREENHOUSE PLANTS.

As usual, when reviewing the gains to gardens during the past year, the events which most readily present themselves to the mind, and which were at the time considered the most interesting, are connected with well-known plants flowering for the first time, and with re-introductions. Such were the two remarkable examples of the long-looked-for *Caneosia maxima* in certain gardens in 1896. A flowering spray, and details of a flower being given, together with remarks on the unique occurrence, in these pages on Nov. 14, p. 596, and other issues. The florists' *Primula* of Messrs. Sutton & Sons, Cunnell & Sons, Carter & Co., and other great raisers, seem to have attained the highest point of excellence as florists' flowers, and the introduction of the true species will afford an opportunity to hybridists to commence, *de novo*, on other lines than those which florists are apt to mostly affect, a start having been already made by Mr. Hyde by crossing *P. smensis* and *P. obconica*, and raising the seedlings and flowering them. What Messrs. Sutton have been able to effect is not yet made public.

Sir Trevor Lawrence, Bart., who takes an especial interest in raising new *Anthuriums*, exhibited a godly number of varieties at the meetings of the Royal Horticultural Society early in the year, the best of those which received awards being A. *Lawrenceana*, the finest large white; A. *Rothschildianum* elegans, rose-coloured, spotted and flaked with scarlet; A. *Rothschildianum maximum*, a noble spathe with white ground, spotted and marbled with crimson;

and *A. pumilum*, a dwarf and profuse variety with scarlet spathes, splashed with crimson. Other good flowers of this class from Burford were *Bertoulia Leopold II.*, a profuse bloomer, and with very pretty leaves; *Begonia odorata rosea* and *Canna Roi des Rouges*, both of which may be available as decorative plants in the summer flower-garden.

Messrs. Jas. Veitch & Sons, of the Royal Exotic

of a very pretty species, hitherto very rare, figured in *Gardeners' Chronicle*, October 3, 1896, p. 393. In their fine exhibit of about 180 kinds of Cacti at the Temple Show, some handsome, distinct, and charmingly tinted *Phyllocacti* were selected for awards, viz. *P. Ena*, *P. Ovis*, *P. clatior*, *P. Eurasian*, and *P. Venus*; and on the same occasion, among their Certificated *Caladiums*, were *C. Silver Cloud*, silvery-

scarlet flowers; *R. Cloth of Gold*, a fine pale yellow, and *R. nobiliss.*, clear fawn-yellow, are new and distinct. The *Streptocarpus* have been improved by new crosses, and these favorite flowers are fast settling down among florists' flowers of the herbaceous class, and they are far easier to grow and more remunerative in the matter of bloom than most of such plants. Other novelties Certificated to Messrs. Veitch are *Begonia Prince Charles* of Denmark, a lovely foliage of the Rex class; *E. Essigii*, a valuable double winter-flowering kind. *Platyceium Veitchii*, a fine and distinct stag-horn Fern; *Polygodium Schneideri*, which received a First-class Certificate, and is one of the most remarkable of hybrid Ferns; and *Pteris Boltoni* and *Polygodium nerifolium cristatum*, both fine decorative kinds.

POLYGONUM BALDSCHU-
ANICUM.

On September 13, 1891, the Société Nationale d'Horticulture de France allotted a First-class Award to this plant, when the following description of it was published: "*Polygonum Baldschuanicum* grows wild in Turkestan (eastern Bokhara), at an altitude of 3,000 to 5,525 feet, and where it was discovered in 1882 by M. Regel, fils. At first known as *Atriplexis* sp. nova, it received its present name and was described and figured by E. L. Regel in 1883. It is a herbaceous species, the stem, woody at the base, is robust, and attains a height of 13 to 16 feet. The leaves are a beautiful green, cordiform or hastate, the flowers white, faintly rosy, forming long handsome trusses; they are succeeded by winged fruits, white at first, then red, and themselves decorative. The plant seems hardy in Paris, for if the stems die in winter, fresh shoots are sent up in the spring." M. V. Lemoine of Nancy, who sends us the photograph (fig. 1), has grown this plant for two years, and is well satisfied with it. In two months a medium sized plant grew 10 or 13 feet high; the stems are twining, attaching themselves to any handy support; flowering commences in June and lasts until September. All the ramifications of the stem form close panicles, sometimes erect, sometimes horizontal, sometimes recumbent; they give an appearance as of wreaths supported on a trellis formed by the plant. M. Lemoine set the plant at the foot of a dead Elm tree, it soon reached the lower branches, covering them all the summer with a multitude of white flowers, very beautiful and effective. The flowers are very useful for cutting, and the plant itself is hardy.

THE GLADIOLUS.

I was interested in reading Mr. Krelage's remarks at p. 701 of the last volume on the more recent hybrids of Gladioli. After the *G. gandavensis* hybrids, the most beautiful seem to be those of the *G. Lemoinei* section, and as *G. Nanceianus* are from Mons, Lemoine, that gentleman may be congratulated on the result of his work in this direction. For years I have urged the importance of amateurs taking up the culture of the various species of Gladioli, and hybridising them in various ways. What is chiefly required for their culture is a light sandy loam. Dean Herbert gives a very interesting account of his successes and failures in his book on *Bulbs*, published by Ridgway & Sons, Piccadilly, in 1837. This includes a paper on what he terms "Cross-bred Vegetables, or crosses and hybrid intermixtures in vegetables." We have learned much since Herbert's time, and as it came out in the year the Queen began to reign, we have in the *Amaryllidaceæ* a starting-point for any one who would endeavour to trace the history of such a genus as the Gladioli during a period of sixty years. Gaertner had tried, and as he thought, successfully to obtain bi-generic males of various plants, and up to that time, as Herbert states, none had been obtained. He says, "The fact is that in this country, where the passion for horticulture is great, and the attempts to produce hybrid intermixtures have been very extensive during the last fifteen years, not one truly bi-generic male has been seen, and although I in no means presume to assert that such a production is

FIG. 1.—POLYGONUM BALDSCHUANICUM; HARDY PERENNIAL CLIMBER; FLOWERS WHITE.

Nursery, King's Road, Chelsea, gave evidence of unabated energy in every branch of their extensive plant nursery. Of their new introductions, *Bidymocarpus malayanus* is a dwarf species, pretty in leaf and flower; *Aglaonema longifolium* var. *Curtisii*, is a pretty hot-house plant with leaves of a light green colour with silvery spots; *Maranta major*, a strong-growing species, of great usefulness as a decorative plant for apartments, &c.; and *Acidantha bicolor*, a new introduction

white, spotted with green, and with crimson veining; *C. Duchess of Cornwall*, white, tinged with emerald-green, and flushed with rose; and *C. Sir Julian Goldsmid*, a dwarf kind, red with crimson veining. Of the famed Veitchian strain of *Amaryllis*, *A. Eros*, and *A. Rosalind*, two superb light-coloured kinds, and *A. Myra* and *A. Ercles*, two brilliant orange-scarlets, have been adjudged the best. Of the *Rhodolendrons*, *R. Little Beauty* (*Monarch malayanus*), a neat plant, with glowing crimson-

impossible, experience shows it to be improbable, and those (referring to Gaertner's experiments) who fancy they have obtained one, must forgive my wishing to see it forthcoming, and to examine whether it is certainly of such descent as they suppose."

Returning to the subject of this paper, Mr. Krelage states that Herbert and others had freely crossed *G. psittacinus* and *G. oppositiflorus*. I do not know what others have done, but Herbert does not say in his book that he crossed *G. oppositiflorus*. He describes *G. oppositiflorus* in vol. v., see on-1 series of *Bot. Key*, as being a native of Madagascar, where it had been found by Forbes, and states that the *G. gaudavensis* of gardens is a cross between *G. oppositiflorus* and *G. natalensis*. In a later paper communicated to the Horticultural Society in October, 1846, and published in 1847, Herbert again alludes to these crosses. He says *G. cardinalis* and *G. natalensis* refuse to mix with each other, but do so freely with *G. oppositiflorus*: but in neither place does he make any allusion to having effected the cross himself.

The true plant has flowered at Kew, and is well figured in the *Botanical Magazine*, t. 7292. If Van Houtte's statement cannot be taken as correct, there may also be some doubt about Herbert's, as he does not seem to have verified them. The plant figured in May, 1893, *Botanical Magazine*, t. 7292, seems to be just such a plant as we might expect *G. gaudavensis* to be before it was taken in hand by the florist; and all the beautiful varieties raised in England and France might have been so produced by ordinary generation and good culture, selecting the best varieties year after year as we know has been done in the case of the Chinese *Primula* and some other garden-plants. Some of the more beautiful species of this genus had been introduced before 1837, but in that year a very handsome new variety flowered with Messrs. Rollison, *G. Mortouini*, the flowers of good form and beautifully marked with pale-rose or pink on a white ground (*Botanical Magazine*, t. 3650).

In 1842, the following were described by Herbert in the *Botanical Register*: *G. crispiflorus* (81), *G. caucasicus* (82), *G. aquinoctialis* (97). This he adds exists at Spofforth, but it had not flowered; it was from Sierra Leone, and the only known tropical *Gladiolus*. Dr. Lindley had a dried specimen in his herbarium, *G. oppositiflorus* (98), as described above. In 1843, *G. splendens* (61), a garden variety, is described; and in 1844, *G. festinus* (87), a Cape species which flowered at Kew. There are no species of *Gladiolus* figured in the *Botanical Magazine* from 1838 until 1861. Previous to that year, Mr. Saunders sent a collector to Cape Colony, a Mr. Cooper, who amongst other productions, sent numerous species of *Gladioli*, and as a result *G. sericeo-villosus* was figured in *Botanical Magazine*, t. 5427. The plant grew to a height of about 1 feet, producing a long densely-flowered spike of yellow flowers, the stem and spathe thickly clothed with shaggy silky hairs; it is a very remarkable and distinct species. Following this came other distinct and beautiful forms from the liberality of the late Mr. W. Wilson Saunders, and the industry of his collector, Cooper.

In 1866 *G. papilio* was figured, t. 5565, and well described as follows:—"Nothing can well exceed the delicacy of the pale purple of the upper petals, or the vividness of the deep purple and golden-yellow markings of the lower ones."

In 1869 the gorgeous *G. erematus* was figured, t. 5810; it was engraved from a specimen flowered by Mr. W. Bull in his nursery at Chelsea; and was well described by the late Mr. Thomas Moore in the *Gardeners' Chronicle*, 1868, p. 1139, and although this species is not mentioned by Mr. Krelage in his paper, it has been the primal source of many fine garden varieties. Sir J. D. Hooker says, "The original plants that have hitherto flowered are made over to be hybridised, so that in all probability the pure race will soon be lost to cultivators." The next in order, 1870, is *G. Saundersii*, t. 5873, and although this "a much more handsome plant than *G. psittacinus*, remarkable for the vivid colour of the curiously deformed and very broad perianth." It was detected and sent home by Cooper. In 1871 the very remark-

able dingy-coloured species *G. dracocephalus* was figured, t. 5884. "The lurid hues of its flowers are wholly unlike those of any of its congeners." This was also found by Cooper.

In 1872 we have *G. purpureo-auratus*, t. 5944. This was also imported and flowered by Mr. W. Bull at Chelsea, and is one of the parents used so successfully by M. Lemoine. The sepals and petals of this species are pale yellow, heavily blotched with purple. The next species figured in the *Botanical Magazine* was in 1875, *G. Cooperi*; as its name implies, it is one of the more remarkable introductions of Mr. Wm. Cooper, and the editor remarks on this and others introduced by him, that he has "enlarged materially the groundwork upon which hybridisers can carry forward their experiments."

In 1877 two species are figured, *G. ochroleucus*, t. 6291, introduced by Mr. W. Bull from the Traasval, and the truly distinct and pretty species *G. Eckloni*, t. 6335, sent over by Cooper, and first flowered by Mr. Elwes at Cirencester. The flowers are small, well formed, and densely spotted of a red-purple colour on a pale ground.

In 1879, *G. brachyandrus* was figured, t. 6463; it is a native of Zambesiand, and was first sent to the Edinburgh Botanical Gardens, and flowered by Mr. Sadler. The perianth is upright and of a pale scarlet colour. In 1881 another of the species from tropical Africa was figured, *G. Quartianus*, t. 6739. It was gathered in Abyssinia by W. Quentin Dillou, and by Sir John Kirk in the Zambesi country. The flowers are yellow, flushed and spotted with scarlet. Mr. Baker says, "it certainly has a claim to take rank amongst the finest species of this beautiful genus." In 1885 *G. Kotschyanus* was figured, t. 6897. This is a truly remarkable species, a native of Persia and Afghanistan. Mr. Baker says, "it is the first fruits from a horticultural point of view, of Dr. Aitchison's labours as botanist to the Afghan Boundary Commission." The flower-stems are slender, stiffly erect, furnished with small bright lilac-purple flowers.

In 1887 there is a figure of *G. Watsonioides*, t. 6919; it was found on Mount Kiamranjaro, by Messrs. Thomson and Johnston. The flowers are scarlet, thinly placed on a somewhat slender stem. The only other figure is one of *G. oppositiflorus* in 1893. The first quarter of a century there was no species introduced, and but for the enterprise of a private individual the period would have been longer; but if anyone will turn up and examine the coloured plates, which I have pointed out, they will see how ample is the material with which the hybridist has now to deal as compared with that to which Dean Herbert had access in 1837, when his exhaustive book was passing through the press. Herbert grew all his plants hardy, and the hybrids, he says, did "well in the natural soil, which is a good yellowish light loam, suitable for Birley; and also in the artificial borders of peat and sand." His hardy crosses were between *G. cardinalis*, *blanckis*, *carneus*, *inflatus*, *angustus*, and *tristis*; and they varied with every shade of colour, from white to scarlet, rose, coppery, and blackish-purple, and some are exquisitely speckled in consequence of the cross with *tristis*. As the worthy Dean's experience of open-air culture was most successful, I will give it in his own words: "They succeed best when grown into a thick tuft, in which state the profusion of bloom is admirable, the cluster of bulbs and the old skins of decayed bulbs permitting the wet to drain away, and preventing the earth from lying too close and heavy on the bulbs in autumn and winter. Clusters have now stood unlisturbed at Spofforth above twenty years, with the precaution of covering them with leaves from November to April. There is danger in disturbing and parting them, for numbers will rot if reset separately; and if they must be divided it is best to do so in April, or, if it be done in the autumn, the roots taken up should be potted and turned out again in the spring." Many of the specific forms introduced since 1861 are hardy enough to stand out of doors unprotected. I had *G. Saundersii* flowering for several years in succession, but it did not increase, and died during the severe

frost in January and February, 1895. Even the garden varieties of the *G. gaudavensis* type will stand the winter in the open borders, and, in truth, some bulbs that had been left in the ground when the collection was taken up, have flowered very strongly the following season. I would point out to amateurs that the *Gladioli* is one of the easiest of plants to cross fertile or hybridise, and if the more recent introductions are still to be had, and suitable garden-soil available, no better or more interesting material could be had for an amateur to begin with. The seedlings flower strongly the second year. *Jas. Douglas, Great Gearties, Iford.*

THE CHRISTMAS ROSE.

Few hardy plants are more esteemed than the Christmas Rose (*Helleborus niger*), particularly the best forms of the plant now fairly plentiful in gardens (see fig. 5, p. 19). Briefly, it is the only plant in the open garden at this dreary season of the year that can be said to yield a good number of beautiful flowers, and this without much trouble.

At this season a few remarks of the culture of the plant will not be out of place, for though the plant has been an inhabitant of our gardens for something like four centuries (it was in 1596, according to London, that it was introduced from Austria), it is, in many instances, painfully evident either that the cultivation of the plant is not well understood, or the surroundings are unsuitable. I am not unmindful of the benefits of a good soil in the cultivation of the plant; at the same time, elevation, shade, and the like play important parts. But if we would follow nature in this, in some instances at least, we could only decide that these *Hellebore*s required an exceedingly shallow soil, and that granite chips formed the chief requirement of the plant. We know, however, from experience that the exact opposite is the fact, and that the plant invariably thrives in deep rich soils, especially in such that are rather clayey, if sufficient sand to prevent too much adhesion be added.

As to the granite chips, in the districts where I have seen these things do best no granite whatever existed, and in parts of Gloucestershire and Cheshire they are cultivated by the acre, and in similar quantities in the neighbourhood of Bath, where they are equally luxuriant. Nearer London the finest examples I have seen or heard of were only a few yards distant from the North Tower of the Crystal Palace; and in a private garden, of which for some years I had charge, were dozens of magnificent specimens about 2½ feet across. These also were in clay soil for the most part, and during December and January of each year these plants never failed to produce their handsome flowers by the bushel. Indeed, it was possible to gather dozens without their even being missed—rather it did good, as it gave room for the late buds to rise and expand. In this particular instance a very fine form of the major variety was grown, and the thick coriaceous foliage, which was most persistent, was an attraction in itself. This persistency on the part of the leaves of this plant is one of the surest signs of a perfectly happy condition, an item in the low lying fog-smitten county of Middlesex that is a great rarity. And where the foliage is well retained in this manner, the flowers push themselves forth with a vigour that is unknown in gardens where the greater number are cast during the summer heat. Giant clumps such as those named will send their roots down to a depth of 3 feet, and where this is the case all else will follow. One of the greatest mistakes in the culture of the Christmas Rose is that of attempting to move, or rather transplant, one of these big specimens intact, for the simple reason that the long roots refuse to give off fibres, the result being the rapid decline of the plant. Frequently the desire has been expressed to transplant a very large example in this way, but in each case I have recited a total failure of my own with one such plant, and though special soil to a depth of 3 feet was given, and the plant was only a few minutes being transferred to its new home, the whole thing was a hopeless failure. And some time later, when the plant

FIG. 5.—HILLBORNS NIGRA VAR. ANGUSTIFOLIUS. FLOWERS PURE WHITE. (SEE P. 18.)

had lost every leaf, and the great head of bloom refused to rise as usual, the plant was lifted and examined, only to find a mass of rotten and decaying roots where health and vigour were a few weeks before.

When these plants are well established they may remain for years in the same spot, content with a good mulching of manure as soon as the flowering is over; this will assist in keeping them cool during summer, and prevent the association of manure with their beautiful flowers. Then as to the time of planting, there are differences of opinion, as may be expected; but any who have made a study of the matter and time the new roots are produced by this plant will be alive to the importance attaching to planting in early autumn; while the need for this would appear greater for the southern than for the northern counties. Plants of about three or four crowns should be planted, and a deep bed of soil provided. Shade of a light kind is also of importance, and that provided by Conifers, Hollies and other shrubs is the right kind of shade. *E. Jenkins, Hampton Hill.*

COLONIAL NOTES.

CROP REPORT OF NOVA SCOTIA.

THE Provincial Government Crop Report of Nova Scotia is now to hand, and the secretary for agriculture, B. W. Clippinan, is "able to say that the promise there (last July) of a bountiful harvest has been fully realised, and the husbandman had abundantly rewarded for his labour. . . . It may be said generally that this is a most fruitful year, and the result of the harvest is of a very satisfactory character, if we except the Potato crop, caused by the excessive rains of the latter part of the season."

QUEENSLAND.

Mr. F. M. Bailey, the colonial botanist, has issued an addition to the series of his contributions to the *Queensland Flora*, containing descriptions of newly-discovered plants. Descriptions are also given of various plants from New Guinea. A deeply lobed frond of *Asplenium nidus* is figured.

NEW ZEALAND.

We have received the *Annual Report for 1895-96* of the government biologist of New Zealand, containing accounts of various fungi and insects in which the farmer is interested. It is satisfactory to find that the farmers are alive to the value of the labours of the biologist, Mr. T. M. Kirk.

COCKROACHES IN GRENADA.

We are free in Grenada from the parasite, which does so much harm in neighbouring islands, but I wish one could say the same of cockroaches, which abound here. Being so well known in all tropical lands, surely there must also be known some good remedies against their ravages to books. I should be glad of a few recipes to try. The one I use is painting the covers of books with diluted corrosive sublimate; it is a great check for a while, but has to be repeated rather often, and this is not such an easy matter where a library rapidly increases. Bookbinders would be conveying a great boon to those living anywhere in the tropics if they could mix some composition with their colours which would prove no tempting bait to this particular insect. Some shades of green, strangle to stay, are preferred by these pests, and a new copy bound in green of Schlich's *Manual of Forestry*, vol. iv. (1895), left on a table one night, has been spoilt in appearance by the white patches all over the covers, where the cockroaches have nibbled away the green. They are not adverse to gold, for the gilded titles at the backs of books are treated by them with scant respect. Some of Dr. J. C. Brown's works on Forestry, Water Supply, &c., are bound in a light green, which they do not touch; on the other hand, the Annual Reports of the Missouri Botanic Garden, and Bentham & Hooker's *Genera Plantarum* are not at all distasteful to them. What with cockroaches, mill-worm, &c., to keep in good order a library in the tropics is a great undertaking. *W. E. Broadway, Grenada, B. W. I. Dec. 8, 1896.*

THE ROSARY.

TEA ROSE, FIAMETTA NABONNAND.

I AM much obliged to "A. P." for the information given on p. 686 of the last volume of the *Gardener's Chronicle*; also for his kind observations regarding my previous contribution. Previously to reading his paragraph upon the subject, I was not aware that Fiametta Nabonnand was the result of a cross between Papa Gontier and Niphotos. I understood that the eminent raiser himself, M. Nabonnand, to whom we are indebted for many precious varieties, including l'Idéale, had described it as a "white Papa Gontier," which can hardly be regarded as an accurate description, if, as your correspondent asserts, it derives half its characteristics from Niphotos. I fear that some of our British rosarians have under-estimated the value of Fiametta Nabonnand, inasmuch as they have not included it in their catalogues. It is one of the finest Tea Roses I possess, and is quite as floriferous as either of its parents—and that is saying much. Climbing Perle des Jardins is a much more reliable variety for open-air cultivation than the incomparable Marschal Niel. The latter does not suit our Scottish climate, even when grown, as it is in my own garden, on a strongly-sheltered south wall. Its beautiful buds are almost annually ruined by the rains of early summer; it is only, indeed, in an exceptionally dry and sunny season that, inspired by such atmospheric conditions, they reach the full glory of the perfect flower. Nor, even when it reaches its floral perfection, does it exhibit the perpetuality of climbing Perle des Jardins. *David R. Williamson.*

REMOVING AND TRANSPLANTING FRUIT AND OTHER TREES.

(Continued from p. 79, vol. 21.)

It is probable that the removing and re-planting of larger trees will have greater interest for the gardener than the getting up and transplanting of ordinary nursery stock. To start with, roots are of two classes, according to their function, the large woody ones, including the tap-root, are to anchor the tree firmly in the soil; the finer ones, generally near the surface, are to nourish the tree. It is worthy of notice that trees, and especially Conifers, planted in sheltered belts among deciduous forest trees, or even nursed, as we call it, by Larch, having little need of the anchoring roots, develop chiefly the fine fibrous surface rootlets necessary to nourish the tree.

When, therefore, the Larch or other surrounding trees are thinned out or felled, the first strong wind topples them over, this being an especial danger where the surface soil is thin, resting on a chalk, stoney, or clay subsoil.

It follows, therefore, that in removing large trees to transplant them, the chief desideratum is to preserve, as far as possible, all the roots with their attached fibres, while most of the thick anchor-roots may be removed by the saw or axe, the tree being allowed to heel over when the soil has been all picked out from among the forking-roots, will generally permit this to be done. Should the tree be a very large and heavy one, it is best to have a tripod with blocks and pulleys, called a "gin," so that by means of chains or ropes, the tree may be lifted bodily out of its place, and while suspended, be cleared of its coarse roots, as well as have the bruised and broken ends of the rest removed by a sharp knife. This done, the tree may be placed on a broad-wheeled trolley, such as is used by stone-masons, steaded by gny-ropes, and hauled to its destination. Much now depends upon the skill exercised in preparing the hole to receive it, and a few hints for which I have to thank Mr. Holmes, of Brook House, Norwich, I will now give.

First, take care that the hole to receive your tree is made large enough, which may easily be assured by running a tape-measure across the roots, and getting out your hole at least 1 foot larger in diameter. The centre of the hole should be furnished with a good firm cone of clay, on

the apex of which the centre of the forking roots must rest, the anchoring roots straddling on either side, leaving the fine fibrous roots flowing all round. When the tree has been fixed in a satisfactory position, then the important operation of filling in the soil must at once be proceeded with. Let it be added a little at a time, evenly distributed among the root-fibres by the hand or a stick, and gently treading, so that there is not any part of the root, if possible, untouched by the added soil. Continue to fill in a little at a time, working it well among the roots and rootlets, and when all is replaced, let the tree be secured by gny-wires or ropes; but in using the first-named, take care to protect the hole of the tree so that the wire does not chafe or bruise it. I have seen at Brook House, Oaks 30 to 40 feet high, with a girth of 30 inches or more at 2 feet from the ground, successfully removed thus, and also a fine Foliage-tree of almost like proportions.

My practice has been, however, to prepare large trees for removal in the following manner:—In the spring draw a circle round the tree you wish to remove in the autumn, 2, 3, or more feet from the hole, according to the size of your tree, and take out a trench 2 feet wide round this line, as deep as you think necessary, to include all the roots, and then fill in with light-mould soil and brick-rubbish up to the ground-line. This will cause the severed and other roots to make plenty of fine fibre, in the way a plant confined in a pot does, binding the circular block of soil into a moderately compact ball. In the autumn remove all the added soil and rubbish from your trench, take off all the surface-soil down to the upper roots, and with a pick remove all you can get at from the bottom of the ball to lighten it. Now arrange your tripod over the centre of the tree, and affix your chain to its bole, first putting round it some coarse sacking to prevent chafing. Then raise the tree a little out of the hole, and with a fork pick out all the soil you can safely move to lighten it. This method is very convenient in the case of large Conifers, and I successfully moved eight Wellingtonias ranging from 12 to 21 feet in height, conveyed them by road a distance of nearly 20 miles, and replanted them without losing one, though the Wellingtonia is one of the worst Conifers to move when large.

The usual practice in nurseries is to lift and replant all stock at least once in three years, in order to make it safe to transplant whenever demanded; and this plan, because it prevents the formation of coarse woody roots while encouraging the production of many fine fibrous ones, is commendable for many reasons. First, it secures a good holding ball, which if the tree be properly planted, and at the right time, will insure the operation being successful. Trees and shrubs of all kinds so treated do not suffer from removal, therefore my advice to the planter is, pay a little more to secure such trees, as in the end it is more economical, as well as far more satisfactory.

This reminds me of an amusing episode in my experience. A gentleman doing extensive planting, used numbers of Scotch and Austrian Pines, and as long as the stock held out, was served with recently transplanted trees. But there came a time when the stock of such trees was quite exhausted, and the little remaining to do was done with Pines of the same age, that had not been removed for some time. This was very noticeable, as they had long sturdy shoots well furnished with foliage, and in a few days I had a letter from my client asking me to take up all the first planted, and supply their places with some more like those last sent. I used all my diplomacy to avoid this alteration, and await the result till next season. This was a dry, hot year, and though the unremoved Pines were watered and cared for, but two survived out of at least a score, while of the properly-prepared specimens, but one died. *Verbanus sup.*

There are a few subjects the nurseryman has to deal with that will not safely transplant from ordinary soils, notably among Conifers the large-fruited Cypress of Lambert (*Cupressus macrocarpa*), and its bright green coloured twin brother C. Lambertiana. These have a habit of growing out of all proportion to the size of their roots, so that should the soil be

NOTICES OF BOOKS.

HOW TO MAKE THE MOST OF THE LAND: A POPULAR GUIDE TO THE SCIENCE OF COMMERCIAL FRUIT CULTURE. By Sampson Morgan. (The Horticultural and Agricultural Bureau of Information, 4, Abchurch Lane, Charing Cross.)

The name of the author of this useful work is well known as that of an energetic and practical advocate of the extension of the cultivation of British fruit on a sounder basis than that worked by our forefathers. In the work before us, consisting of 105 pages of matter, including a capital introduction, the subject of how to make the most of the land is dealt with in a perfectly plain, clear, and practical manner, from beginning to end. The several paragraphs under the headings of The Science of Production, The Question of Varieties, Improved System of Culture, Land for the People, Factory and Field, Quality of British Fruits, Will Fruit Culture Pay?, Secret of the Market-Git, Potash for Fruit, Fruit and Wood, Commercial Fertilisers, Exhaustion of the Soil, Root Pruning, Thinning Fruits, Quality and Quantity, The Right Varieties, &c., afford much useful and trustworthy information, and sound advice, condensed into a small space, to market-gardeners and fruit-growers generally.

Under the headings of Profitable Glass-house Cultivation, Profitable Hardy Fruit Cultivation, Profitable Market Garden Production, Grapes, Tomatoes, Cucumbers, Strawberries, Asparagus (Hardy Fruit), Planting Trees, Apples, Pears, &c.; (Kitchen Garden), Cherries, Mushrooms, Potatoes, Cannibowers, and Asparagus, are one and all handled in a lucid and practical way under their respective headings; as also are the notes on the Science of Distribution, Markets and Market Salesmen, The Art of Packing, The Use of Punnets, Grading and Buyers.

Under the heading of Quality of British Fruits (p. 22), the author says:—"As I write I find that, after eight years' experience of the principles I advocated from the start, and in spite of increasing shipments from abroad, that during the present week, whilst the finest American Apples are being sold at from 10s. to 16s. per barrel of 3 bushels to the barrel, that English Cox's Orange Pippin, one of the special varieties I advocate should be grown freely, are selling in large parcels, and to arrive even—that is, in a market sense, being bought up by buyers before they are packed and marketed, at the rate of 9s. per bushel, and as against the American fruit equal to 27s. per barrel, topping the latter value by 10 per cent. when an average price is considered."

The author's practical and extensive experience of the kinds and varieties of fruits and vegetables which command a ready and profitable sale in Covent Garden is set forth in clear and forcible language, and is combined with sound cultural details, given in connection with the several kinds of fruits and vegetables which he recommends to cultivators.

How to Make the Most of the Land is a book which should be of great interest to all of those who are now embarking in the business of market gardening who may consult its pages, and who will do well to work upon the lines laid down by the author as nearly as circumstances will allow.

"The secret of the market-git," we are justly told (p. 23), "lies in a nutshell. It is used by heavy consignments of inferior products, or the marketing of produce for which only a limited or perhaps no demand exists. The market-git is caused by those who are ignorant of the market's needs. There never can be a glut of choice products; it is the careless producer of inferior grades of goods that is the cause of all the trouble. The planting of unsaleable varieties, and the marketing of ungraded goods, badly packed, will never answer in these days. The man who will not bring intelligence and skill to bear on the cultivation of the land ought not to continue in the business, and the sooner he gets out of it the better for all concerned."

In the case of heavily-cropped trees, the thinning of the fruit is recommended (p. 31): "This should

be done—first, to preserve the vitality of the tree; and, secondly, to ensure larger and better fruits of Apples, Pears, &c.;" bearing in mind "that five dozen giant Apples are worth two bushels of medium-sized fruits." Thinning will help in the production of marketable specimens. On the other hand, readers are reminded that the consequence of allowing the trees to overbear, "is to kill the goose that lays the golden egg."

With the above remarks, we have every confidence in recommending *How to Make the Most of the Land* to those who have hitherto, as now, exercised their minds a good deal on the all-important subject.

HARDY CONIFEROUS TREES. By A. D. Webster. (Hutchinson & Co.)

It is not everyone who possesses the *Report of the Conifer Conference*, held by the Royal Horticultural Society in 1891—a book containing a larger amount of information on the subject of cultivated Conifers than any other book in the language. So large is the mass of detail comprised within it, that many would be glad to get a digest of such portions as might be suited for their purpose. This they will get in a considerable degree in Mr. Webster's present publication, which, to quote the full title, is "A Concise Description of each species and variety, with the most recently-approved nomenclature, lists of synonyms, and best methods of cultivation; also chapters on the commercial aspect of Conifers, quality of British-grown coniferous timbers, Conifers for various soils and situations, Conifers of different characteristics, propagating Conifers, enemies of Conifers, &c." The chapters here enumerated have formed the subject of communications to the horticultural journals. The descriptions of the several trees taken from the living plants, though of little value to the botanist, are just what are wanted by the general planter, who does not care to be burdened with technical details. With respect to the discussion going on in these columns with reference to the Deodar, we may cite what Mr. Webster says:—

"This tree stands almost unrivalled in the grandeur of its little and beautifully-pendulous branches: indeed, it is open to question whether a more distinct and graceful hardy Conifer has yet found its way into this country. Few trees are more accommodating as to soil than the present species, but it is not well adapted for cold and exposed sites. . . . The rate of growth is rapid, 50 feet in height having been attained by specimens in England in fifty years. Timber produced in this country is fine grained, but soft, and not at all durable."

Under the head of the Lebanon Cedar, Mr. Webster notes a curious variety which sheds a considerable portion of its foliage every autumn, thus approximating to the Larch.

We should have welcomed some expansion of Mr. Webster's opinions as to the distinctions between the three American Spruces—*Picea alba*, *nigra*, and *rubra*. The latter form he refers to *P. nigra*, whilst *P. alba*, in our experience, is very scarce in cultivation. *P. nigra*, moreover, is one of those Conifers said to thrive in places where the roots are at times or constantly submerged. As these are points of some interest, we hope Mr. Webster may be able to furnish us with further results of his experience respecting them. Very valuable are the author's all-too-brief notes on the quality of British-grown coniferous trees, as affected by soil and situation (see p. 160, *et seq.*).

The variability of Conifers has naturally attracted Mr. Webster's notice. He calls attention to the fact that it is easy to recognise a particular species growing at a given spot, but often very difficult to determine the same species growing elsewhere. This will show how difficult and precarious must be the identification of Conifers from little twigs or wisps of foliage, such as are too frequently sent to the Editors of the gardening papers for identification!

Mr. Webster appropriately adds numerous references to his own communications in the various journals, and he would have done well to have been equally liberal in his references to the publications, and especially to the figures given by his predecessors. The Conifer Conference, at which were exhibited by far the most numerous collections of species ever

wet and light, the wind twists them round, blows them on one side, and I have known handsome specimens, 8 to 10 feet high, blown clean out of the ground. In nurseries, therefore, these difficult trees are grown in pots while young; but even this has its drawbacks, as unless they are looked after constantly they will make corkscrew roots. I therefore advise planting only quite young specimens of *Cupressus macrocarpa* or *Lambertiana*, which, by-the-by, are pre-eminently the best of all Conifers for the sea-side; and it will be found that these soon catch up and overtop any other Conifer, 3 feet in a season being no unusual growth for them to make.

Another difficult subject is *Quercus flex*, the Evergreen Oak, which should always be nursed in pots, and these plunged in ashes or other light material. The upright Evergreen Oak (*Q. Fordii*) and the vigorous and useful variety sent out by an Exeter firm, and called from this Lucombe's, with oblong entire leaves, as well as the Cork Oak (*Quercus suber*) are best nursed in pots, to ensure safe transplantation. Among flowering shrubs, the attractive and fragrant double Globe (*Ilex europæa fl.-pl.*), making long twisting roots with little fibre, is also usually grown and sold in pots. Do not attempt to get them out, but smash the pot with a blow of the spade, and plant with the portions of the pot still adhering to the ball. Some firms use perforated pots, but these are of little real advantage, as if the same are plunged for any length of time, the roots escape through the perforations, and the result is almost the same as though the plants had been nursed in the open quarters. The practice of growing young Conifers, Hollies, and other shrubs in Willow-baskets "en panier," common in Holland, Belgium, and France, is not advisable. The mycelium or spawn of various "Toadstools" (fungi) may be introduced into the ground to many ways, but most frequently by the agency of decaying wood. As everyone knows, the sapling Willow-was used in making baskets very soon decay, more especially when they are not "peeled." The continental panniers are made of these, and should the shrub or tree be planted just as received, the containing basket soon decays, and much flocculent mycelium is produced which will probably attack the living roots of the plant, especially those bruised or injured.

I think this of so much importance that I must ask to enlarge upon it, and having said all needful about transplanting, will finish with a few words about staking and protecting.

The common practice, when a tree is planted, is to drive a stake down close to it and parallel with the bole, and then to tie it securely to the stake, putting a wisp of straw or some soft material between to prevent chafing. In Kent and parts of Sussex, where the orchards are laid down as pastures, it is necessary to put a protecting cradle to the trees. This is made by driving down three or four split pieces of Chestnut, Ash, or Larch, and then nailing cross-pieces at intervals from the base to the top, forming the cradle. It is then a simple operation to tie the tree to each of the uprights at the top, and to make it quite steady, whatever wind may blow.

In plantations where it is not intended to allow grass to cover the soil, and sheep or cattle to graze between the trees, one or two stakes is enough, but these should never be put close to the bole, but at an angle, so that the points may not be near the roots, as this gives greater stability; and, moreover, should the stake decay at the base, the danger from the fungus spaw (mycelium) is not so great. I have known a fine orchard of young Cherry trees planted and protected by such cradles as I have mentioned, but when the trees had got to bearing size, they all at once began to show signs of ill-health; their leaves were pale and flaccid, and fell before their time, while in the next spring, the growth was short and stunted, and the colour pale and sickly. On being consulted, I at once divined the cause, and suggested exposing the roots of some of the worst affected. Surely enough we found a mass of mycelium smelling like putrid mushrooms, which had started from the decaying points of the timber, and had attacked the living roots of the Cherry trees. All the affected trees had to be cleared, and fresh soil substituted. *Experience.*

(To be continued.)

got together, and the report of which is most comprehensive, might almost never have been held for all the reference to it in this volume, though it must long be the quarry whence writers of books like the present must derive a large share of their information. Engelmann, Sargent, Gordon, Murray, Beisser, Fowler, Veitch, Hutchinson, Dunn were surely worthy of more conspicuous recognition than they get in these pages.

The writer claims for his book that it is intended as a "cheap, handy, and exhaustive popular guide to hardy Conifers." Exhaustive it could not be consistently with its other qualities, but the other adjectives are applied so appropriately that we cannot but heartily commend the book to the notice of Conifer-lovers as likely to be very useful to them, and as very free from inaccuracies.

ORCHID NOTES AND GLEANINGS.

CATTLEYA MAXIMA GIGANTEA.

This free-flowering plant bears handsome blooms, which appear at the present season. It is a comparatively old inhabitant of our gardens, and the plant, in the possession of the Royal Botanical Garden, Edinburgh, was purchased from an importation of Messrs. Little last year. The pseudo-bulbs vary from 1 to 1½ foot or more in height. In colour, the sepals and petals are of a light shade of rose with darker venations upon them; the beauty of the lip consists in numerous dark purple coloured lines, and a band of yellow running through the centre. When seen amongst flowering plants of *C. labiata autumnalis*, the contrast between its flowers and those of the latter is very noticeable.

R. L. H.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

To Grow Onions of Large Size.—Where bulbs of extra-large size are required for exhibition or home use, some forethought is necessary in selecting a suitable plot of ground in an open, sunny situation, and preferably one which has been deeply cultivated, and is in good heart. If this was trenched, or roughly dug, during the later months of the year, it will need no further attention till the middle or end of the month of February, at which time a good dressing of fresh soot, and a sprinkling of an artificial fertilizer, should be applied, and lightly forked in, which is all that need be done till the time arrives for planting in April. Seed should be sown now, or as early in the present month as possible, taking care to secure a good stock of a trustworthy variety or varieties, if such be needed. In sowing, shallow boxes filled to about half an inch from the top with light, rather rich, soil should be used, pressing the soil firmly. Sow the seeds thinly, and cover lightly, affording water a few hours afterwards with a fine rose can. It may be advisable to cover each of the boxes with a sheet of glass, mice being partial to the seed. Place them in a pit or greenhouse, with a temperature of 45° to 50°, and as soon as the plants appear, remove the glass, keeping the boxes well up to the light; and when the plants show the second leaf, prick them out into boxes filled with warmed soil, allowing to each plant a space of 2½ square inches, and keep close for a day or two till fresh growth commences. Give them a light position, and a temperature of 60° for a time, giving a little air on the hours or frame night, and increasing gradually as growth and the season advance, till they can be removed to a cold frame, and hardened by degrees. The aim of the cultivator should be to keep the plants sturdy and in a growing state till they are planted out, towards the middle of the month of April, or in northern counties a week or two later.

Early Peas.—If no Peas were sown outside in November, or having been sown have failed, a sowing should be made at this date in 3-inch pots, in readiness for planting out at the end of next month, or in March. A common error in raising Peas under glass is to afford them too much heat for the sake of getting them up quickly, thus causing the plants to grow weakly, and compelling them to early planting out. A better method is to place the pots in a cool pit or frame, from which frost can be excluded, for

although the seed will be longer in germinating, the plants will not make such a rapid advance, and the growth will be robust, and better suited for planting out-of-doors at the proper time than any that are raised in heat. Use pots that are clean, half fill them with moderately-rich turfy soil, and put six or eight Peas in each pot, filling up with soil. As the pots of plants should not be planted nearer together than 8 inches, it will be an easy matter to decide upon the number to be sown.

Dwarf Kidney Beans.—Continue to sow batches of these as required, place the seeds in small pots in a temperature of 65°, and when up keep near to the glass, thinning to three or four in each pot. When well into the third leaf shift into 8-inch pots, turning three small pots into one; use rich lumpy soil, and pot firmly, give them a light position, and grow on in a temperature of 65° to 70°.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

The Best Kind of Soil for Fruit-trees.—Fruit-trees generally delight in a strong, red, loamy soil, such as yields good crops of Wheat. It should be from 15 to 24 inches deep, and of average fertility. Where the natural soil is not of this description, the excavated holes should be re-filled with the most suitable mould that can be obtained; or if this cannot be done, a mixture may be made of some of the staple soil and some of the prepared loam, and a portion of this be placed around the roots of each tree. Road-scrappings and roadside-priggs may be added to light soils with advantage.

Varieties of Apples.—The following varieties should be included in a select list of dessert Apples:—Beauty of Bath, Irish Peach, Devonshire Quarrenden, Lily Suleley, Cox's Orange Pippin, King of the Pippin, Cox's Pomona, Worcester Pearmain, Ribston Pippin, Old Nonpareil, and Beauty of Kent. For culinary purposes, the following are good ones:—Kewick Codlin, Lord Suffling, Potts' Seedling, Lord Grosvenor, Northern Dumpling, Ecklinville, Stirling Castle, Emperor Alexander, Cellini, The Queen, Peasgood's Nonsuch, Blenheim Orange, Warner's King, Bismarck, Lane's Prince Albert, Northern Greening, Annie Elizabeth, and Hambleton Deux-Aus.

Varieties of Pears.—Of Pears, Doyenné d'Été, Clapp's Favourite, Beurré d'Amaluis, Conference, Marie Louise, and Pitmasot Duchess may be mentioned, being good orchard varieties.

Varieties of Plums.—Rivers' Early Prolific (sure bearer), River's Monarch, Victoria, and Belgian Purple will be found profitable varieties to grow in orchards or open garden.

Pruning of Fruit trees.—The pruning-saw and pruning-knife should be used discriminately, and those engaged in the work should have an intelligible object in view—in the case of young maiden trees for instance, the formation of large fruit-bearing trees in as short a time as possible. The young leading shoots of standards, pyramids, and bush-trees, should be pruned back to within from 5 to 8 inches of their bases during the winter months, but the sooner the operation is performed after the fall of the leaf the better. Each of the shoots so pruned will make four or five young growths the following spring. These, when likely to become crowded, or to cross each other in growth, should be pinched to within 2 inches of their point of origin. The strong leading shoots should be annually pinched two or three times during the summer and early autumn months, and the weaker ones once until the trees have attained to the desired dimensions.

Wall Trees.—Any trees that are affected with scale and thrip should be treated as follows: Withdraw the nails, burn the shreds, and paint the affected branches and shoots with a mixture of about 4 oz. of soft soap in a gallon of water, a wineglassful of petroleum, and sufficient clay and soot to give it the consistency of thick paint. Stir this well before it is applied to the trees, which should be after the trees have been pruned. The pruning of Pears, Plums, Apricots, and Cherries upon walls, should be proceeded with, and the necessary training afterwards. These trees—excepting Morello Cherries—should have the shoots spurred or cut-back to the wood-bud nearest their bases, and the old spurs where standing too close together on the individual branches should be thinned out to prevent crowding, an evil that should be avoided in all cases. A space of from 6 to 9 inches should be allowed between the shoots or branches of Apricots and Plums, but Pears require from 10 to 12 inches.

Every favourable opportunity should be taken advantage of to complete the nailing of the shoots of Morello Cherries to the wall. By reason of the great number of shoots which have to be manipulated, Morello Cherries require more time and skill to train them properly than other fruit trees which only require the shoots to be thinned-out a little as occasion requires, and the fore-shoots, if there be any, cut back to the basal wood. Strong leading shoots should be cut out where it may be necessary, in order to insure a proper balance of growth. If not already done, the nails and twigs securing the young shoots of Peach and Nectarine-trees to the wall should be drawn, the object being to prevent them flowering early by allowing a constant current of air to pass between the shoots and the sun-warmed wall, and with the same object in view, the process of re-arranging and re-nailing (as well as the pruning of the trees should be deferred until a week or two before the flowers begin to open.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Ho, Luton.

The Store.—Much will require to be done in the stove at the present time. Soils necessary for the potting of the various plants, should be placed in a convenient corner under cover. I do not favour elaborate composts, and as one kind of soil will not suit the requirements of all the plants, it is better to keep each separate, and mix them as required. All leggy Dracenas may be "tongued," and they will readily root if a little damp moss be placed round the cut, and moistened frequently with the syringe. Keep the plants moderately dry at the root, and the "toes" will then ripen, and may be potted up, or placed in a pan after the tongued heads have been removed. Crotons may be treated similarly, and pretty decorative plants may be obtained sooner by the tonguing process than by striking cuttings. Specimen plants should be shaken out and repotted. A mixture of three parts loam and one of peat, with a liberal addition of sharp sand and a dash of soot, suits them well, but it should be mixed together perfectly. If the repotted plants be placed over a little bottom-heat, it will be an advantage. *Aluminum Andromeda* is very apt to get leggy, and the plants should be cut down at the year, and exercised to preserve a few of the large fleshy roots upon the stem. Plant them in pots or pans in a mixture of rough fibrous peat, charcoal, and sand, surfacing the whole with a little living sphagnum-moss. The plants quickly lose health if the compost becomes sour, and every care should be taken to crock the pots efficiently. *A. Scherzeriana* is especially valuable; and being very free-flowering, it affords much material for cutting from. Give good drainage, the plants give very little trouble. They should be potted in September or October, but if the work was not done then, or earlier in the year, it may be done forthwith. When turning them out of their pots, it is well to have a tub of warm water near, and by placing the plants into this, all the old material will come away quite readily. The atmosphere of the stove should now be kept a little more moist, and a temperature maintained of 65° by night, and 70° by day.

Ferns.—If a house is devoted to these plants, their management is simple, but too much heat and moisture should not be given at the present time. *Adiantum cucumatum* at this season requires only sufficient water at the roots to prevent the fronds from shrivelling. *Gymogonias* should be kept at the warm end of the house. As the stems of Tree Ferns ought not to become dry, it will render frequent waterings unnecessary at this time of the year if common moss be tied around the stems. A temperature of 60° by night and 55° by day will be sufficient.

The Forcing-house.—This house will be greatly in demand at the present season, batches of double bulbs in variety should be placed in at intervals of ten days. Before putting in any potful of bulbs, be sure that the roots are in sufficient number to permeate the soil, and cover the sides of the balls. These bulbs may consist of *Hyacinths*, *Ixias*, *Narcissus*, *Tulips* of the early single-flowering varieties, &c. Home-grown Lily of the Valley clumps free readily at this date, and these associate well with *Spireas*, *Lilacs*, *Deutzias*, *Staphylea colchica*, *Roses*, and other well-known garden plants, helping to form a very pretty display under glass or in apartments. A few moderate-sized specimens of *Persias* and large-flowered *Lilacs* may with advantage be lifted from the shrubberies, potting or tubbing them; or if only the flowers are to be used, they may be bedded in a

forcing-house. The potted plants may be stood in any house in which forcing has begun. *Rhododendrons*, *Gaultheria*, *Rose*, &c., may be similarly treated. *Dielytra spectabilis* is a useful plant when strong masses of it are taken up for forcing, furnishing flowers which last well when cut, as do those of *Solomon's Seal*. The last-named gives first flowers, and afterwards foliage that is useful in various ways.

General Work.—*Cycladium*: a few of the early rested tubers may now be potted up and placed in the forcing-house. For early work, *C. argyrites* is invaluable, it being useful for cutting from, and as small table or vase plant. Put them in 3-inch or 4-inch pots, and do not allow them to touch water until root-action has commenced, or the bulbs may decay. A few *Gloxinias* may also be potted up. They are very effective when in flower if brought among plants of *Adiantum crenatum*, and the cornus should be potted up at intervals in batches. Carnations intended to flower in April, May, and June may be kept cool; and provided the plants were potted up in the autumn, the pots will be well filled with roots. Too much water is very injurious to them. If a house or heated frame is given up to their culture, fire-heat should be used only to prevent damping and keep out frost. We necessarily use the fire-heat, and fan-ventilate the structures occasionally. They conceal themselves among the young unfolded leaves at this time of the year, and the injury resultant is apparent before the cause. Should fungoid disease appear, apply the following mixture to the plants by means of a spray-syringe. It will check the disease, if not absolutely kill it, and may be applied once each week. Take 2 lb. of sulphate of copper and dissolve it in 2 gallons of warm rain-water; also 3 lb. of crystal soda, and dissolve in 1 gallon of hot water. When all is dissolved mix the two solutions together, and add 1 1/2 oz. of liquid ammonia, and 1 oz. of potash. Use 11 pints of mixture to 25 gallons of water. That not required for immediate use should be kept in an earthenware or glass bottle tightly corked.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Phaiolipsis (Doubrochilium).—Owing to the species of this genus being natives of Java and the Philippine Islands, it has been supposed that they require the highest temperature available in our Orchid-houses. Such, however, is proved by practical experience to be wrong. Such species as *P. glauca*, *P. Cobbiana*, *P. filiformis*, and *P. unguis*, when grown always in strong heat, are more or less attacked with red-spider, and consequently fail to maintain their green, healthy appearance. *Phaiolipsis unguis* has been in flower here for several weeks past, and it still appears to be quite as fresh as when the first raceme opened. It is an easily cultivated species, and well-bloomed plants form very pretty objects during this dull season. The flower-spikes are produced from the centre of the young breaks, which at this date are but half grown. Afford the plant therefore copious supplies of water until the bulbs are fully matured. The plant should be suspended close to the roof-glass in the intermediate-house in a rather moist and shady position. The summer flowering *P. filiformis* is now at rest, and should also be suspended in the intermediate-house at this period. Keep the compost just moist by occasionally syringing the foliage on warm sunny days; this will help to preserve the bulbs and leaves in a fresh and plump condition. *P. Cobbiana*, having recently completed its growth, should be similarly treated. The spring-flowering *P. glauca*, has been since last July in the coolest part of the intermediate-house, but now that it has commenced to grow, a few degrees more warmth has become necessary. The roots, when about 2 inches high, commence to send forth a number of roots which quickly enter the soil, and if the plant requires re-potting, this is the time when it should be done; but if it is inconvenient to repot the plants at this time, re-potting should be done immediately after the flowers fade. *P. glauca* *valida*, requires identical treatment. It can be distinguished from the type by its pale green-coloured growths, more robust habit, and its shorter but less graceful inflorescence. All the species root freely in a compost of peat and sphagnum-moss chopped rather finely. The pots or pans should be shaded with clean white paper between crocks. After such re-potting, the surface of the compost should merely be kept moist until the flower-spikes are seen, when the supply should be gradually increased.

Callipogon-house.—*Calyceum Dayana* is at rest in this house, and requires sufficient water only to keep the

bulbs from shrivelling. The pretty dwarf *C. Rossiana* now flowering from its young growths, may be repotted after the flowers fade. *C. flaccida* and *C. lactea*, both being at rest, should be kept rather dry at the root until growth recommences.

In the *Cook-house*, plants of *Maxillaria Sanderiana* are developing their flower-spikes, which go in a downward direction; and any plants in pots should be examined, and pieces of stick or glass be placed under the spikes, or these will push through the compost into the drainage.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Easton Castle, Ledbury.

Strawberries.—Plants for early forcing that were brought into heat in November will now be fast opening their flowers, requiring to be kept dry overhead and not too moist at the roots, allowing them air on all suitable occasions. To favour the setting of the blooms, the trusses should be gently agitated so as to distribute the pollen. As soon as most of the blossoms are set, thin these to from four to six fruits on a truss, leaving fruits on the main stalks which have the most promising appearance. Increase the temperature to from 55° to 60° at night, according to the state of the weather, with a corresponding increase by day; syringe the plants twice a day, and fumigate lightly if any aphids be observed. Afford the plants weak manure-water in gradually increasing strength, until colour is seen in the fruits, when it must be discontinued, and more air afforded, so as to heighten the flavour. Introduce plants for succession at intervals of a fortnight or three weeks, and before doing so remove the dead leaves upon them, and remove the crust of soil lightly, replacing it with fresh loam and a pinch of artificial manure, and see that no worms are left in the balls; wash the pots, and dip the foliage overhead in a weak solution of soft-soap and tobacco-water, or any other safe insecticide. This is a very necessary precaution when the plants have to be forced in vineries and peacheries. The plants for various successions should be protected from the inclemencies of the weather, but well exposed in mild weather, or when only slight frosts prevail.

Melons.—Seed may now be sown if ripe fruits are required for table at the end of the month of April, sowing in small 60's about three parts filled with friable loam in not too dry a state, two seeds in each, covering lightly, and placing a little damp moss over the soil, in order to prevent evaporation of its moisture, and render watering unnecessary before the plants are up. Plunge the seed-pots in a bottom-heat of about 80°, and select the strongest plant in each pot when a true leaf is made; top-dress with loam at the same temperature as the hot-bed, and keep the plants up to the glass, so that mowing may be prevented, and fill plants in the pots more or less, as the roots will be chilled, and a severe check given. Afford water very sparingly, but avoid wholesome dryness at the root. The Melon house should now be got ready by giving it a good cleaning in every part, limewashing walls, &c. I prefer 12 or 14-inch pots for early Melon growing, plunging these to the rims in a mild but steady hot-bed made up of leaves and litter. On the layer of crocks place a sod, the grass side of which should be turned downwards; press the soil firmly, and above it place a quantity (three-quarters of the whole) of rich, heavy loam that has been stacked for a year, one part line-rubble, with a small quantity of fresh soil well mixed together. Place the pot in the hot-bed so as to thoroughly warm the soil throughout, and beat the soil firmly before planting. The young plants should be placed in the pots before they get pot-bound. Keep the plants well up in centre of the pots, sloping the surfaces gradually to the side, so as to prevent the water saturating the soil close to the stem. It is well to have a ring of zinc about 3 inches deep and 6 inches in diameter to clip round the plant, as it serves as a guard against slugs, &c., and by never allowing water inside the ring, it forms a preventive of canker. Keep up a normal temperature of 65° to 70° at night, rising to 75° or 80° with fire-heat by day, and to 85° by sun-heat, affording air very sparingly, and avoiding cold draughts by all means. Air should be taken off early in the afternoon, the plant being capable of standing much sun-heat without injury. Rub out all side-shoots from the stem till the trellis is reached. Cover the glass at night if frosty weather prevails, as it is both beneficial to the plants and economical fuel. Where a constant supply of plants is required, a few seeds may be sown out at a fortnight. Where pot-used, room can often be found for a plant in Pine-pots, and the fruits thus obtained often prove useful additions to the dessert.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Drogheda, Maidenhead.

Planting.—The planting and transplanting of trees and shrubs not having been delayed by severe frost up to the time of writing, is in most localities in a forward state, but if these operations have been delayed from other causes they should be pushed forward whenever the ground is not frozen or too moist. Although, as we all know, deciduous plants are the better for being planted in the early autumn months, they may yet be planted provided the work is properly done. A light soil resting on a porous subsoil soon gets rid of its moisture, and on such soils planting need not be long delayed after rain has ceased to fall. It is, however, different with tenacious soils, and these must not be touched till they have been dried by the action of the wind and sun. Evergreens may be left till the spring on any soil, unless the root-masses are large, and they can, from the nature of the soil, be kept intact. As a rule of general practice, plant these in early autumn, or in the month of April. In planting new subjects in old shrubbery borders or other parts of the garden previously occupied by trees and shrubs, the stations for the new plants should be wholly or partly renewed with fresh soil, and manure in a rotted state. If balls are not planted, the roots must be spread out at right angles to the stem, after removing the damaged portions. Cover these with a few spadefuls of the new mould, shake the tree, then add more mould, and some of the staple, if it be not too poor, and make the plant firm in the soil by lightly tramping it, fill up the hole, and allow for the subsidence of the soil by mounding it somewhat against the stem. Standard trees and large-headed bushes need to be staked and tied, the latter being done loosely, and the ground around afforded a mulching of rotten dung or partially-decayed leaf-mould.

Deciduous Flowering Shrubs for the decoration of a shrubbery may include the following, some being suitable for forming specimens, and all are fit for planting in shrubberies, on banks, &c. Of shrubby Syringas there are *arborescens*, flowering in June, and for use as a handsome specimen plant for the lawn; and although its flowers are not of a pure white, they are gracefully borne in drooping panicles. *S. Douglasii*, flowering in July and August, is rose coloured; *S. Lindleyana* is a very distinct variety with large erect panicles of white flowers and handsome pinnate foliage; *S. confusa*, white, ornamental flowers, grows from 3 feet to 4 feet high, and is suitable for the front of shrubbery borders; and also *S. callosa* *alba*, 2 feet high, is not out of place in the herbaceous border. Syringas, commonly known as Lilacs, have received several noteworthy additions of late years, both in double and single flowered forms, and these are chiefly of continental origin. These are well worth adding to collections where only the older varieties exist. Among the single flowered, *S. Souvenir de Louis Speth*, dark reddish-purple, is a very distinct variety; and *Marie Legraye*, pure white. Madame Lemoine and *Virginie* are good double-flowered whites; *Léon Simon* has double flowers of a lilac colour; *Le Gaulois* is also double, and red-coloured. The *Philadelphus* should not be omitted. *P. coronarius* (mock orange), long an inmate of our parks, is one of the most noteworthy, while *P. grandiflorus*, although less marked in this respect, is a pure white, with larger flowers, and is altogether a desirable variety for shrubbery planting; and there are several other of lesser growth well deserving of attention. Standard Thorns may be used with effect, especially those with double flowers, in scarlet and pink, and other shades, should be found a place, and the single-flowered varieties being also deserving shrubs. Among the earliest shrubs to bloom is the *Almond*, of which there are single and double-flowered varieties in colour varying from pale pinkish-white to rose and crimson, and the double colour form found in the double forms of *Amygdalus persica*, *d. pl.*, or double-flowering Peach.

CHRISTIES.—There is such a thing as analysis and such a thing as synthesis, and the study of each is of equal interest from the point of view of the student. It is not pleasant to think of the break up of old collections, whether of pictures or of plants, on the other hand it is satisfactory to see good things dispersed among the appreciative; and thus, we leave no doubt, Mr. ROBERTS' forthcoming *Memorials of Christie's*, to be published by Messrs. BELL & SONS at once, will be a work over which the connoisseur will glaze with eager interest.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

TUESDAY, JAN. 12 } Royal Horticultural Society, Stan-
dard Committee.

WEDNESDAY, JAN. 13 } Refreshment Gardeners' Society

THURSDAY, JAN. 14 } Gardeners' Royal Benevolent In-
stitution. Election of Pensioners
at "Simpson's," Strand

SALES.

MONDAY, JAN. 11 } English and Foreign Border Plants,
Lilies, &c., at Stevens' Rooms,
Tuberose, Gladioli, Spireas,
Roses, &c., at Protheroe & Morris' Rooms.

TUESDAY, JAN. 13 } Azaleas, Calceolias, Carnations,
Iris, &c., at Protheroe & Morris' Rooms.

WEDNESDAY, JAN. 13 } 1000 English-grown Roses, Fruit
Trees, Border Plants, Palms, &c.,
at Stevens' Rooms.

THURSDAY, JAN. 14 } 34,000 Japanese Lilies, Roses, Palm
Seeds, Begonias, &c., at Protheroe
& Morris' Rooms.

THURSDAY, JAN. 14 } Roses, Clematis, Gloxinias, Dahlias,
&c., at Protheroe & Morris' Rooms.

THURSDAY, JAN. 14 } Trade Sale of Japanese Lillians, at
Stevens' Rooms.

FRIDAY, JAN. 15 } Azaleas, Dutch Bulbs, Roses, &c.,
Established and Imported Or-
chids, at Protheroe & Morris' Rooms.
Miscellaneous and Miscellaneous
Property, at Stevens' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of forty-three years, at Chiswick.—36°.

AIRIAL TEMPERATURES: LONDON.—January 6: Max., 18°; Min., 26°. PROVINCES.—January 6: Highest Temp., 34°; S.W.; Lowest, 40°, Scotland.

The Persian Cyclamen. In a recently-issued number of the *Journal de la Société Nationale d'Horticulture de France* we find

a very interesting and useful paper on the cultivation and mode of growth of the Cyclamen, by MM. ALEX. HÉBERT and GEORGES TRUFFAUT, from which we extract what follows as likely to be of interest to our readers.

The first Cyclamen from Palestine was imported into France, at Lille, in 1731, and which attracted such attention, that a single plant was purchased by the well-known amateur florist, the Monk REYNTKENS, of the Abbey of St. Peter at Ghent (Belgium), for the large sum—for that period—of 65 francs. From this plant have been derived for the most part the innumerable varieties of Cyclamen which now everywhere abound.

At the end of the sixteenth century these plants were in great demand, but they eventually went out of fashion until the early years of the present century. In 1844, M. DE JONGHE of Brussels published the first monograph of the genus, with details of its culture. In France, about the year 1849, a distinguished horticulturist, M. FOURNIER, exhibited plants

of Cyclamen of many distinct forms, and brought it more extensively before the public. The late CHARLES TRUFFAUT, in his establishment at Versailles, developed and improved the varieties immensely, raising more than 2000 plants annually; but they again went out of demand until the years 1876-78, when a special effort was made in France to bring them to the fore once again, since which time they have held a worthy place in most horticultural establishments.

In its natural habitat the Cyclamen of Persia is met with in temperate regions, in mountainous and dry situations. They grow by preference in sandy-loams that contain a certain amount of humus, but they cannot thrive if stagnant water exists in their vicinity. Normally, their blossoming takes place in the spring, and usually it occupies three years to mature the plants, but by improved methods of culture, the Cyclamen is made to produce its flowers in one year, which is of great advantage from a commercial point of view. But the authors say this rapid method of obtaining fine plants is no easy matter, as they are very capricious in their habits.

In order to learn something of the food requirements of the Cyclamen, and the best methods of developing the genus, the authors submitted sixteen plants of *C. persicum* (pure white) to chemical analysis. They had been grown in a cold-frame in a mixture of leaf-mould and sandy-loam, and had been watered during the period of active growth with a weak solution of cow-dung manure.

The following are the results:—

WEIGHT OF PLANTS, DRIED IN GRASS.	WIGHT OF PLANTS, DRIED IN GRASS.	
	In fresh state	In dry state.
Flowers	7.06	0.75
Leaves	22.68	2.25
Stalks	30.62	3.00
Tubers	23.96	2.32
Whole plants	94.42	8.62

Chemical Composition.—Per Cent.

Organs.	Dry Substance		Nitrogen.		Ash	
	In fresh.	In dry.	In fresh.	In dry.	In fresh.	In dry.
Flowers	10.6	0.209	1.78	0.296	9.10	
Leaves	9.9	0.240	3.41	0.651	6.58	
Stalks	7.5	0.141	1.89	1.261	16.22	
Tubers	11.4	0.155	1.56	1.730	15.31	

Composition of the Marsh Ash of the Cyclamen.

	Per Cent
Silica	17.30
Chlorine	7.96
Sulphuric acid	7.45
Phosphoric acid	0.22
Oxide of iron and alumina	10.00
Lime	4.36
Magnesia	6.42
Potash	2.40
Soda	12.82

These figures show that the Cyclamen in regard to their chemical composition approach very near to the terrestrial Orchids. They contain a considerable proportion of water, more than 90 per cent., and relatively to other plants but little ash or mineral matter, and not much of the element nitrogen. The analysis of the ash shows that it is particularly poor in phosphoric acid, but rich in potash, and somewhat less rich in soda. They appear to be the poorest in phosphoric acid of any plants yet examined except Ferns, and very low in lime and magnesia.

From the data thus given it appears that the Cyclamen is not very exhausting in its effects upon the soil for either nitrogen or mineral ingredients. At the same time the authors feel assured that a careful selection of soils will do much to meet the food requirements of these

plants. They have further tried the effects of various artificial manures upon the Cyclamen, but hitherto with not very satisfactory results. They experimented with plants of a "good" and of a "bad" strain. The relative weights of the various organs of the two different series of Cyclamen were as follows:—

Weight in Parts per Hundred.

Organs.	Good Strain.	Bad Strain.
Flowers	7.64	1.96
Leaves	24.74	31.32
Stalks	42.87	39.22
Tubers and Root Fibres	24.95	24.50

It is thus seen that the principal difference between the good and the bad strain is in their proportion of blooms, the good having the best flowers, while the bad yields the largest percentage of leaves.

The chemical analysis of the inferior Cyclamen showed that they did not differ very materially from the well-grown plants. They contained a little more nitrogen, more chlorine, magnesium, and soda, but less of silica and potash.

The cause of failure in Cyclamen culture is therefore put down by the authors to unsuitable soils, and that there is a danger in the composts used being too rich, which would favour a too rapid formation of vegetable-tissues, and hence lead to leaf-growth instead of blooms.

The question of watering, the authors consider as very important, chalky waters being thought to be particularly harmful.

The general conclusion is that—1. Under the influence of forcing manures the Cyclamen increases in total weight of plant, but the foliage is encouraged at the expense of bloom-formation.

2. Successful culture can only be attained by a suitable selection of soil, which should be leaf-mould with a mixture of sandy-loam.

3. Should the plants look sickly, they will be benefited by being watered near the roots with a liquid-manure containing a quarter of an ounce each of nitrate of soda and iron sulphate to 2 gallons of water.

We have received from Mr. WOOD a reply to Mr. DOUGLAS' letter in our last issue, but in

view of the probability of further correspondence on the subject we think it better to postpone the publication of Mr. WOOD's letter till others have had the opportunity of expressing their opinions. We hope they will do so as tersely as possible. Gentlemen who send us numerous sheets of manuscript can hardly be aware of the fact that each week we receive far more "copy" than could be possibly inserted were the *Gardeners' Chronicle* doubled or even tripled in size. Mr. T. H. SMITH obliges us with long communication in which he expresses the opinion that some project of the kind ought to be started, and goes on to propose the establishment of a "Queen Victoria Horticultural College." His scheme involves the establishment of a "theoretical and practical training college, a horticultural institute, a home for visitors interested in and following the profession, and a medium for giving to the public displays of horticultural merit periodically throughout the year." Mr. COLLERHEAD puts forth another scheme at p. 32 with reference to a 300-guinea cup for *Chrysanthemums*! We reserve the expression of our own opinions on these and cognate schemes for a future time

CIRRHOPETALUM MEDUSÆ, LINDL. — Our illustration (fig. 6) gives a representation of this very fine Malayan species (the *Bulbophyllum* *Medusæ* of Reichenbach), which was prepared from a photograph of a specimen that flowered recently in the collection of Sir Trevor Lawrence, Bart., Burtord, Dorking (gr. Mr. W. H. WHITE). Although as a note published in the *Gardener's Chronicle*, April 2, 1842, p. 224, well indicates the plant has been in cultivation for many years, it has always been rare; and probably during the whole of the time that it has been known, no such plant as that now illustrated has been flowered. It will be

there are no absolute marks of distinction between *Cirrhopetalum* and *Bulbophyllum*, the two genera being kept up for convenience sake, and to avoid the confusion that would arise if they were amalgamated.

ROYAL HORTICULTURAL SOCIETY. — The first meeting of the Royal Horticultural Society in 1897 will be held in the Drill Hall, James Street, Westminster, on January 12, from 1 to 4 p.m. On or before that date, the Society's new book of arrangements, containing particulars of the shows, lectures, committees, &c., for 1897, and the report of the Council, and new list of Fellows, will be issued.

seconded by Mr. CHILLY, the Mayor (Mr. C. W. DYSON PERKINS) was elected Chairman of the Executive Committee. Subscriptions were announced from several new members. Other business of a routine nature having been disposed of, Mr. YOUNG, called attention to the fact that many gardeners in the district were members of the institution but not of the auxiliary, and suggested that some steps should be taken to bring them into it, but nothing was decided upon.

— The fifty eighth annual general meeting of the members of the Gardeners' Royal Benevolent Institution will be held at "Simpson's," 101, Strand, in the

FIG. 6.—*CIRRHOPETALUM MEDUSÆ*: FLOWERS PALE YELLOW.
From the collection of Sir Trevor Lawrence, Bart., President of the Royal Horticultural Society.

seen that the inflorescence consists of a number of flowers, in each of which the two lateral sepals are elongated, the whole forming a head, which caused Dr. LINDLEY in his description to remark—"Certainly it ever there was a *Medusa*, this must be the prototype, before her Gorgonship's beautiful tresses were changed into serpents, nor are wanting the scales with which her form was safely guarded. It is an evergreen species, with creamy-white or pale yellow flowers, and it requires to be grown in a warm, moist house; and, although after the pseudobulbs are fully made up, it is benefited and rendered more certain to flower by water being given rather sparingly for a time, it does not require drying off in the ordinary acclimation of the fern. In the *Flora of British India*, v. p. 757, Sir JOSEPH HOOKER places this plant under *Bulbophyllum*, though he ad-

GARDENERS' ROYAL BENEVOLENT INSTITUTION. The first annual meeting of the Worcester and District Auxiliary of the Gardeners' Royal Benevolent Institution, was held on Saturday, Dec. 19, at the Guildhall, Mr. R. C. SMITH CARINGTON in the chair. The balance-sheet for the year showed that the receipts were £175 3s. 6d., and the expenditure £172 5s. £161 15s. of which has been sent to head quarters in London, leaving a balance in hand of £34s. 6d. The committee, in their report, expressed their sincere thanks to those who had given such handsome donations to the branch and especially to EARL BEAUCHAMP for kindly allowing his gardens to be thrown open for the benefit of its funds on the proposition of Mr. CHILLY, seconded by Mr. HUBBARD, EARL BEAUCHAMP was elected President, and on the proposition of the Chairman,

County of Middlesex, on Thursday, January 11, 1897, at 3 p.m., for the purpose of receiving the report of the committee and the accounts of the Institution for the present year, electing officers for the ensuing year and other affairs, and also for the purpose of placing twenty pensioners on the Fund, ten of whom came in number Rule III s. 5, and ten by the votes of the subscribers. The usual annual friendly supper will be held at 6 p.m., after the business of the meeting has been disposed of, H. E. MULNER, Esq., F.R.S., in the chair. Friends of the Institution who may wish to be present at the supper should forthwith communicate with the secretary, Mr. GEORGE J. INGRAM, 50, Parliament Street, S.W.

MEMORIAL OF THE QUEEN'S REIGN. — The subject for discussion at the next meeting of the Horti-

club on Tuesday, Jan. 12, at 6 P.M., at the Horticultural Club Room, Hotel Windsor, Victoria Street, will be "Proposals for a Horticultural Memorial of the QUEEN'S REIGN."

MR. HARMAN PAYNE.—The Council of the National Horticultural Society of France at its next meeting held in Paris, elected Mr. HARMAN PAYNE a corresponding member of the Society, in recognition of his services to horticulture.

JOTTINGS FROM KEW.—"Gardeners'" plants have made a fine display in the Royal Botanical Gardens, Kew, during the past few weeks, and we may instance the *Chrysanthemums*, *Michaelmas Daisies* in pots, the fragrant and floriferous *Marguerite-Carnations*, the vividly coloured *Salvia splendens*, besides others, as S. Detelli and S. leucantha, all of which are worthy of high culture where roomy greenhouses and conservatories have to be made gay at this season. The beautiful Himalayan *Laetia grisebachii* is showing fine heads of its white and pink sweet-scented flowers, which will continue to open in abundance for several weeks longer. *Tecoma Smithii* has been flowering in small examples in 5-inch pots. These plants, growing about 2 feet in height, and being furnished with good heads of orange-coloured blossoms, are most desirable additions to greenhouse decorative plants at the winter season. The plant flowers in from 6 to 8 months from seed. Brief mention may be made of the many beautiful *Bouvardias* in flower, of *Eupatoriums*, *Benjamins*, and *Rhododendrons*.

THE DEVON AND EXETER GARDENERS' ASSOCIATION held its annual supper on New Year's Day. Owing to the inconvenient date, which was unavoidable, the number of members present was not equal to that on most former occasions. Considerable enthusiasm distinguished the proceedings.

THE TRENTHAM AND HANFORD Horticultural Society's Show for 1897 has been arranged to take place on Thursday, July 22.

GREAT BRITAIN'S CEREAL CROPS.—The Board of Agriculture has just issued a leaflet entitled, "A Preliminary Statement showing the Estimated Total Produce and Yield per Acre of Wheat, Barley, and Oats in Great Britain in the Year 1896, with Comparative Statements for the Year 1895, and for the Average of the Ten Years 1886-1895." It appears from the figures that the estimated total produce of Wheat in Great Britain in the present year was 57,052,952 bushels; the total for 1895 was 57,176,257 bushels. The average for this year is 1,693,957, against 1,417,183 in 1895. The estimated yield per acre was for the present year 33'68 bushels, against 26'23 for 1895. The average of the ten years, 1886-1895, is 28'81 bushels. Coming to Barley, and under the same conditions, we find the estimated total produce for 1896 put at 70,774,776 bushels, against 68,650,945 bushels last year. The average for the present year is 2,104,761, against 2,166,279 in 1895. The estimated yield per acre for the current year is 33'63, against 31'69 for 1895. Average of the ten years, 32'68 bushels. Oats were estimated at 111,915,967 bushels for 1896, and produced 122,148,628 bushels last year. Average, 1896-3,495,488, against 3,296,063 last year. The estimated yield per acre for the present year is 36'83 bushels, for last year 37'06 bushels. The average of the ten years, 1886-1895, is placed at 35'23 bushels. These figures, we think, will be found of much general interest.

GENERAL EXHIBITION AT HAMBURG, 1897.—We learn from the third supplemental programme, issued by the authorities, that a special scientific section has been decided upon, which in regard to its more important divisions will be opened on May 25, together with the first special exhibition, and kept open till the close of the general exhibition, towards the end of September. The chief features are (1), the diseases of cultivated plants occasioned by atmospheric conditions, by the nature of the soil,

and those of a mechanical nature. This section will include wounds and their treatment, grafting, budding, etiolation, bark canker, frost canker, frost wounds and cracks, injury by storms, hail, lightning, smudge, chlorosis, dwarfing, &c.; (2), the animal and vegetable foes of horticulture and fruit culture, with reference to the difficult question of the boundary line between agriculture and forestry; (3), the diseases, malf ormation, and destruction caused by these foes of cultivated plants, and the remedies and preventive means employed against them. The creatures and plants useful to vegetation: (4), the more important insects instrumental in the fertilisation of flowers, together with examples of their activity in suitable preparations, models, pictures, &c.; (5), useful root fungus (tuberules of bacteria, mycorrhiza); (6), the chief foes of the insects injurious to plants, and fungi which destroy insects; (7), monstrosities and deformities of plants, union, gours, leafing, doubling, examples of low roots pierce hard substances; (8), comparative trials of the effect of manures on plants grown in pots, commencing on July 30, cultivation in feeding solutions; (9), wild forms of cultivated plants (dried or living); (10), exotic plants in pots of use in commerce, manufactures, &c.; (11), selections of the more important useful exotics in a preserved state (dried, in alcohol, &c.), as well as different parts and organs (flowers, fruits, seeds); (12), selections of plants and parts of plants (flowers, fruit, seeds, germinating plants, &c.) arranged according to morphological and biological standpoints; (13), results of scientific experiments in pollination, and when possible with the original species; (14), scientific adjuncts to instruction in horticulture: (a), the literature of gardening, that concerning the management of parks, fruit culture, injurious insects, and pollination of flowers by insect agency (the same being provided and set up by the committee); (b), pictures, models, microscopic preparations, photographs on glass, &c.; (c), pictorial or graphic exhibitions of the feeding properties of fruits and vegetables.

MR. JAS. CYPHER of Cheltenham, celebrated the attainment of his seventieth birthday on the 1st inst., when the employees of the nursery business of which Mr. CYPHER was the founder, met the members of the firm at a complimentary dinner. The company present numbered seventy-eight, and an enjoyable evening was spent.

BUDDING THE LEMON.—Theory and fact, which are so often opposed in fruit-growing, were diametrically opposite in the matter of propagating Lemon trees. Theorists, says a correspondent of *Garden and Forest*, argued that the best Lemons must necessarily come from trees grown from Lemon seeds, or from cuttings taken from Lemon trees. They saw an absurdity in budding the Lemon, which is a sour fruit, on to an Orange, the most desirable quality of which is sweetness. Yet this apparent contradiction is now universally practised in southern California, after years of discussion and experimentation. The Lemon does not come true to name from seeds, and buds which are grafted upon an Orange-root produce better fruit than buds grafted upon a Lemon-root. This was long a vexed question, and is a good illustration of the fact that experience alone can teach what is best in the growing of fruit.

PROPOSED BOTANICAL GARDEN FOR ABERDEEN UNIVERSITY.—At a meeting of the Aberdeen University Club recently, the Marquis of HENTLY, Lord Rector, presiding, a communication was submitted from Dr. JAMES W. H. TRAIL, Professor of Botany in the University, representing that there is no provision within the University for teaching vegetable physiology practically in such a way as to enable students to study growing plants, and to observe the effects on them of experiments, or of varying treatment or environment. A botanic garden had for a number of years been included in the list of the more pressing needs of the University, issued year by year in the "Calendar." It had been rendered urgent and indispensable by the ordinance for degrees in pure science and in agriculture. He was

not aware of any other university or science school of far lower rank than the University of Aberdeen in which there is absolutely no provision to enable students to study living plants as affected by varying treatment. He suggested that such a garden should be provided, restricted to the cultivation of plants in the open air. The most suitable ground for the purpose, within convenient access of the University, would be the field to the west of the garden of the manse of the Professor of Biblical Criticism. It belonged to the University, was of convenient size, was easily accessible from Bedford Road, was sheltered from east, north, and west, and had a varied surface that would adapt it to the cultivation of plants of different requirements from very dry to very wet habits. Mr. NICHOLSON, the Curator of the Royal Botanic Gardens, Kew, concurred in the view that this field was the best available situation for a botanic garden, and that a ter being properly laid out and prepared it could be kept in order by one man, if restricted to open-air cultivation as proposed. The necessary expenditure might be estimated as:—Preliminary outlay: walks, sowing grass or turfing, rockeries, garden tools, &c., propagating-frames, and a tool-shed, amounting to, say, not more than £120; current expenses—rent, wages (say, 25s. a week), manures, labels, carriage of specimens, insecticides, and other petty expenses, amounting to, say £100 annually. [Surely, far too little! Ed.] For this, with rigid economy, a very useful and now urgently required adjunct to botanical and agricultural instruction within the University would be provided. Dr. TRAIL added:—"My personal services in supervision and in endeavouring to ensure accuracy in the nomenclature of the plants, care in their cultivation, and economy in the management, would be very willingly given by me." The only hope of an early realisation of the scheme put forward by Dr. TRAIL lies in the suggestion thrown out by the Lord Rector, viz., that some public-spirited Aberdonian, with money at command, should come forward and give the useful assistance. The sum required for the endowment of the scheme is only a very moderate one—£3000 or £4000 would suffice. It is sincerely to be hoped the Lord Rector's suggestion will be acted on, and that it will no longer have to be said that so important and ancient a seat of learning as Aberdeen University lacks so important an adjunct to its teaching of botany as a botanical garden.

A CLUSTER OF APPLES.

It is not often that one sees a perfect cluster. More often than not, one or more of the infant Apples get squeezed out of existence by the encroachments of their bigger or stronger brothers. It was not so in this case; the terminal flower (in the botanical sense, not in that of the *Chrysanthemum* growers) arrived at its full development as the lateral ones. The specimen (fig. 7, p. 27) was grown in the north of Ireland, and obligingly forwarded to us by Mr. Percy Dicknell.

HOME CORRESPONDENCE.

GREVILLEA ROBUSTA.—This plant is excellent for decorative purposes in the autumn and winter if seed be sown in March in a hotbed with a temperature of 65 to 70 as a minimum, and the young plants gradually hardened before the summer is over, so as to stand a temperature of 40° to 45° minimum during the winter. I have some at the present time in 6-inch pots which are 2 feet high on single stems, and 2 feet in diameter of foliage, the latter being good to the base; it would be difficult to find more useful foliage plants, equally pleasing in character, that will stand a similar winter temperature. Previous to this season it has proved difficult to raise in quantity from seed, but I am very pleased with the last trial; possibly our seedmen have discovered quicker means of transit, or an improved system of packing. Like all the members of this family, it likes a fair proportion of peat or other vegetable matter to grow in. *H. H. Dives.* [Do they not bloom with you? Ed.]

FLAVOUR IN APPLES.—Having read the remarks of "A. D." in the issue of the *Gardeners' Chronicle* for December 19, p. 762, I thought that I would send a few fruits of Apple called in this neighbourhood Spice Pippin or Brown Spice for your opinion. It is not a handsome fruit, but its flavour, I venture to think, places it in the front rank as a winter dessert fruit. The tree that these came from is at least seventy years old. [Mr. A. P. Barron to whom we showed the fruits, remarks as follows: "The fruit is very highly flavoured, sweet and good. Flesh a little hard and dry perhaps." Ed.] *Thomas Fiach, Giftords Hall, Stoke, Colchester.*

MARGUERITE-CARNATIONS.—These are fast becoming favourite flowers, making satisfactory returns in abundant bloom when well grown, and the strain is a good one. I noticed recently a truly fine healthy growth in one of the greenhouses at Waterbury Place, the seat of Alderman Davis, M.P., under the care of Mr. Neame, and not only were the plants well grown and with a wealth of bloom open upon them, but the size of the flowers was good, and they were double and fragrant. The seed, I am told, was sown early, and half of the plants (250) were grown on in pots, and the remainder planted outside and lifted in the early autumn months. Those which were in pots had been always much the earlier lot to come into bloom, while those taken up and potted, although they were lifted in the autumn, gave equally good results. There were very few single flowers amongst them, and the "grass" was stout and robust. *H. Markham.*

THE PEACH OUT-OF-DOORS.—Occasionally we find some able grower of hardy fruits giving his experience in these columns with the Peach, but they seldom touch the subject I am anxious to have their views upon, namely, whether the Peach should be secured with fast set fixed wires or with nails and shreds. Now, I consider this an important matter, especially to a gardener on first taking charge of a garden, when he is probably anxious to reduce the amount of labour expended in one direction to enable him to spend it in other directions. Only those charged with the work have any idea of the number of days required by two men to loosen from the wall, wash, and renail the trees on a Peach-wall of, say, 50 or 60 yards long. I possess three of the most useful gardening books, *Thomson's Gardeners' Assistant* (revised edition), *Nicholson's Dictionary of Gardening*, and the latest work on fruit culture, viz., *The Fruit Grower's Guide*, but in none do I find instructions for wiring walls; so one must conclude that the practice is not a general one. I know that the trees derive more warmth from the wall when nailed than when they are fastened to wires, as it is almost impossible to get the wire quite close to the wall. One would not advocate the use of wire in the colder parts of the country; but in the warmer south and western counties a wired wall would be unobjectionable, except, perhaps, on the score of expense. Such a wired wall will be the better in a very few years, coming in that respect favourably with nails and shreds, which cost much money every year. I would like to have the opinion of growers who may have their Peach-walls wired out-of-doors whether they get such good results as when nailing is practised? *James Mayne, Birtou, Devon.* (The wires should consist of thin ungalvanised iron fixed vertically, 6 inches apart, by means of eye studs driven into the wall nearly flush with the eye. This allows a space of, say, the diameter of the eye, one-tenth to one-eighth of an inch, which is ample, for passing behind it the bastor willow ties, and really allows the branches of every size to touch the wall as closely as they were nailed. The cost of the studs for the ends is a little more than that of common cast nails; and that of the studs used intermediately is rather less, these being smaller. Such wires do no harm to the shoots or fruiter, last a quarter of a century, are easily managed when broken, and render the use of nails unnecessary. Ed.)

GROS MAROC VERSUS GROS COLMAN.—Would you kindly permit me to "dispute a short piece" on the Gros Maroc versus Gros Colman controversy, not that probably I have anything new to dilate upon, but my experience of Gros Colman dates from some thirty years since, hence I claim to know a little about this variety. At the outset of my horticultural career as an amateur, being then hardly out of my teens, I took to Grape-growing as a hobby, and for exhibition. I then grew something like twenty-eight different varieties, and amongst them Gros Colman was one. That particular Vine was presented to me by the late Mr. J. Pond of the Vineries, St. Lawrence,

Jersey, and was grown from a cutting from probably the first and original Vine of the variety then existent in the island. This was planted by Mr. Fennimore (the original proprietor of these vineries, and one of the pioneers of Grape and market-growing under glass in the Channel Islands) over forty years ago. The disagreeable early flavour of the variety as grown by me was the great drawback, as its imposing and noble appearance on a show-stand was the admiration of all. It never entered my head at the time that allowing the bunches to remain on the Vine after colouring would improve the flavour, but such is undoubtedly the case, and is the grand secret. In former years flavour ruled the day in the estimation of Grape connoisseurs, not so unfortunately in the present day, when a change has come o'er the scene—everything now in the fruit line must be fine and large. Quality is entirely a secondary consideration. There is no doubt, however, that the culture of Gros Colman is better understood, and the longer the bunches are left on the Vine, even after colouring (which process takes about three months to perfect), the better the flavour. Having also noticed it worked on Black Hamburg, I can vouch for its superior excellence when so grown. Some three years since I was assisting to judge the Grape classes at a local show, and I then tasted a sample of Gros Colman, which, to my mind, was as good as anything in the Grape line, barring Muscats, that could possibly be. The bunches in question were grown by Mr.

FIG. 7. A PEACH: CLUSTER OF APPLES. (SEE P. 26)

Booyer, gr. to Mrs. Drayn, Highfield Vineries, St. Saviour, Jersey. The berries were not over large, but the colour and finish were good. I have invariably found that large (enormous, I may say) berries, measuring about 4 inches in circumference, such as are often witnessed at shows, are deficient in flavour. This, I think is due to overfeeding. Now as to Gros Maroc, I grew it for several years, but discarded it for its shy-bearing propensities; for I found, that to produce anything like a crop, the long-rod system had to be resorted to, or the spurs had to be left long, some three or four eyes. Mr. M. Temple states that he has grown Gros Maroc for years, and always found it crop capably. This appears to me strange. May be the northern clime suits it better than these more southern regions. As regards the point at issue, that which is the better-flavoured Grape of the two, I opine, that eaten at the same stage, neither being allowed to remain on the Vine after being fully coloured, Gros Maroc, without a doubt, is the better flavoured. Moreover, it colours in one-half the time, and hence is fit for table much sooner; but as a market variety, with the present craze for size and appearance, as also for cropping, commend me to Gros Colman, despite its liability to spider. *P. F. Le Sueur, Jersey.*

GRAPE VINES.—In answer to "T. S.'s" inquiries at p. 733, last vol., as to what early varieties of the Grape-vine are likely to succeed when inarched upon Gros Maroc or Gros Colman, if any late ones have been known to succeed when inarched upon Black Hamburg, and also as to whether Buckland Sweetwater is useful as a stock for other varieties? I am enabled to inform him that Black Hamburg is the most

likely early Grape to succeed on the above-mentioned stocks. Madresfield Court would also do fairly well grafted on the same stocks so far as size and the colour of berries are concerned; but with a prospect of the flavour of both Black Hamburg and Madresfield Court being impaired by the influence of the stock. Gros Maroc and Gros Colman I know by experience not only do well inarched on Black Hamburg Vine, but the flavour is improved thereby, and I see no reason why Black Alicante, Ashwick Seedling, Lady Downes, Gros Guillaume, and Mrs. Pince's Black Muscat should not do equally well when worked on the Black Hamburg stock. Madresfield Court might also be employed as stock for late black varieties of the Grape-vine, with every prospect of putting more flavour in the fruit. As a matter of fact, all black Grapes, excepting Madresfield Court, Muscat Hamburg, and Mrs. Pince's Black Muscat, are improved in flavour by being engrafted or inarched upon the Black Hamburg Vine; and the same remark applies with equal force to all white varieties when worked on the Muscat of Alexandria stock. Foster's Seedling, Golden Queen, or Mrs. Pearson might be engrafted upon the Buckland Sweetwater Grape-vine. In the matter of engrafting one variety of the Grape-vine upon another, it is always well to first consider what character of fruit the result of such a union or unions of stock and scion will produce. I once inarched two young shoots of Gros Maroc from a pot-Vine—one upon a variety I had sent me from Malta, and the produce of which (purposely obtained the first year after planting) was very poor in every respect; and the other upon an adjoining Black Hamburg. The Grapes resulting from the former union were so altered by reason of the influence exercised on the scion by the foreign stock, as to be unrecognisable by several Grape-growers, who saw them side by side, both on the Vines and in the Grape room, with the produce on, and obtained from the Gros Maroc, which was worked upon the Black Hamburg, and which was easily recognised. The berries were, however, not quite so oval as those produced by the Gros Maroc Vine on its own roots. I need hardly state that the said foreign stock and scion were rooted out of the Vine border forthwith, whilst the Gros Maroc on the Black Hamburg stock has borne crops of good Grapes ever since; although, as stated on p. 725, it evinces a disposition to produce insufficient bunches for a crop each succeeding year, in the course of five or six years' full cropping—some years more, and others less. The above-mentioned facts of thoughtless selection—or rather attempt to make use of the Grape-vine as a stock for one desired to be increased, has not been forgotten by the writer, who communicated the facts to the *Gardeners' Chronicle* at the time. *H. W. Ware, Lime House, Rotherhithe, Essex.*

CYCLAMEN AND ITS CULTURE.—I have noticed during the past few weeks many notes in the *Gardeners' Chronicle* respecting the behaviour of the Cyclamen. If plants are wanted for exhibiting at spring shows, such as the Royal Botanic, Crystal Palace, &c., the seed, which must be obtained from a good source, should be sown quite eighteen months before the plants are wanted, and August is the best month for sowing. Sow the seeds in pans of 9 or 10 inches diameter, half filled with crocks, in a compost consisting of three parts fibrous loam, free from wire-worm and other pests, one part of leaf-mould, and a small quantity of silver sand. Place the seed pans in a pit having a temperature of 70°, and when the first leaf is visible, that is in about one month from time of sowing, they should be pricked off into other pans or pots, care being taken to afford them plenty of drainage. While in this stage, the stirring of the soil to aerate it will help the plant on. When the third leaf shows, they are then ready for 5-inch pots, and by the time they have reached this stage, the sun will be getting rather warm about mid-day, when the plants should be slightly shaded, as if exposed to the sunshine the foliage will become soft. In fact, the plants will be seriously checked. After they have been potted in 5-inch pots, the temperature may be reduced to 60°, with plenty of air afforded in fine weather, and at this degree of warmth they may be kept till they are wanted for flowering. Re-potting may be continued till they come into 8 or 10-inch pots. It will then be time to let them throw up their flowers. During the growing season, they will require fumigating at least once every week to destroy green fly and thrips, for if these be not kept under the flowers will be deformed. In the majority of cases of cheap cyclus in our getting flowers of good quality, it is because these plant-pests are allowed to cripple the young buds. When the plants

are put into their flowering-pots, a little soot-water added once a week is beneficial. If not quite forward enough by the time they are wanted, they can be put in a temperature of 75°, with plenty of air when the sun is warm, for if the air is damp at that degree of warmth, the buds will damp-off. If wanted for marketing purposes, the above treatment will ensure the grower some first-class stuff, only the pots will not need to be larger than 6 inches. I will give a full account on the growing of seed, and old bulbs, in some future issue. *Charles White, Storeage, Herts.*

CYCLAMENS AT NOSTELL PRIORY.—Judging from numerous letters which have appeared in the *Gardeners' Chronicle* about Cyclamen blooms failing to open, it must be a common thing. The best grown lot of Cyclamens that I have seen lately is growing at Nostell Priory Gardens. Mr. Easter, the gardener at that place, told me, on enquiring how he managed the plants, that the seeds were sown in the autumn of 1895, and kept gently on the move during the winter, with shifts when needed, and finally coming into 5 and 6-inch flower-pots. The compost used consisted of good loam, leaf-mould, and a sprinkling of sharp sand. In June the plants were placed in a cold frame under the north wall for the summer. They are at present standing in a greenhouse where a temperature of 45° to 50° is maintained, and nothing more satisfactory could be desired. *J. T.*

CHILIAN BEET AS A WINTER DECORATIVE PLANT FOR THE GREENHOUSE AND CONSERVATORY.—At our local harvest festival we helped to decorate the church by potting up a number of plants of Chilean Beet. Being only intended for temporary service, small pots were used, and the show was gorgeous; when no longer required, they were brought back for the sake of the pots, but as they showed no signs of fading they were distributed about the conservatory, where they still remain, and where they are likely to remain, retaining their colouring so perfectly that we have to partially hide them behind the greenery to prevent them spoiling the effect of the comparatively insignificant Roman Hyacinths, &c. It is probable that these would make first-rate market plants for decorative cold passages and entrance halls, and we would have tried the experiment on a larger scale this winter, but for the fact that we were so pressed by our friends for them that we had to give three-fourths of our stock away, and refuse a great many more applications than we have exhausted our stock twice over. *Thos. Fletcher, Grappenhall, Cheshire.*

GROS COLMAN GRAPES.—I was much pleased to see in a recent issue a paragraph from Mr. Bates, agent the above Grape, weight of annual crop, &c. I should be obliged to Mr. Bates, as would other comparative youngsters (I feel certain), if he would give us a description of his method and system of culture, not only of Gros Colman, but also the other varieties grown at "The Hayes." Knowing the very limited borders (all inside) at that place, I feel sure Mr. Bates will somewhat surprise Grape-growers at the results he has for some years obtained, not only with Gros Colman, but also with Muscats and Lady Downes. The two latter have been grown in borders of about 4 feet 6 inches by 2 feet 6 inches deep, if I remember rightly, and with such success that they have obtained prizes at Trentham and Salop annually I believe. I should like to ask Mr. Bates, if he considers outside borders necessary in any case, and for Grapes of any season? I must apologise for diverging, but seeing Mr. Bates has emerged into print, I take the opportunity to ask him for some further revelation as to his ways and means of attaining such results, not only as regards "Gros Colman," but other Grapes which have been exhibited by him. *Cirestria.*

HUYSH'S VICTORIA PEAR, ETC.—In a recent issue of the *Gardeners' Chronicle*, at p. 11, "J. C." writes:—"Huysh's Victoria and Bergamot Pears are grown here as standards, and are very prolific." This is very indefinite, as I many gardeners would like to have, in this case as well as in all others, something precise as to the locality meant by the writer. *J. E., Nostell Priory Gardens.*

A PERENNIAL TOMATO-PLANT.—Referring to Mr. Joseph Meredith's letter concerning the fruiting of a Tomato-plant for several years in succession, I may remark that in the autumn of 1889, I was having a house 65 feet long cleared of Tomato-plants, and one plant, about in the centre of the house, appeared so vigorous that I decided upon leaving it untouched where it stood. The house was forced during the

winter, and the plant made good growth, and the shoots were trained right and left to the wires, till the greater portion of the roof was covered with them. I began to cut ripe fruit in the month of April, and the plant continued to fruit the whole of that season, several hundred lbs. being cut from it. This particular plant was a seedling of mine, similar in character to the true type of Hackwood Park Prolific of the present day. Grown in the ordinary restricted manner, the blooms failed to set satisfactorily, but when allowed to ramble at will close to the glass they set well. The fruit was round, and the entire crop of them on this plant came of a marketable size. It was considered by those who came to see it a great curiosity. The plant possessed a single stem. *P. F. L. Sauer, Jersey.*

FRUIT-GROWING IN THE METROPOLIS.—What very fine examples of fruit have been exhibited recently from gardens in the metropolitan area! In illustration may be mentioned the exhibits of that painstaking young gardener, Mr. W. Taylor, at Tewkesbury Lodge, Forest Hill, and the many successes he has achieved, notably 1st in the Champion Class for Grapes at the Royal Horticultural Fruit Show at the Crystal Palace, 1st in Champion Class for Grapes at the National Chrysanthemum Society's Jubilee Exhibition, last year, other prizes, not forgetting the grand collection exhibited at the November meeting of the Royal Horticultural Society at the Drill Hall, James Street, Westminster. The Peaches and Grapes exhibited at the July Meetings of the Royal Horticultural Society by Mr. Kelf, gardener at St. John's Villa, Regent's Park, were fine specimens of high culture, and deserving of all praise. So that with all the disadvantages attendant on gardening in London, the fruit grower at least can hold his own against the more favoured provincial cultivator. *John Curville, F.R.H.S.*

HOME-GROWN AND AMERICAN FRUIT.—In "A. D." remarks on the above subject in a recent issue there is a great deal of truth, and growers should remember and put his suggestions into practice. The colour and clearness of skin in fruit, always appeal to the ordinary purchasers, who sometimes say they have no need to do so. One large fruit-grower, an acquaintance of mine, says there is more in the colour and appearance of the fruit to recommend it than in flavour, the latter being sought for by the few, but the people in general regard most the colour and price. It is not very enticing when the would-be buyer sees a mixed lot of Apples or Pears, some large, some small, some ripe, others half-ripe, or may be rotten, tumbled anyhow into a basket. It is true we still have something to learn from the foreigner in gathering, grading, packing and marketing fruit; and I believe that such can be made by selling good fruit well packed. *S. H.*

WOOD-ASHES are used here for many purposes in garden and field, and are I consider, good fertilisers. We use a good deal of wood as fuel in one place every day, the fire being on an open hearth, and long and large pieces of wood are burned, the fire-place being 6 feet wide, a circumstance that saves much labour in sawing. At this season of the year we employ a small quantity of coal (as sometimes the wood is green), unless we have been up the chimney to dry, wood is then chiefly used, but it is no detriment to the bacon to use a little coal. We put pieces of wood 5 to 6 feet long, and 6 inches diameter, on the fire, so there is much saving of labour, time, and of waste, compared with what wood prepared for a grate would require. It may cause perhaps some doubts in the minds of some as to the size of the fire-place, but by being built some hundreds of years ago, when wood was the only fuel used, it was very convenient to feed the fire with long pieces. *J. C. Blebyrie.*

LATE CHRYSANTHEMUMS.—The following late-flowering Chrysanthemums amongst many others may be depended upon to give satisfactory blooms about Christmas time and the New Year:—Golden Gem, J. S. Bibbens, L. Isere, W. W. Coles, Lady B. Sanders, Peter the Great, Ethel, Lord Brooke, Geo. Daniels, Marie Hoste, Duke of York, Cecil Wray, W. H. Lincoln, Julie Lagravre, President Bord, Madame Carnot, Silver Cloud, Mr. W. G. Whittle, G. C. Schwabe, Primrose League, H. Neve, Miss A. A. Haggis, Mr. W. W. Clarke, Fair Maid of Guernsey, Inter-ocean, Grandiflorum, Princess Victoria, A. O. Adams, and the single variety, Mrs. Langtry. The above varieties were very good here on January 1, and some had been used for Christmas and church decorations; Peter the Great, Ethel, and Julie Lagravre are excellent. *B. Wailes, Birtwall.* [Accompanying this communication there came a box of

blooms representing a number of the above varieties. At such a season their usefulness is beyond doubt. Ed.]

HOW TO CLEAN LAND OF COUCH-GRASS.—The best, cheapest, and quickest method to get rid of this noisome weed is to steam cultivate the land when dry, doing it both ways at about 5 inches deep, or more if this be required, and then well drag it first with coarse drags, and gather up into heaps and burn, and then harrow again with finer well harrows, and afterwards harrow it as often as possible, and continue to burn all that can be collected. After you have got it clean, give a guinea per pound for what remains. I planted Barley in May after cleaning the land, as much as time would permit as it was getting late, and I had a good crop after, only ploughing, dragging, and harrowing the same. The piece was divided into two parts for experimental purposes, and this was laid after being cultivated in June, and in the manner stated above, it being full of what the cars produced. The other half of the piece was sown and got off the land before seeding, and used as litter, burnt and in other ways destroyed. The land was then ploughed and planted with Wheat, and this pronounced by agriculturists to be the best piece of Wheat in the neighbourhood; and being close to the Queen's highway it was open for inspection and criticism, as this is the age for that. This piece of land was full of Couch-grass, just like a hayfield after being dragged. I am sorry to say that I was insane enough to take to several acres of land adjoining my own, and its condition was similar to the piece, and worse than I thought; but I have mastered it, and trust to have a good field when I thrash out the crop. My own land gets the pest from the adjoining field, but by giving one guinea per pound for it you can cure it. The question is asked, does land deteriorate? My answer is, Yes, by starvation and poor culture; and No, if fed off and kept clean. My own land has been planted with corn ever since I can remember, viz., Wheat, Barley, and Beans the same every third year, and I never heard my father say anything different, never followed or platted with roots, and only treated as above. I am in my 60th year, and my father was aged 78. *J. C. Blebyrie.*

THE WEATHER IN SCOTLAND.—In the north the autumn was one of the most sunless I ever remember. Although the weather was comparatively mild, fruit trees were long in casting their leaves; but fruit-buds appear to be abundant. Mild weather at that season is not favourable to the ripening of the wood, or conducive to fruit-bearing the following year. Our thermometer indicated 52° on New Year's eve. *M. Temple, Carron, Strathgairn.*

SOCIETY.

THE POTATO TERCENTENARY.

(Continued from p. 13.)

THE RAISING OF NEW VARIETIES. Mr. ARTHUR STODOL, in speaking on this subject, said:—

In attempting to effect an improvement in the cultivated form of the Potato, it is found that the old rule "like produces like" does not in this case hold good, and the development of the Potato being restricted by such a limitation, it is probable that our present supply would resemble in character that of which Gerarde wrote three centuries ago. I need scarcely remind you that Potatoes are more numerous of under-ground and thickened, in which starch is stored up in smaller or larger proportion, according to the characteristics of the several varieties. Like other underground stems, the tubers possess buds or eyes, from which, by fresh shoots, the plant is capable of redevelopment. It will therefore be obvious that improvement by selection of the tubers is impracticable. Anyone can demonstrate this by planting a tuber which from any cause may be misshapen. The produce will revert to the uniform type of the variety to which it belongs. The only modification of this rule I am acquainted with is in the cases where all the tubers of one plant show a uniform divergence in character, either for better or worse, accompanied by the foliage by a corresponding divergence from the type. When this is so it is possible that, by planting these tubers and continuously selecting the plants during growth, a slightly different Potato might result, as in the case of some types of the Ashleaf section, which are dwarfier and more compact than others, and are raised outside the Ashleaf class, however, I know of no such instances. A really first-class seedling Potato is not likely to degenerate so quickly as is generally supposed. If degeneration sets in soon after its introduction, it merely proves that the variety is one which ought never to have been brought to public notice.

POTATO DISEASE.—At the present time the Potato fungus is fought by two methods, differing fundamentally in principle. By the system originated in France an effort has for some years been made to fortify the plant against the attacks of the Phytophthora, or Peronospora. The crop while growing is either sprayed with the liquid Bordeaux Mixture or with a similar mixture of lime and sulphur. In some a powder consisting of similar chemical constituents. In the elaborate series of experiments conducted in conjunction with Professor GIBBERTI, of the University Extension College, Reading, in 1895, we found that in the first and second crop varieties no advantage was gained by spraying. The third crop finished the series, and distinguished itself by the plants, and the dressing did not appreciably lengthen the period of growth; in fact, there was an actual loss on the sprayed plots. During the past season—1896, these experiments were continued, with the result that in the case of a late main crop Potato there was a gain of 6 wts. 5 lbs. per acre, but exactly the same spraying applied to the White Elephant Potato gave a loss of 12 wts. 2 lbs. It is, therefore, a question whether in the majority of cases there would be sufficient additional weight per acre to compensate the grower for the somewhat laborious task of spraying his crop three times during the season. In such a case, however, point out that the soil of the experimental grounds is very light and porous, and that the climate is dry; and I consider these facts account for the different results obtained where spraying has been carried out on heavier soils under similar climates.

In other systems of attempting to render the Potato crop less liable to disease by raising and distributing seedlings having a robust constitution, capable of resisting the attacks of the fungus. In this system I have for years taken a deep interest and it occurred to me that it might be possible to succeed in popularising this branch of experimental work, especially if aided by the following illustrations. Various cases in the history of the experiment I have conducted. To these a few examples of related species are added.

Those who attempt to raise seedling Potatoes must possess abundant patience. Like many other species which are not habitually multiplied by seed, the Potato has a remarkable tendency to revert to the wild form. It may be necessary to examine thousands of plants before a single seedling is obtained, one which is really worthy of a place among the better varieties already existing. M. de VIGNON, who says that in the raising of seed Potatoes has been proceeded with in a somewhat haphazard manner, while we have followed a more systematic method, seeking, especially, richness in starch, excellence of flavor, power of resisting disease with little tendency to develop blight. Unfortunately, he says, they are not always able to profit in France by our progress, because the French have a marked preference for Potatoes with yellow flesh, whereas with us for many years past there has been a preference for white-fleshed Potatoes. Hence, even the celebrated Magnum Bonum, which my house had the honour of introducing in 1875, after a brief period of popularity in the Paris markets, has been almost abandoned as a table variety, on account of its flesh being too pale in colour. M. de VIGNON remarks that in Germany considerable attention has been given to the raising of seed Potatoes, more particularly with the object of obtaining varieties which are specially adapted for the production of alcohol and starch.

"ENGLISH AND IRISH POTATO CULTIVATION AND TRADE" was the subject of a lecture by Professor MALDEN. He said,

There are three Potato growers, there are several conditions which hold good: (1) A warm, dry, well drained soil, in a healthy state of fertility; (2) liberal manuring; (3) sound seed; (4) a change in the stock of seed; (5) varieties which possess disease resisting properties; (6) varieties which are suitable for the market; (7) deep and thorough cultivation; (8) careful seed selection, in which all diseases are properly avoiding. There is, undoubtedly, great waste in attempting to grow them on a large scale on land not suitable for them. If necessary drives, and Potatoes must be grown, the unfavorable soil should be rendered, so far as possible, similar to the deep but friable soils on which they prosper. This, of course, must be done by irrigation, and the water, if used, should be little if drainage is required. There can be no doubt as to the advantage of deep cultivation. The roots of Potatoes like to penetrate deeply. During the past two years my own observations have led me to think that a very large portion of the loss in the potato crop is due to the plants, to a great extent, the feeders. We have had two opportunities of watching the effect of drought on our hot gravel soils, under no moisture for which is obtained from shallow springs, and these springs have completely failed. On both occasions (1894 and 1895) the loss was about 50 per cent. In some of the best crops as might have been expected; but when the rains have been heavy enough to go to the roots, there has been a rapid growth. I am speaking of instances where, through prolonged drought, growth had not only stopped, but the plants were withering. The greater the depth of drainage, the more likely will be the plants to suffer in a dry time, and the water will excessive moisture be drained from the tubers; while, of course, the roots raise more easily for food as well as moisture.

The Potato is a gross feeder, and requires a considerable amount of nitrogen to make full growth. If, however, nitrogen is largely absorbed by the soil in the form of ammonia, the very heavy leaved and small tuberous varieties of the bog land is produced. Good quality is obtainable only when there is sufficient lime, potash, and phosphoric acid available. Farm-yard manure is a good dressing

for most soils, while, on good low lands, large quantities of superphosphate of lime—used as much as half a ton per statute acre—are employed very satisfactorily. The subject of manuring is, however, one which would occupy a whole paper, so it is useless to attempt it here.

The Potatoes which it is advisable to grow are those which sell readily. During the past few months it has been repeatedly pointed out to those who grow Potatoes to adhere to their prejudices and not to adapt their export manufactures to suit the taste of those to whom they hope to sell. When a people have become accustomed to a particular type it takes a long time to wean them from it. The Englishman will not be likely to give up his old ideas, he will want. The Englishman tries to force his own ideas down their throats, and they will not have them. Is there not something of a similar nature with regard to the Irish Potato grower? The Irish people have acquired the taste for what is regarded in England as a coarse-flavored Potato. An Englishman wants his Potato to stand as his butter. The Englishman is probably a bad judge; but at the same time he is going to buy what he fancies, and the consequence is he will only have what is mild. He wants a white-fleshed Potato, while the more popular Irish Potatoes are yellow-fleshed. It is not surprising that the French who grow in France the white Potato is more or less despised. If, therefore, it is probable that the Irish man is right, and where he grows for his own consumption he is very foolish not to grow what he likes. If he is satisfied with growing merely for his own consumption, and something over for the pig and chickens, the matter will not be here; but if he is to sell, he should stick strongly to what there was to be a great advance in Irish farming in the next future. Straws show which way the wind blows, and I saw many straws which made me come to the conclusion that more skill and energy were going to be put into the raising of the Potato than has been possible hitherto. If more be produced it must be exported, and the great importing country has alongside of it, and there is nowhere else where the produce can be better placed than in England. To do this the Irish farmer must cater for the special market, and these he grows for this purpose must not necessarily be of the kind that supports the French market. If he is to be by the customer he hopes to obtain. It must, in fact, learn what is popular in England, and lay himself out to produce it.

I found when in Ireland that an idea prevailed that the English do not like a mealy or floury Potato. This is a mistake. The highest prices cannot be obtained unless the Potato cooks dry. These deep-seated Potatoes so popular in Ireland are not appreciated in England, where far greater variety in the methods of cooking, in many instances necessitating the peeling of the Potatoes, is practised. It may be right to cook them in their skins, but Englishmen are not prepared to do this, and for the most part, in cooking, they will not put on a waiting Potato. The Englishman does not buy them because his wife says he is not, and if the wife lets them pass, the cook who has to prepare them will not. The modern domestic would rather cut the whole top off them than pick each eye out separately.

Whilst Irish growers have been sticking to their prejudices and have lost one market, which from the favorable nature of the climate they ought to have commanded, thanks to the early new Potato trade which has been seized by Jersey, the Canaries, Malta, Egypt, and other countries having a mild climate; but Ireland grasped the situation it has made it some of these countries would not have been markets at all. Such varieties as Myrtle's Ashland, Sharpe's Victor, Ode's Favorite, the Puritan, Market Favorite, Supreme, Triumph, and Windsor Castle are necessary if this trade is to be obtained. It will be necessary as a rule to grow these near to shipping places, as the high rates and inconveniences of the Irish railway systems are to an extent prohibitive. If a good business is established, means for collecting and transporting would doubtless be organised. It is with all classes of Potatoes necessary to market them in good condition, but it is more particularly so with earlies. They must be well selected and properly packed. The greater portion of the export trade is usually in late varieties. Whether the market sticks to the Champion for its own consumption is a matter for the Irish to decide; it is, however, useless for export to meet the better and therefore more paying markets in England. If Irish Potato culture is to be improved with the idea of growing to export, the Champion and its immediate similar coarse varieties must be left out. The Beauty of Bath is a degree better than the Champion, but in accordance with English ideas it is second rate. I was somewhat disappointed when it is tried with about twenty other kinds, as it was the earliest to disease this year. Except for this it appeared to be the best of the lot, and it would not have been so, had prices. The King, which does well for the Irish early trade, is not well suited for export, for better Potatoes are obtainable at the time these are ready to come in.

The past two hot, dry seasons have been distinctly favorable for the growth of the Champion, and have done much to bring it up, and in regard to its value. It is well during the dry seasons which have prevailed late is in itself a source of danger. It has become considered to a serious extent when wet summers prevail again. Chances do not change materially. The sense of security which the past few years have produced should not lead the grower into a state of dormant inactivity. There will be no resting if he has not secured it. The Champion is not safe enough to trust to. In its early vigor it practically sold itself in its deteriorated state it is no longer safe, and it is well to take it on the first occasion when a season favorable for the development of disease comes. While it is so popular for culinary

purposes, and in dry seasons crops satisfactorily, I do not advise its absolute elimination, but I regard it as being a careless and willful act on the part of growers to place practically their existence on its growth of one variety of Potato, when by almost common assent that variety has become unreliable and is no longer reliable. There are three ways in which the grower may improve. By good cultivation, a selection of varieties which are the best of the best, of resisting disease and such as command good prices, and by spraying. If he can be got to see the folly of trusting almost entirely to one variety good as that variety proved itself in the past—let him feel sure he will conduct his Potato grower on similar lines, to those of a farmer near by, who has Potatoes not popular in Ireland; though why they should not be so in dry seasons I do not quite understand. I am aware of the great tendency all but the newest introductions have to produce second growth, and therefore inferior quality, when from any cause they receive a check in their growth. We have largely given up growing late Kidneys because of this tendency to second growth, as our farms are in a particularly dry climate, and the soil is largely a bad, burning gravel, so that in hot seasons they are liable to receive a check. But in ordinary years the tubers do not hold. The French, who have made the recommendation these late Kidneys which have been sufficiently long before the public to have proved themselves, but not long enough to have become afflicted with the weakness intended to old age. Although scarcely a kidney, there is no question but that the new Potato Date, which in its short career has rapidly become a favorite, and which, in the long and alongside of it I would put this Farmers' Glory, whose weakness is its strength; for if it has a market falling, it is its robustness, which, after all, is generally a virtue in a new variety. Among the rounds I regard the White as being the best, wet season variety, for it appears to be well in wet, and our view is that the grower where a large quantity of wet fell when showers were few in most places, yielded seventeen tons per statute acre. Among many varieties, were thirty, which we grew this year. It was the last to be affected by disease in the wet period of the latter part of August, and the first to be affected in the latter part of September, when other varieties were blackened. The round pieces still practically free from disease. I regard it as highly important to grow a selection of varieties embracing those which flourish best in dry seasons, and others which are best in wet years, as their excessive losses may be avoided to a great extent.

In these days of spraying it is advisable to look to grow varieties which produce such full London that the grower cannot be worked into them. A change of seed is always advantageous, though, when it is taken from a climate differing widely from that to which it is transported, it may give a disappointing result in the first season, and, in fact, may seem to be some of its more marked characteristics; but after acclimatization has taken place it attains its normal condition. This is noticeable not only in the Potato, but in crops such as Barley, Wheat, &c. It is not a rare occurrence to hear those who have made a change of seed say, "I did not see that I did any better by it, and I don't much care about getting any more that way." A broad and long experience, however, will definitely prove a change of seed to be really advantageous.

On behalf of Mr. A. FRIEDLAV, of Mankinch, who was unable to attend, Mr. RICHMOND read the following paper on "THE RECENT ADVANCEMENT OF POTATOS."

In the beginning, I believe that of those who have occupied the task, I began my career by picking a plum here and a plum there of some variety that naturally bore them, and I had a fancy for sowing the seed so obtained and watching the plants from year to year in their development—very interesting, curious sometimes, and in a sense, highly educative. I hadly did not expect to find that the plants which were of ordinary tendency of the plants to run into variety, extra-plant, in fact, no matter how you may had, all of the same variety, differing from its fellows in some particular. But the object I had in view was not the perplexing of the minds of the growers by assisting in the piling up of a perfect agony count of varieties, for I have seen many of the most successful seedling lists, dressed out in all the glory of the most misleading names imaginable. The task I have set myself was the improvement of the plant and the placing into the hands of growers, from time to time, varieties that were likely to improve them in their respective classes. Improvements by reason of their greater productive qualities, and by reason of greater hardiness that it is, greater power to resist the attacks of peronospora and other fungal enemies so ably described to you by Professors JOYCES and M. W. REESE. My experience in the sort of work I have done, and the results which it has given me, may be summed up in the conviction that it was not by this method that I was to accomplish the object I had in view. No doubt some fairly good things had been got by this method—things of chance, in which there was neither honour nor credit, and to be plain, it appeared to me a blot on my intelligence. This each one of us should have done, and should be so well understood and rationally cared for that its continued successful cultivation could be at any time a matter in which there was a doubt. However, such a case, seedling as the Victoria, the Champion, and the Magnum Bonum (my information by reason of the latter variety is overgrown) was not as was a power within the plant, if properly understood and developed, that it would place the Potato in a practically reliable position as one of the greatest food producing plants known. In the consideration of this important matter it dawned upon

my mind that it might be worth while, so far as my ingenuity could carry me, to adopt some of the methods of the most famous breeders of live stock—that is, the selection and mating of different varieties, and to make note of the results, and thereby discover the best lines if there was anything in the ideal on which to proceed to build up the Potato on which I had set my mind. The fascination of the work was on me, and a few years later I met the happy possessor of the Bruce Potato, which went far to raise my hopes and send me along with all the determination and energy we Scotchmen get credit for, and are so proud of.

The Bruce Potato, as I have so often and elsewhere said, it is a true cross between the Victoria and Late Rose, but I would have you bear in mind that these, the parents of the Bruce, had been brought by years of careful selection to a higher state of perfection than I had ever seen them. There is another matter in connection with Potato raising that I have always found of advantage—that is, the making of the narrowest possible selection of any Potato that shows promise of being worth attention. For my own part, often I go so far as to reduce my stock of the most promising sort to the best tubers of the best plant in the third year of their existence, as by so doing I am convinced belongs a certain amount of the success that has been the good fortune of some of my introductions to attain. It may be of interest as showing that even after one has got a good thing that one's difficulties are not by any means at an end, to tell you some of my experience in getting the Bruce out into the world. In the spring of 1886 I had about two tons, and although I offered them to all the leading seed houses, without finding a buyer in one of them, and to all my former acquaintances, I only succeeded in selling a few cwt., although I offered them at the very modest price of 12s. 6d. per cwt. I, however, planted the remainder, and although stock had greatly increased, and all my customers of 1886 were delighted, I only succeeded in spring, 1887, to increase my sales to a very trifling extent. But they were not well spread about, as I had done a little advertising, and got them, as I have before, to local produce. In spring, 1888, my fame had filled the land, and I was able not only to sell all I had of my own, but also all the spare stock of those who had bought from me in 1886 and 1887. The success of this Scotch-American, the Bruce, made me anxious to test the value of the leading American introduction, always made in this same rigorous system of selection both before and after cross fertilisation, and I was able to offer in 1889, Lady Fife, Lady Frances, and Her Majesty Potatoes, all out of the Victoria and the White Elephant and a few others, but none of these Scotch-American crosses—good and popular as they were—quite satisfied me. I had a higher ideal than they had come to my eye. In 1890 I was able to offer Jennie Deans and Early Beauty, out of what I may call a double Scotch-American cross—first cross, Beauty of Hebron and Victoria; second cross seedling out and natural seedling out of the old Scottish Blue Dun.

Now, at this stage of my work I was indeed impressed that the Victoria, notwithstanding my care and expedients, was getting into what I may call an old age, and that, and for this reason of no further use in the raising of anything of a trustworthy character; and that though some fairly good things, such as those I have mentioned, had been got out of Scotch-American hybrids, I had become convinced that it was not through the use of these Americans that I was to get anything of commanding merit. I resolved to form an entirely new breeding stock. Whether I have done wisely I will leave those who have grown my later introductions, such as Up-to-date, British Queen, and Challenger, to say. But if I am to believe the reports of those that have for some time been conspicuously in evidence in the newspapers and journals devoted to horticulture and agriculture, and bearing altogether my own personal experience, I would have some reason to be pleased with my doings.

NURSERY NOTES.

THOS. KENNEDY & CO., DUMFRIES.

THE nurseries of this firm have been in existence for over a century, and are distributed about and around the town of Dumfries. Although dealing in all sorts of nursery stock, the staple articles are forest trees, a large number of which find their way all over the country from the orders of Her Majesty's Commissioners of Woods and Forests and the Irish Land-Commissioners. The stock of Larch, for instance, is a very large one, not fewer than 20 acres being covered with this forest tree alone. It, too, is in splendid condition, the 1-yr. seedlings being as fine as could be, and their 1-yr. seedling 1-yr. transplanted moving and furnishing as one likes to see them; while the parcel of 2-yr. seedling 1-yr. transplanted, shows that the seedlings revel in the quarters they live in. The cultivable lands of Dumfriesshire consist of fine rich loams of great fertility. Scores of men were busy at the time of our visit, raising for sending off by railway hundreds of thousands of 2-yr. seedling 1-yr. transplanted, and the plants were as clean and uniform as any that we ever saw—without

the slightest trace of disease or decay, and the wonder is, looking at such sturdy vigour in the 3-yr. old plants, why they should ever give way in our general plantations. The seed, we understand, is all "home grown," collected from trees in the north of Scotland.

Scots Pine is the next most important item in the forest planter's calendar; indeed, Larch and Scots both go together—the planter that buys the one generally buys the other. This Highland Pine, in a young state, is very captivating, the eye resting on the uniform breadth of its with delight. Where it is carefully provided for in the shape of good land, fed occasionally with manure, it will repay the outlay. The square heaps of manure in the quarters, ready to be handled with either spade or prong, indicate that the land that has borne a crop will be dressed with that which will restore its fertility before the fresh crop is taken. It was impossible to see finer 2-year seedling 1-year transplanted Scots Fir than the crop here; and then the larger 1 to 2 feet were in fine condition. The firm here, too, do not overcrowd their plants when transplanted, neither in the rows nor between the rows, and hence the plants individualise well, and when you examine the plants so managed, and those of similar age crowded together, the one is seen to be much fuller of fibres than the other.

The Corsican Pine (*Pinus Latio*) was noted in great breadth, and is doing as well as its neighbour, *Pinus sylvestris*. Its twisted needles indicate its distinctness; moreover, it is the more rapid grower. Some allege that it ought to be made a plantation by itself, as it does not mix well, overtopping its congeners. Here in the fine tilth it is quite delightful to look at from the 1-yr. 1-yr. balled to the breadth of about 15 to 18 inches high. It is one of the best of our seaside Conifers, and from its usefulness as a timber tree, where it does well, it is invaluable.

The Douglas Fir (*Pseudotsuga Douglasii*) must always command attention. Unlike the Scots Fir, it has a starved-looking appearance in youth, improving with age for general ornamental appearance, and its rank as a timber tree must depend upon the locality where it is grown. As an ornamental Conifer in uplands, where it is partly sheltered, it has no equal. It appears that the Colorado seedlings are the hardest and best, beating our native seedlings in that direction, as the latter seedlings have a tendency to grow on longer, and catch the early autumnal frosts; this is a point of considerable importance. I saw samples of them both here and also at Little & Ballantyne's, Carlisle, and noted that the Colorado seedlings were better matured as regards this season's growth.

The Spruce Firs are here in pretty plantations, and seem to stand the shade of deciduous trees of some size better than any similar Conifer. It is beautiful to look at, and comes in as one of the principal plantation trees. The Silver Fir does not appear to do so well in this locality, there is a disposition to get sickly-looking, although it is much in demand; and where it does well, as about the Duke of Argyll's estate at Rosneath, where the two largest trees exist in this country, years ago described by the writer in the *Gardeners' Chronicle*, nothing could be more stately, and the beautiful silver sheen of the branches, makes it a most desirable plantation tree.

The Crimean Silver Fir (*Abies Nordmanniana*) is a good breadth, and one of our most symmetrical Conifers up to the time it steers clear of the "loner," then its needles get discoloured and fall off, rendering it very unsightly. In a young state it is most desirable, although it will never take the position claimed for it a quarter of a century ago by some foresters as the future Silver Fir of commerce.

Pinus austriaca is always in demand, and does fully as well as any of its tribe in or about town, country, or seaside. It will always take rank as a fine screen tree, rapidly getting up; however, getting uglier and less useful the older it grows. There are quantities of it in this nursery.

Amongst the lesser fry of Conifers that are largely grown here, and seem to find a ready sale, are *Cupressus Lawsonii* in variety, the golden form is particularly

striking. Nothing seems to be more cultivated than *Retinospora plumosa aurea*, which seems to be well everywhere, and then *Retinospora squarrosa* is about the best smoke-standing plant we have in the whole race.

Among deciduous trees, we noted the Horse-Chestnut, which does splendidly, from small trees up to those 12 feet high; but, singularly enough, neither the scarlet nor the yellow will do, getting diseased in the bark, stunted, and unfit for commerce. A large business seems to be done in the common Alder, a good tree for wet land, and grown in quantities here from 2-year seedling up to 4 feet. The common Ash is growing in importance for estate work, and when in large size it is invaluable for avenues about towns, withstanding smoke, and chemical vapours generally, better than any other tree. It grows well, too, on a clay subsoil, and the firm say that they never can get overstocked with it. Hornbeam we were glad to see quantities of, as it is so useful as a hard-wood tree, not beaten in this respect for endurance, and is highly ornamental when planted for park decoration. Beech is a plant that seems to be bought everywhere, both for hedgerow and for forest-purposes.

Thorus or Quicks like good treatment, and seem to pay the better they are seen to. This hedgerow plant is always in demand, and no nursery for the last few years has had an overstock of it; consequently its value is well sustained even in these hard agricultural times. Birch is in great quantity, and in numerous variety, the weeping form of it is very noticeable, and the lots of 3 to 4 feet of the silver form covering a considerable area. The English Oak revels in these quarters, and there are many rows of Turkey Oak and a good sprinkling of the American varieties. The Myrobalan Plum, used as hedging, is grown in quantity, and the Service-tree and the Rowan, so useful in mixed plantations, pass before the eye. Limes are in quantity, from 2 to 3 up to 10 feet high and more, and are so much in demand for small places that the stock is readily taken up outside of the trade.

One of the most striking subjects for autumn and winter decoration is the Golden-leaved Willow. It is a grand distance object, and in the lines which we say of it illumine the grounds with a brilliancy without a rival. It is a straight stiff grower, and is in every way suited for the margins of lakes near running water, and among underwoods.

There is a large stock of fruit trees, particularly Apple, worked both on the free and Paradise stock, presenting a good appearance, quite free from American blight. The stock of Gooseberries is considerable, and the other smaller fruits are well represented.

There are many other plants—Rhododendrons and Roses, for instance—which we must pass over altogether. The place is in first-rate order, the whole of the subjects being properly handled, and kept clear of noxious weeds. There is no waste of space in the shape of unnecessary roads and walks, and the grounds generally, covering over 70 acres, are free and open, few, if any, protective hedges being planted, and the neck of forest trees fully exposed to the four winds.

J. A.

VARIAION IN FERNS.

THE following extracts are taken from a paper read before the British Pteridological Society by Dr. Stansfield, on "Weismann's Theory of Heredity and its relations to British Ferns." We have eliminated much of the purely speculative part of the paper, and confined the matter as closely as possible to ascertained facts and inferences from them.

"Herbert Spencer defines heredity as the capacity of every plant and animal to produce other individuals of a like kind. We are so accustomed to this phenomenon of heredity that the superficial, who always form the vast majority of mankind, look upon it as a matter of course, and as a thing not requiring to be explained. The more thoughtful, on the other hand, have for long looked upon it as an inscrutable mystery—a thing not to be explained by human

intelligence. Of late years, however, various attempts have been made to penetrate somewhat into the mystery, and of these, one of the most important is that of the German Professor, Weismann.

HEREDITY.

To put the problem in a concrete and familiar form, we want to know how it is that Ferns always produce Ferns; mice always reproduce mice, and men and women have human children. How it is that seedlings from a *Scolopendrium* are always *Scolopendriums*; that in a pure bred herd of Alderney cattle we never get a Kerry calf; that from a pure flock of, say, Black Spanish poultry, we never get a Cochinchina chicken. Again, we want to know why Alderney calves are not all alike, but on the contrary, are all different; why there are so many different seedlings in a sowing of *A. f. setigerum*, and so few variations in a sowing of *L. ps.-nuda crispa gracilis*; why the same pair of human parents will have one child with red hair and another with black. Further, we want to know why children (animal and vegetable) occasionally bear a much closer resemblance to one or other of their grand-parents, or even to some more remote ancestor, than they do to their immediate parents.

All these questions and many others Weismann tackles and answers more or less successfully. Those who care to go into the matter more fully, will find what they want in Weismann's book *The Germ-plasm*, which has been translated into English, and published in the contemporary science series by Walter Scott.

Of course the best known method of reproduction of organisms is sexual reproduction—that is, by the union of two germs; but there are asexual modes of reproduction, buds, bulbils, and cuttings. Of similar asexual forms in the animal kingdom. I may mention the parthenogenetic production of drone eggs by the queen bee, and the viviparous reproduction of aphides, or green-fly, by the imperi et insect, both of which are quite independent of any process of fertilisation.

To begin, however, with the more familiar process of sexual generation, we know that the whole of the characters of the plant or animal must in some way be capable of being packed up within the extremely minute compass of a sperm-cell and a germ-cell, and since a spore is capable of producing both sperm-cells and germ-cells, the whole of the complex characters of a Fern, say *Athyrium f. f. clarissima* or *Lastrea montana Barnesii*, must somehow be contained within the narrow compass of a spore.

The ultimate male and female elements are of course the ovum, or egg-cell, and the antherozoid, or sperm-cell. Of these, the egg-cell is very much the larger, but we do not therefore find that the offspring as a rule resemble the female parent much more than the male. On the other hand, the characters of the two parents are generally fairly equally balanced, and when they are unequal, those of the male are just about as likely to preponderate as those of the female.

The inference must be either that the hereditary substance is weaker in the large egg-cell than in the very small sperm-cell, or that only a small part of the egg-cell consists of hereditary substance, the rest being merely nutritive material. There is abundant evidence that the latter is the case. When the sperm-cell or antherozoid penetrates the egg-cell, it takes no notice of the great body of the latter, but plunges through it and makes straight for the nucleus with which it blends itself. We shall see by-and-by that there is reason to suppose—not that the hereditary substance is the nucleus or the cell, but that the nucleus contains the hereditary substance.

THE DIVISION OF THE NUCLEUS.

The growth of plants and animals consists in the division and sub-division of cells. Within a comparatively few years, it has been observed that whenever a cell divides into two, a very complicated process is gone through.

Somewhere in the interior of the cell, and generally about the middle, can be seen by the microscope a small round spot, generally of a slightly darker colour

than the rest of the cell—this is the nucleus. When the nucleus is stained and examined with the highest magnifying powers, it is found to be an extremely complex body; it is separated off from the rest of the cell by an extremely delicate membrane or wall, which, however, under certain circumstances, sometimes disappears. It is permeated by an extremely fine and complicated network of threads. When a cell is about to divide, some curious changes take place in the nucleus, and particularly in the network of threads which I have mentioned. The threads cease to be a network, and assume the form of a single coiled fibre; next, this breaks up into a number of detached pieces, which then arrange themselves in the form of a series of loops around the equator of the cell. Each of these loops then split along its whole length, as if a piece of untwisted rope had its strands separated into two thinner ropes, and the split portions are drawn gradually towards the two ends of the cell, where they join themselves together into two bundles, are followed by the rest of the nuclear substance, and form two separate nuclei. While this process has been going on, the protoplasm of the cell has been tending to collect itself around the two daughter nuclei, and by the time the nucleus has fully divided, the rest of the protoplasm is ready to follow its example, and to divide into two parts. This complicated process takes place whenever a cell divides; that is to say, it is taking place in millions of cells in almost every growing plant. To it the name of "mitosis" has been given by biologists, and it is highly suggestive of the extreme importance of the nuclear threads of which I have spoken, and to which the name of "chromosomes" has been given, because they have the property, in a pronounced degree, of absorbing colouring-matter, which may be brought in contact with the cell to which they belong. Now an egg-cell is developed from the ovary in the same way that other cells are developed. When, however, an egg-cell is fully developed or ripe, its nucleus divides into two parts; but, instead of the whole cell dividing, one of the halves of the nucleus is simply thrust outside the cell, and there perishes. The part thrown out is called a "polar body." The nuclear loops, however, in this case are not split, but simply one half of their number are removed in their entirety. From that moment no further development takes place in the egg-cell until fertilisation has occurred, and that process consists in the replacement of the lost half of the nucleus by another half nucleus, containing a similar series of rods or loops, from a sperm-cell. All this, of course, is a matter of observation and fact, and not of theory.

VARIATIONS IN FERNS.

If we come to examine Fern varieties in detail, we shall find that nearly all of them are cases either of excess or of deficiency of development in some part or parts of the plant. According to Weismann, these correspond to local inequalities in the nutrition of the germ-plasm in the parent Fern. One thing you will all have noticed, viz.: that you may sow spores of a perfectly normal Fern generation after generation without getting any appreciable variation in the seedlings. But if you once get a break—ooze get a variation, however small, from the normal type—and sow from that, you immediately get a number of fresh variations. Take Mr. Barnes' crested dilatata and montana, for example. Mr. Barnes first of all found a natural break differing comparatively little from the type—that we should call an ordinary variety. Sowing this, the result was a number of varieties much superior to (i.e., more abnormal than) the parent; doubtless along with them were a large number inferior to the parent, and probably some quite normal ones. Mr. Barnes, however, like the wise man he was, threw the bad ones away and kept only the good ones. In this way almost any slight natural variation, by repeated sowings and selections, may be developed to almost any extent compatible with life. This is explained by the first variation affecting a few only of the "ids" [elementary particles] of the germ-plasm. Let us suppose for the sake of convenience that there were twenty ids in the germ-plasm,

and that, say three of them, were so modified as to produce cresting. Then, at the next generation we get a reducing division. It might happen that the crested ids, as I may call them, might be thrown out into the polar bodies, in which case we should get a return to the normal form. On the other hand, it might happen that ten normal ids of the egg-cell might be thrown out, leaving seven normal and three crested. If this egg-cell should happen to be fertilised by a sperm-cell which had similarly thrown out all normal ids, we should get a new germ-plasm, containing fourteen normal ids and six crested ones, in which the crested character would be intensified in the next generation. I may give you an ocular illustration of this by supposing the "ids" to be represented by coloured discs.

REVERSION.

Let us now glance for a moment at the phenomenon of reversion or atavism. An organism will sometimes exhibit characters and peculiarities which cannot be detected in either of its parents, but which belonged to one or other of its grand-parents, or even to some ancestor many generations back. The explanation of this in Weismann's theory is very simple. I have already explained that the germ-plasm of an individual contains "ids," derived from a long line of ancestors. Every variety of recent origin probably contains some normal "ids" of the species to which it belongs. Mr. Drury can tell us that in raising young plants of *A. f. f. clarissima*, some of the offspring tend to run back to the normal form of *A. filix-femina*. The reason for this is that by a reducing division the germ-cells have got rid of some of the *clarissima* ids, and so the normal ids have obtained a majority and gained the upper hand. There are probably, however, some *clarissima* ids still contained in the germ-plasm of these degenerate forms, but these form only a small minority, and are consequently unable to produce much impression upon the character of the plant. If, however, we sow again from these renegades we get a fresh series of reducing divisions, and in some of these it may happen that the *clarissima* ids gain the upper hand, and so we again get a few *clarissima* seedlings from the degenerated parents, although the bulk of the offspring are probably normal *Athyrium filix-femina*.

Let us take as another example *Polypodium c. corubiense*, which produces normal fronds among the dissected ones. In this Fern the abnormal ids have presumably only a very small working majority, and so the government is apt, as it were, to be caught napping, and to be occasionally outvoted. Sometimes this defeat is so humiliating that the government resigns and the opposition takes office, that is to say, the Fern reverts entirely to the normal form. It is probable, however, that if we sowed spores from these reverted plants we should get fresh reducing divisions and re-combinations, in some of which the advanced party would again gain the majority and again take on the reins of government. I am not aware that this has been done in this particular case, because Fern-growers as a rule prefer to sow from their best plants and not from their worst. From the biological point of view, and for scientific reasons, however, it would be well worth while to occasionally sow from reverted forms and record the results.

There is a prevailing impression among Fern-growers that if we sow spores from characteristic parts of a plant, we are more likely to get improved forms than if we sow from parts which bear the particular character in a less degree, or not at all. It is a common practice, for instance, to take the spores from crested tips of fronds and pinnae, in the hope of getting improved crested forms in the offspring. I may say at once that this idea and practice does not fit in at all with Weismann's theory. According to Weismann the germ-plasm is the same in all parts of the plant, and we are therefore just as likely to get true seedlings of *A. f. f. Kalchthrix* by sowing from the worst fronds as by sowing from the best. This point can only be determined by a large number of impartial experiments, instituted for the express purpose of finding out the truth, and not for the purpose of either raising a stock of good Ferns, or of confirming our pre-conceived notions. For my own

part I have never satisfied myself that there was anything to be gained by sowing from particular parts of a frond, and I am certain that it is quite possible to obtain characteristic seedlings of a variety by sowing from parts of the frond which do not bear the particular character in question."

FLORISTS' FLOWERS.

WHEN TO PROPAGATE THE CHRYSANTHEMUM.

To those of your readers conversant with the columns of the *Gardeners' Chronicle* twenty years ago, this will be reviving an old subject, but even to them, and to our younger brethren of the spade, I hope it may be interesting; for as good wine requires no bush, neither does such a suitable subject require any commendation. To recall the past twenty years, and compare the varieties then in cultivation with those of the present day, we find none of the Japanese of 1876 now existing; while, on the other hand, those of the inbred section are, to a very great extent, still popular. But the improvements made in the Japanese section are simply marvellous, indeed, so much so that Mr. Norman Davis (who is a great authority on the Chrysanthemum), remarked to me a little while ago, "I think we have gone almost as far as we can get in improving them, and they will soon be on the wane." Well, this is quite reasonable. Have not many other species of plants had their day, and then made room for something more popular? It has occurred to me that we may do a good deal to preserve the popularity of this, the queen of autumn flowers, and as it is not the first time I have made suggestions which have afterwards been taken up with good results, I hope that my present proposals may be taken up with equal zeal, and meet with as good results. It will be remembered that when this subject appeared in the pages of the *Gardeners' Chronicle* twenty years ago, it arose from a few sensible remarks from the able pen of that excellent cultivator, the late Thomas Hines, December 8, 1877, on p. 719, where he advocates early propagation, and gives very pretty reasons for doing so. The subject was afterwards taken up by the late Mr. Hinds, who condemned early propagation, and gave reasons why it should be deferred to the end of January or early February (see *Gard. Chron.*, December 22, 1877, p. 779). This latter letter was criticised by the pen of the present writer (January 26, 1878, p. 107), and in doing so I made the following proposal:—"Perhaps it would be desirable to raise a subscription for the purchasing of a huge Challenge-cup or trophy, to be competed for annually at a meeting in connection with the Royal Horticultural Society, the victor having the custody of the cup from one annual meeting to the other, in the same way as some of the Challenge-cups and trophies are contested for at the National Rifle Association's meetings, and in addition to the cup a money prize may be awarded, the amount of which may be determined by the society. It would be a good plan to offer such a prize for twelve blooms in each section. This arrangement would admit growers of all classes, and would undoubtedly stimulate Chrysanthemum growers to the utmost extent, and prove a very considerable advantage to the society, as it would create considerable interest, and I raise the Chrysanthemum a step beyond its infant days." At the time I wrote this there was no Challenge-cup in existence for Chrysanthemums, neither did the Royal Horticultural Society take the subject up. The Kingston Society, which was the first to adopt a Challenge-cup, had just held their first show on Nov. 21 and 22 (see *Gardeners' Chronicle*, p. 663, November 24, 1877), and on November 27, 1879, their first Challenge-cup was competed for, and from then until now that society can truly boast of a grand run of success, and the society has been supported by growers who stand unrivalled in the Chrysanthemum world. It is also interesting to note that at that time the amalgamation of those societies which were the parents of, and are now known as, that influential body, "The National

Chrysanthemum Society," had not taken place, as it was not until March 1, 1883, that Mr. Cannell proposed the adopted name of this Society, and which came into operation January, 1884. The adoption of Challenge-cups at Kingston had a remarkable effect in stimulating Chrysanthemum cultivation is certainly beyond dispute, for proof of which I may instance the numerous societies which have sprung into existence, and which have in most cases established their challenge competitions with cups, &c. We also have some of the best cultivators in the Kingston competitions, and in looking up the reports of the shows held there, I find the following winners, viz.:—1879, Mr. Hardigg, Putney; 1880, Mr. Tunnington, Liverpool; 1881, Mr. Faulkner, Liverpool; in 1882, the competition was limited to these three winners, but unfortunately Mr. Faulkner died a few days before the competition came off, but his blooms were staged, and Mr. Harding won the first cup for the last time, at the same time that the second cup was being competed for and won by Mr. E. Molyneux, Swamore Park, Bishop's Waltham; in 1883, Mr. Molyneux winning again, and taking the second cup. In 1884, Mr. Molyneux was again to the fore; and in 1885 he repeated his victory, and finally won the third cup. In 1886, Mr. Gibson, of Morden, came to the front and won; and in 1887 he repeated his victory, and finally won the fourth cup. In 1888, Mr. Coombs, of Teddington, won; and in 1889 he repeated his victory, and finally won the fifth cup. In 1890, Mr. Beckett, of Sirbiton, won; in 1891, Mr. Carpenter, Weybridge, won; in 1892, Mr. Mease, of Leatherhead, won; and in 1893 the competition was restricted to these three winners, and the cup was finally won by Mr. Mease; and the first competition for the sixth cup was taking place, it being won by Mr. Neville, of Zwyford, Hants. In the year 1894 Mr. Higgs, of Leatherhead, came to the front a winner, repeating his victory the following year, winning the sixth cup. In the year now passed away, Mr. Hunt, of Leatherhead, won for the first time. This is a magnificent record of what can be done by a society determined to hold its own in the Chrysanthemum world, constituting a good example for others to copy. Only let a society offer good prizes, and a keen competition is sure to result, and where there is good competition, the public will assemble in large numbers, giving support to the society. As numerous Chrysanthemum societies have discovered who have competitions for Challenge-cups, some of greater value than others, which when won twice or thrice are finally won, it has occurred to me that if a few influential men were to join together and raise the sum of 200 or 300 guineas by subscriptions obtained from growers in general, we might then have a magnificent competition trophy. The competition might receive its start at a London show, and then go to, say, Edinburgh one year, Dublin another, Liverpool, Exeter, Birmingham, Glasgow, Belfast, and other centres in turn, and in perpetuity, adding a sum of money with the trophy each year. Such a prize ought to stimulate both employers and employed to take greater interest in our queen of autumn flowers, and so ward off the "wane" to the furthest date; and we should encourage cultivators from the provinces get into the front ranks—men who have never been heard of, and which is exactly what is wanted. We know the effect produced at Kingston by a 25-guinea cup; what, therefore, would a 300-guinea cup do? And who can say that such a trophy would not have the effect of creating county societies with trophies of their own to be competed for in their respective areas. Will the National Chrysanthemum Society or the Royal Horticultural Society take up the matter of organisation? as I feel sure such a move would meet with a hearty response from many quarters, and I should think affiliated societies would also help in the matter. The present is most opportune for getting the affair established, and so commensurate in the Chrysanthemum world Her Majesty's long reign. For some years past I have been drifting out of the ordinary course of gardening, and fettered with a multiplicity of estate duties, situated in two widely separated counties, I have consequently found it impossible to pay special

attention to any one subject in gardening, but having lately got rid of the heaviest portion of my responsibilities, I am enabled to devote a little more time to Chrysanthemums. In furtherance of this idea I shall try this year a number of novelties, and I have got amongst others Mrs. Weeks, which Mr. Norman Davis told me was about the best Chrysanthemum ever raised. I purchased five plants at the beginning of April last, and as fast as shoots fit for cuttings appeared, I had them put in, and I now possess 200 plants. I will confess that I was much disappointed with the blooms of Mrs. Weeks which were staged at the show in the Royal Aquarium, and other shows. There is not the least doubt in my mind that cultivators working on the orthodox methods of putting in cuttings at given dates in a general way, have not hit on the proper time, so as to produce Mrs. Weeks at its best. Mr. Davis told me I was too late for the finest blooms, and other growers had stolen a march on me, but I determined to make a feature of them, and found the plants I purchased failed to produce the finest blooms; but cuttings taken off in the second week of April produced the finest bloom of any I ever saw. The plants were grown in the ordinary way with single stems and one bloom, the "buds taken" the second week in August (rather late); and on plants growing in 7-inch pots, the blooms measured over 2 feet in circumference in every direction. Mr. Lyue, when at Wimbledon House on November 11, remarked, "They are the finest blooms I ever saw, and worth a long journey to see." I shall go back to Keut and sing the praises of Mrs. Weeks." Other notable growers, including Mr. Gibson, the Messrs. Alderman, Mr. Bates, and others made similar remarks. I would strongly advise those who wish to have Mrs. Weeks in her best form to put the cuttings in about the third week in March, and grow them on freely with single stems. Of the 200 plants of Mrs. Weeks which I grew, some of which were necessarily rooted late in the spring, and grown in small pots, I was more than satisfied, and had them in bloom till Christmas. Of the other forty varieties of novelties of 1896, that I cultivated in 1896, I shall be very pleased to record my experience if at all interesting to your readers. *J. Otterhead, Wimbledon, S.H.*

WORTH PARK, SUSSEX. THE RESIDENCE OF MRS. MONTEFIORE.

THIS is distinctly a fine place, splendidly kept and at once a credit to the owner and her gardener, Mr. Glen. It is pleasant to visit places where wealth is, because, if with it there be joined a high appreciation for gardening, then is it seen in its finest and most attractive aspect. It is just this sense of plenty, and almost of sumptuousness, which gratifies the visitor to Worth Park, because everything is so well done. The lodge-entrance is but a quarter of a mile, or hardly so far, from the well-known Three Bridges railway station. There is at the first evidence in the broad, hard, well-kept carriage-road that something good lies beyond, and although the first aspect is that of openness, yet very soon the scene is changed to other surroundings, and the road runs up a gentle incline for perhaps half a mile, through fine but informal borderings of trees that are in this respect far more pleasing than the finest of straight avenues; whilst large bush Rhododendrons add in the grass margin beneath. There is at the highest part a couple of rows of young Limes that rather jar upon the hitherto pleased senses; and all the more so, because thus early, for it is but September 24, whilst nearly all other deciduous trees are so green-leaved, these have their foliage brown and sere. What a pity it is that straight lines of trees should ever be thus planted, and specially that they should be of such unsatisfactory trees as Limes! However, here on the right hand, first passing through a small pinetum where are many noble specimens, are found the glass-houses and the kitchen gardens.

Throughout the whole of the houses there is that excellence and smartness in everything which characterises all the place. Fruit is getting over, for in

houses and on walls. Peaches, Nectarines, and Plums have been pretty well cleared. Grapes, too, have been severely cut, but there are yet myriads of bunches of the usual good late varieties to keep up a long supply. Plant-houses are full of something of everything, especially such as will contribute to the decoration of the mansion internally. Thus, Ferns, Crotons, Palms, Acahyllas, Begonias, Poinsettias, Bourdianas, Carnations, Pelargoniums—something of everything, indeed—is largely grown, and well too, for demands in this direction are great. Such useful stuff as Sunlax, Lygodium scandens, Asparagus plumosus, &c., are grown in great quantities, on strings, for giving twining sprays. That splendid winter-flowering plant, with its noble dark leafage, Begonia Gloire de Saxeau, is largely and well grown. Standard Heliotropes of Swanley Giant are made into fine plants 3 feet 6 inches high, and good clean stems; these are pushed on in pairs, and in such form used for a week at a time in the great conservatory, to give perfume. Winter-blooming Carnations are in great numbers—fine sturdy stuff, just being housed; as also are Chrysanthemums of all descriptions. Very beautiful for giving colour to vases and small plant-groups is a large batch of crimson *Clematis*, purposely sown late.

In the direction of supplying plants and cut flowers for domestic decoration, the modern gardener, especially at such places as Worth Park, has a heavy responsibility, such as his predecessors of the middle of the century never dreamt of. Violets are outside in great quantities, to be lifted and got under glass. These, like Carnations and Roses, belong to the flowers that will always be in great request, as love for them will never die. Physalis Alkekengi is grown in great quantities, indeed scores of fine fruiting-stems have already been cut to dry, and scores of more may be so shortly. These are most useful to furnish decorative colour during the winter. The kitchen gardens are well walled in, and the walls are well furnished with trees. The quarters are all fully cropped, and apparently secure, the same careful attention that is shown within the houses. Out in the pleasure grounds, much of which seems to have been fashioned but a few years, choice trees and shrubs, especially those of the early flowering form, have been largely planted. With huge groups of these are associated large perennials, bulbs, and such other plants in profusion as now usually decorate the ever-gardens.

Separating this new garden from the mansion is a huge semi-circular corridor, very broad, with a wall at the back, planted throughout inside with Camellias, of which there are scores, flat-trained and doing very well. The roof, however, is opaque. A pity it was not of glass, as it would then suit plants better. The inner side alone is of glass, but it forms all the same a delightful cold winter promenade. On the narrow border outside, and in front of this corridor, *Violas* planted in the spring were then blooming profusely. The old Blue Bell full of bloom, also the rich yellow *Bullion*, and the white *Countess* of Hopeton, were also flowering freely, as also largely in the flower-beds. *Veronica Hederifolia variegata* here makes a capital edging to border beds, and should be noted by flower gardeners. *Abutilon Thompsoni*, plunged in 6-inch pots, amidst rich crimson *Begonias*, in heat also, gave a rich effect, the plants keeping 2 inches in height, and of rich variation. The mansion, as shown in the illustration (fig. 1), is of a bold—indeed, noble character. It seems to embody the finest features of the Italian school, and whilst lofty and massive, is yet very light and graceful. It stands prominent on the higher ground of the park, with a broad belt of fine trees at the back; whilst in front runs a broad terrace-walk, from which flight of steps lead to the noble fountain-basin and parturage-garden below. Beyond is a broad expanse of park, and in the distance a fine lake, with extensive woodland beyond. The conservatory is placed right in the centre of the building, and whilst admirably suited for plant decoration, it can also be readily converted into a hall or reception room. The roof consists of a huge dome. On the north side of the mansion, and in the near pleasure-grounds, are numerous fine Crom-

Cricket and lawn-tennis grounds have been amply furnished by the gardener, who has every department in the most perfect condition. Worth Park is famous for its splendid breed of Jersey cows, and the dairy erected a few years since out in the park is worthy of the breed. It consists of two floors, one for summer below, and one for winter above. The fittings and appointments are of the most perfect obtainable, and the entire building is superbly finished; even the most modern form of cream-separator is driven by electricity. Such dairies are not for the trade; but when associated with wealth, as in this case, they are delightful to look upon and to enjoy. A. D.

Obituary.

JAMES WEBBER. On the 4th instant, at Torrington Square, James Webber, of Covent Garden, in his fifty-sixth year. By the death of this gentleman Covent Garden Market loses one of its most eminent representatives, and horticulture one of its most active supporters. In almost every public movement for the furtherance of horticulture or the promotion of the welfare of its practitioners, Mr. Webber was to the fore, taking his share in the work, as well as giving liberally to the charities connected with horticulture, and with the market and parish, with which he was so long connected. He was, we may add, one of the originators of and permanent Hon. Secretary of the Covent Garden Life Boat fund. His loss will especially be severely felt at the Gardeners' Royal Benevolent and the Gardeners' Orphan Funds. Mr. Webber also did good service in directing the attention of our fruit producers to the great necessity for the careful selection and proper packing of their consignments. For many years Mr. Webber supplied us with the greater part of our market reports, and was always ready to render us valuable information and assistance in questions connected with the market. Mr. Webber's establishment in the Centre Avenue is one of the oldest in the market, having been carried on originally by his father, and at his death by his mother, in conjunction with Mr. Taylor.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fabr. for the period named; and this combined result is expressed in Degree-degrees—a "Day-degree" signifying continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Distances from the Mean (as far as the Mean for the week or 10 days)	TEMPERATURE.					RAINFALL.	BRIGHT SUN.
	DAILY.	ACCUMULATED.					
		Day-deg.	Day-deg.	Day-deg.	Day-deg.		
0	3	11	21	146	-254	254	56 3
1	4	0	25	177	-176	176	213
2	3	11	25	142	-167 0	167 0	196
3	4	11	23	68	-111	111	190
4	4	11	22	4	-144	144	251

11	4	43	0	+32	-112	4	298

The districts in headed by number in the first column are—
 1, Scotland; 2, England; 3, Ireland; 4, N. E. of England; 5, Midland Counties; 6, E. of England, including London; 7, Principal Seaports; 8, Districts; 9, Scotland; 10, 7, England, N.W. & S. England; S.W.; 9, Ireland; N. 10, Ireland; S. 11, Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending January 7, is furnished from the Meteorological Office:—

—The *weather* continued mild and changeable very generally, considerable falls of rain having alternated with periods of clear sky.
 —The *temperature* was above the mean, the excess varying between 2° and 1°, the highest of the maxima were recorded during the middle of the week, and ranged from 37° in Ireland, N. to 51° in Scotland, N. The lowest of the minima, which were recorded on January 2, ranged from 21° in the Midland Counties, and 23° in England, N.W., N.W., and E., to 31° in Scotland, N.W., and to 57° in the Channel Islands. During the greater part of the week the minimum, even at the northern and inland stations, were much above the freezing-point.
 —The *rainfall* was more than the mean over the Kingdom as a whole, but was just equal to the normal in England, S.W. and N.E., and rather less than it in Scotland, E., Ireland, S., and the Channel Islands.
 —The *wind* was generally exceeded the mean in most districts, but was somewhat deficient in some of the west districts, as well as in Scotland, N. and the Channel Islands. The percentage of the possible duration ranged from 41 in England, E., and from 31 in Scotland, N. to 57 in Scotland, E., and the Channel Islands, to 15 in England, N.W. and E., and Scotland, N.

MARKETS.

COVENT GARDEN, JANUARY 7.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the price on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quantity of the goods, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

FRUIT.—AVERAGE WHOLESALE PRICES.

Table with columns for fruit types (Apples, Grapes, etc.), quality, and prices per unit. Includes entries like 'Apples, Blenheim's', 'Grapes, Gros Colmar', etc.

SEEDS.

LONDON: Jan. 6.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that some little inquiry has this week sprung up for Clover and grass seeds, and a few travellers' orders have already come to town.

FRUIT AND VEGETABLES.

GLASGOW: January 6.—Averages of the prices current at market during the past week.—Pears, 6d. per lb.; Apples, 1s. to 2s. per stone; Tomatoes, Gurnsey, 6d. per lb.; do, Scotch, 6d. do.; Grapes, home, 1s. to 2s. do.; do, foreign, 4d. to 6d. do.; Vegetables.—Turnips, white, 2s. to 2s. 6d. per dozen bunches; Swedes, 1s. per cwt.; Savoys, 1s. to 1s. 3d. per dozen; Cabbages, 6d. to 8d. do.; late do., 10d. to 1s. do.; Red do., 2s. 6d. to 3s. do.; Cauliflowers, English, 2s. to 2s. 9d. per dozen; do, Dublin, 2s. to 2s. 6d. do.; Parsnips, 2s. to 4s. 6d. per cwt.; Herbs, assorted, 1d. to 2d. per bunch; Leeks, 1s. 3d. to 3s. 6d. per dozen bunches; Mint, 6d. per bunch; Onions, Dutch, 3s. per bag; do, Portugal, 1s. per stone; do, Globe, 3s. to 3s. 6d. per cwt.; Parsley, 5s. to 6s. do.; Greens, 3d. to 4d. per bunch; Celery, Table, 1s. to 2s. 4d. per bundle; do, common, 9d. to 1s. 6d.; Potatoes, best, 6d. per stone; Carrots, 2s. 6d. to 4s. 6d. per cwt.; Broccoli, 2s. per dozen; Artichokes, 10s. to 12s. per cwt.; Cucumbers, 6s. to 12s. per dozen; Lettices, round, 6d. to 9d. do.; do, French, 9d. to 1s. do.; Horseradish, 2s. to 2s. 6d. per bunch; Mushrooms, 1s. to 1s. 3d. per lb.; Beetroot, 6d. to 7d. per dozen; Cress, 3d. to 4d. per basket; Brussels sprouts, 1s. 3d. to 1s. 9d. per stone; Endive, 1s. 6d. to 2s. per dozen.

LIVERPOOL: January 6.—North Hay Market: Turnips, 19s. to 20s. ton. Potatoes: Imp. ratons, 1s. 8d. to 1s. 10d. cwt.; do, Main Crop, 2s. 3d. to 2s. 9d. do.; do, Champions, 1s. 10d. to 2s. do.; do, Bruces, 1s. 10d. to 2s. 4d. per cwt.; Turnips, s. 1 to 10d. per 12 bunches; Swedes, 1s. to 1s. 4d. per cwt.; Carrots, 2s. 6d. to 3s. 9d. per cwt.; Onions, English, 4s. to 4s. 6d. per cwt.; do, foreign, 6d. to 2s. 9d. do.; Parsley, 6d. to 8d. per 12 bunches; Cauliflowers, 1s. 6d. to 2s. per dozen; Cabbages, 8d. to 1s. 4d. do.; Celery, s. 1 to 1s. 4d. roll—Birkenhead; Potatoes, 6d. to 8d. per cwt.; Grapes, English, 2s. 6d. to 3s. 6d. per lb.; do, foreign, 6d. to 8d. do.; Pines, English, 5s. to 10s. each; do, foreign, 4s. 6d. to 6s. 6d. do.; Muirberries, 1s. to 1s. 6d. per lb.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr), for the week ending January 2, and for the corresponding period in 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Table with columns: Description, 1896, 1897, Difference. Rows include Wheat, Barley, Oats.

ENQUIRY.

"He that questioneth much shall learn much."—Bacon.

CUSTARD-APPLE AND MANGO.—Will some readers of the Gardeners' Chronicle kindly inform J. S. T. if the plants mentioned above have fruited in gardens in this country?

NOTICES TO CORRESPONDENTS.

Books: Cyclanthes: and How to Grow Them. Would Mr. F. C. Edwards of 9, Sloanebecke View, Chapel-town, Leeds, kindly furnish C. B. Woodley & Co. with the address and name of the publisher of his book.

CIDER APPLES: W. Hill, Brisbane, Broadleaf Hereford, or Norman; Cherry Hereford, or Norman; Cherry Pearmain, Cunniff Hereford, Foxwhelp (old), Haadstone Hereford, or Norman; Kingston Black, Strawberry Hereford, or Norman; Wisteton Seecling. The list of cider-making varieties supplied by Mr. John Watkins, Pomona Farm, Hereford, is published in the Royal Horticultural Society's Quarterly Journal for November last.

CUSTARD-APPLE AND MANGO: A. S. T. Evergreen in India. The plants would rest during the dry season. In the hot season in this country the plants should rest during the period of least heat and light as other tropical plants have to do under cultivation.

DISTANCE OF FRUIT TREES FROM FENCES DIVIDING THE LAND OF DIFFERENT OWNERS: R. M. Year Orleans. We in this country have no law which fixes the distance at which trees of any kind may be planted from one's neighbour's boundary, although actions at law for damage, loss of light, &c., sometimes arise. In the case of overhanging branches, these may be cut off up to the dividing line, after giving the owner of the trees notice that such operation was going to be performed. The detached branches must, however, be removed by the owner of the trees.

ERRATUM.—Hardy Fruit Calendar, in last week's issue, 12th line from the bottom of the column, read, "Take the tree by the stem, and shake it in an upward direction, in order to let the soil trickle in among all the roots, and bring the latter to within 6 inches of the surface after the remaining portion of the excavated soil has been returned." &c.

LOBELIA INFLATA, &c. T. L. Wild. Seeds, my be obtained of the larger botanical gardens in the States, and so far as we can ascertain the trade does not deal in either the seeds or plants. Seeds of L. siphilitica, L. cardinalis, erinus, and others of more common employment in the garden, may be obtained of any large seed merchant in this country.

MARKET GARDENERS: H. O. If employed solely in market gardening, no licence is required to be taken out for them.

MARKET GARDENERS' COMPENSATION ON REMOVAL: J. B. A copy of the Act of Parliament to which you refer is obtainable at Messrs. Eyre & Spottiswoode, Queen's Printers, Great New Street, Peter Lane.

NAME OF FRUIT: George Dixon, Hoary Morning.

NAMES OF PLANTS: Correspondents not answer L. in this issue are requested to be so good as to consult the following number:—J. H. M. Cytisium fistulatum.

M. H. K. Epidendrum fragrans.—A. Young. Magnolia acuminata, "Cucumber tree." The leaf and note accompanying paper was being unfortunately mislaid for a long time.—L. H. P. Elaeagnus pungens.—J. D. Tussilago fragrans.

NORWEGIAN FISH MANURE: J. P. It is sold by the larger horticultural sundriesmen in London, whose names and addresses you will find in the Horticultural Directory and Year Book for 1897.

PEACH TREE NOT FRUITING: G. Hedley. Having taken the one heavy crop, a heavy was given, the result of which was a poor crop the next year, with great wood production as a result, and but few blooms, and these thrown off. Under these circumstances, there is nothing better than complete transplantation, replanting the roots very shallow, and doing nothing that will have the effect of causing an excessive growth of wood. If the cure seems to be partial, and but few bloom-buds form the first year afterwards, root-pruning or transplantation should be performed just before the leaf falls. Manure should be taken to keep the roots from going deeply; no manure should be used, and little else beyond good stiff loam and half inches bones as a rooting medium. When affording water to the border, let it be a thorough soaking when the soil on probing it shows that it really needs water.

PLANTING ON A SURREY HILLSIDE: SOIL LIGHT LOAM. G. K. Pines Finaster, P. austriaca, Holly. Thorns of all kinds, Tamarisk, Sea Buckthorn, the common Lime, Wild Crab, common Sycamore, double and single-flowered Furze, yellow and white Broom. Among fruits, the Quinces and the Medlars would do well, as well as Filberts and Cobs.

PRIMULA WITH VARIEGATED LEAVES: H. L. Variation is not common in Primula sinensis, in

so far as regards the foliage, although in the case of the flowers white-spotted exists in some varieties, and has become fixed to a certain extent. If the variegation is of a pleasing kind, and you obtain some fine forms of it in succeeding generations of seedlings, it might prove of decorative value.

REPORT UPON FILBERTS, ETC., BY MR. M. A. F. BARROW: L. Maurer. It appeared in the Journal of the Royal Horticultural Society for the year 1878, p. 100. Enquiry at the Society's office, 117, Victoria Street, London, S.W., would elicit from the secretary information as to a copy of this report being available or otherwise.

ROMAN HYACINTHS: H. A. S. The bulbs show signs of premature forcing, but there are no signs of the formation of any flower in the bulbs, so that they require another season's growth before they will flower.

SEENT MUSHROOMED MANURE: H. O. This kind of manure having lost much of its nitrogen forms only a mild manure, and answers very well as a summer mulching to such plants as do not require much feeding. It would serve as a mulch for young Peach, Plum, Apricot, and Cherry-trees that usually make too much wood if supplied with rich manure in any form; but would scarcely do for aged trees, these requiring mulches richer in nitrogen, ammonia, and potash; and it is therefore not suited for spreading over the roots of Vines growing in outside or inside borders, the Vine being a somewhat gross feeder. It is admirable for manuring land for quick-growing crops, and for early Potatoes, and is much less suited to the Brascians. It is useless as a mulch for the mulch to retain its moisture in the soil, but may be employed with good effect on flower-beds where only moderate leaf-growth is looked for, and is a little richer in manurial properties than well rotted leaf-mould.

WATERCRESS: A Notice. Nothing is easier than to grow Watercress if you have running water, or the water can be freshened by the ingress of water from the water company's pipes. Your concrete tank will need to have a layer of loamy soil, covered with gravel to keep it in position in which the plants can grow. If you can warm the water slightly, and cover the tank in frosty weather, the plants will continue to grow all the winter, but it must be remembered that under these conditions greenfly is likely to prove troublesome.

CONTINUED INCREASE IN THE CIRCULATION OF THE "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction of the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among country gentlemen, and all classes of gardeners and garden-lovers of home, that it has a specially large foreign and colonial circulation, and that it is preserved for reference in all the principal libraries.

THE
Gardeners' Chronicle.

SATURDAY, JANUARY 16, 1897.

GARDENING IN THE EIGHTEENTH CENTURY.

IN Mr. Burbidge's paper on *Reference Books on English Gardening Literature* (*Journal Royal Horticultural Society*, p. 101), he mentions the name of John Laurence, and refers to his book, *The Clergyman's Recreation* (A.D. 1714); but has omitted a much more important work entitled *A New System of Agriculture*, "being a complete body of husbandry and gardening in all the parts of them." It is a folio of 456 pages, in five books, "containing all the best and latest as well as many new improvements useful to the husbandman, &c. : wherein are interspersed many curious observations on vegetation ; on the diseases of trees, and the general annoyances to vegetables and their probable cures." by John Laurence, M.A., Rector of Bishops-Weremouth and Prebendary of the church of Sarum, London, MDCXXVI.

It commences with a dedication to H.R.II. the Princess of Wales, the frontispiece being an illustration of "A perspective view of H.R.II. the Prince * of Wales' house at Richmond"—the most severely plain and formal demesne it is possible to conceive. Two hundred and eighty pages are devoted to agriculture, in which it may be noted that he includes the cultivation of the silkworm, of which the author writes:—"It is but of late years that the silkworm hath been introduced amongst us here in England; and as yet they are not encouraged," &c.

The second book deals with timber trees, evergreens, and hardy shrubs. Book III. treats of fruit trees, and of the most desirable situations, soils, and the best methods of planting, pruning, &c. ; a chapter being devoted to the cultivation of the Vine.

Of small fruits, the Philbud (Eilbert) "is an improved kind of Hazel, and bears a fruit much admired by most, especially as an amusement over a glass of wine after a good dinner." There were three principal kinds of Strawberries cultivated—the Virginian or scarlet, the Hautboy, and the common will one. Of these he discusses the "true" and "bastard" or male kinds, and gives figures of them. "If helped with a shower of pigeon-dung in the spring, the Strawberry will produce a wonderful crop, and very large fruit." A fruit tree "little known amongst us till of late years" was the Azarole ("ratagus azarola), or Neapolitan Medlar. "It is now to be had of most nurserymen about London."

Diseases of fruit trees are then discussed,

and the author thinks that some are analogous to those of man, and names them, measles, dead palsey, gangreen (canker), consumption, yellow jaundice, &c. ; and notes that diseases, by checking growth, tend to cause much fruit, just as he had previously observed, in training fruit trees that boughs bent horizontally are more fruitful.

Book IV. deals with the kitchen garden, and therein are discussed all the vegetables then grown. The author has many pertinent remarks; thus, in collecting Cauliflower seed, "it should be saved from such flowers as are large and white, the seed of two-year-old being the best." "When you head a Cabbage, cut it slopewise, that the rain may not so easily penetrate the stalk." "Kidney Beans," he says, "is an antient food, yet it is not a century since it was accounted an extraordinary rarity in England. There are above fifty sorts; but the two most remarkable are the dwarf and a white kind, which will grow 6 feet high."

Of salads, besides all we use now, Purslane was "much admired by some," and was "generally entertained in all salads mingled with hotter herbs." There were two kinds, the green and the golden. Several kinds of Sorrel, Cherville, Bugloss, Cornsalad, Mallow, Elderflowers, Barnet, Sampier (Samphire), and Scoury-grass, were all grown as salads. In speaking of Cresses, he says:—"But the Indian Cress, *Nasturtium indicum*, is what is now most coveted in salads."

Coming to the flower-garden, the author gives "A Complete Catalogue of flowers usually known in England." This embraces ninety-nine species. Of Lilies there were only four kinds, and the author mentions how some curious persons colour the white Lily by making them absorb through their roots the lees of claret! The Tuberose he speaks of as "now become very common." The Belydere "is one of the taller sort of perennials" (*Cheopodium scoparium*), now called the Belydere Cypress. Carnations of many kinds were evidently great favourites. Our Lady's-slipper was cultivated, of which he writes:—"The flowers are sometimes of a pale yellow, and sometimes brown, tending to purple. There is also a smaller sort with a white flower, and another with purple. Pretty as they are, many of these are found in diverse places in Yorkshire and Lancashire growing wild."

The Scarlet Runner Bean was also grown as a garden flower, "whose pods are singularly good, used in pickles. However, it is now adopted for a flower. It is usually employed to adorn walls and arbours."

There are many more interesting features in the book, but enough has been said for a short notice. *George Henslow, Drayton House, Ealing.*

NEW OR NOTEWORTHY PLANTS.

PLANTS FROM ASIA MINOR.

Muscari alpina.—A charming and rare variety resembling *Muscari comosum*, and which is scarcely ever to be found in the trade.

Muscari Bourgevi.—An early-flowering species, with deep violet flowers.

Ornithogalum Haussknechtii, n. sp.—A pleasing new variety of dwarf habit, similar to *Ornithogalum oligophyllum*. The large, pure white flowers appear very early in the spring, and grow only a few inches above the ground.

Tulipa pulchella.—A dwarf Tulip, with delicate rose-violet flowers. It is the earliest of all the Tulips, and for this reason, as well as on account of

its ornamental habit, this is a specially noteworthy variety.

All the above species are indigenous to Cilicia and south-east Asia Minor. Their introduction and re-introduction are due to the German botanist, W. Siebe, of Mersina, U. D., Berlin. [By accident some of these paragraphs were assigned to the *Botanical Gazette* in our last issue.]

ABIIES ARIZONICA.

Dr. C. Hart Merriam has described (*Proc. Biol. Soc. Washington* 10, 115—118, 1896) a new *Abies* from Arizona. It is from the San Francisco Mountain region, and is remarkable for the colour and character of its bark, being one of the most conspicuous trees on the mountain between the altitudes of 8950 and 9500 ft. The substance of the technical description is as follows:—

"*Abies arizonica*.—About 15 m. high; bark a highly elastic, fine-grained cork, whitish or greyish (usually creamy white), with irregularly sinuous greyish ridges; leaves of cone-bearing branches thick, subtriangular in section, sharp-pointed at the apex, about 2 cm. long; leaves of lower branches much longer, flatter, blunt and notched at the apex, 2.5 to 3 cm. long; cones dark purple, slender, medium, or rather small; scales much broader than long strongly convex laterally, purple on both sides; bract (without awn) reaching to or past middle of the scale, its body much broader than long." *The Botanical Gazette* (Chicago, Ill.), November, 1896.

CYPRIPEDIUM × LILIAN GREENWOOD = C. BELLATULUM × C. BARBATUM WARNERI.

Cypripedium bellatulum crossed with any species that has colour, good form and size, produces a brood of seedlings that have fewer throw-aways among them than any other single species, harring always C. Fairrieanum. This form is flowering at the present time in the collection of Henry Greenwood, Esq., Haslingden (gr. Mr. Spurg), and it is one of the brightest hitherto described, ranking in quality with C. Winifred Hollington and C. Gertrude Hollington, and matching the beautiful C. × *Leyceuinum*, described in the *Gardeners' Chronicle*, 1896, pp. 522. The cross breeder in this instance has got a fair length of peduncle, the want of which is the blot in C. bellatulum; and C. barbatum Warneri has given it fine arching petals, and clearness of colour, the last, another point wanting even in C. bellatulum, with the addition of an ample spotting on the petaliferous limbs. It has been named after Mr. Greenwood's daughter, and the following is a description of the flower:—

Dorsal sepal roundly ovate, 2 inches wide by 1½ inch long, with a bright clear rose-purple flushing and prominent purplish venation, the subsidiary veins giving a character to the limb; in the basal portion is a crowd of Indian red spots, the back of the sepal being about as brilliant as the front, and only shading off into green. Inferior sepal about half the size of the dorsal, and nestling close to the pouch, concave, flushed in colour and rose-spotted; petaliferous limbs very prominent, and in this particular as to form, spotting, and flush possibly fully as good as anything yet raised; length of petal 2½ inches, width 1½ inch. The form of C. barbatum Warneri is clearly shown here, and points to its being a very valuable subject for the cross-breeder, imparting fine outlines as in C. Fairrieanum, and a clearness and whiteness so much wanted by the cross-breeder. I am satisfied now that C. × *Leyceuinum*, which is very similar in many respects to the one under notice, differing most in the petaliferous limbs, and which the writer places upon record (*Gen. Chron.* 1896, ii. p. 522), as of doubtful parentage, was C. bellatulum and C. barbatum Warneri. The petals of C. Lilian Greenwood are bright rose, with very prominent blackish-crimson spots, raised above the surface, and towards the base there are flecks of greenish white, a nice additional detail. The broadly ligulate limb are undulating, and the colours show up quite to the margin; the pouch has the form of that of C. bellatulum, but with a larger orifice, and of deep purplish rose-colour, stopping short towards the extremity, which is of a greenish shade. The folded-in portion is highly ornate, with rose-coloured spots on a whitish

* He became George II. in the year 1727.

surface, and forms a fine rest for the purely reniform staminoide, which is coloured and spotted. In growth it is stronger than the seed-parent, and the colour of its leaves is of the clouded green and indefinite yellow of its pollen-parent. *J. A.*

CYPRIPEDIUM LAWRENCEANUM HYEANUM.

Great credit is due to Norman C. Cookson, Esq., of Oakwood, Wylam-on-Tyne (gr., Mr. Wm. Murray), for his foresight in making the attempt to raise this fine "albino" of *C. Lawrenceanum*, and several others of a similar nature, true from seeds; and we have the pleasure to afford our readers the opportunity of seeing an illustration (fig. 8, p. 37) of the first to flower of the batch so obtained. In his home-raised seedling, Mr. Cookson has not only preserved the pure white of the original with no other colour than cerebral-green, but he also seems to have wrought improvements in some of the features, the whole flower, and especially the labellum, being larger than in the imported *C. L. Hyeanum*, the staminoide larger, and the petals broader. Mr. Cookson hopes to have many successions of a similar class; and in raising these seedlings true from seeds, he had done far better work than that done by so many, viz., raising indifferent hybrids.

SIR JOSEPH BANKS.*

(Continued from p. 15.)

The large collection of Australian plants, as well as the New Zealand species, were described and engraved, but not published by Banks, owing probably to the death of Solander in 1782; but they were taken up by Robert Brown, who succeeded Solander as librarian to Banks, in his *Prodrromis Florae Novae Hollandiae* (1808), together with the even more extensive collection, made by him as naturalist to Flinders' voyage, 1801-3. Brown dedicated his work to Banks, and remarked that his name would be found on nearly every page.

After leaving the Endeavour River, they passed through Torres Straits, touching New Guinea and Savu Island on their way to Batavia, to repair and re-victual. By this time sickness had made its appearance among both officers and crew, and the delay in getting their repairs effected at Batavia proved most disastrous. About ten weeks were spent in this unhealthy place, and every man was sick except a very old sail-maker, who got drunk regularly every day! Still, only eight of them actually died there; but, as may be imagined, when they left there on Christmas-day in 1770, the crew were in a weak condition "though in rather better health than they had been a fortnight before."

They had not got far on their way to the Cape of Good Hope, however, before dysentery attacked them, and scarcely a day passed without one or more deaths. Twenty-five deaths occurred before they reached the Cape, and many others were exceedingly ill, including Banks, who "endured the pain of the damned almost." Dr. Solander was taken seriously ill at the Cape, and had to keep his bed for a fortnight, so that practically no botanising was done. With regard to the Dutch ladies, Banks remarks that had he been inclined to marry, he could have suited himself there.

St. Helena was the next place of call. Very little is said about the native vegetation, but among introduced plants English Furze had already become very abundant. No time was lost now in sailing homeward, and Banks landed in good health at Deal, on June 12, 1771.

In conclusion, a few words respecting his subsequent career. In April, 1772, Captain Cook left the Thames on his second voyage round the world, and it was the intention of Banks to have accompanied him, but he was thwarted, after having made elaborate and costly preparations for the voyage. In spite of his keen disappointment, he did his utmost to promote

the objects of the voyage. The Försters, father and son, were appointed naturalists to this voyage.

Banks, accompanied by Solander, made a scientific expedition to Iceland in 1772, having, I may mention, previous to Cook's first voyage, visited and explored Newfoundland. Afterwards, when England was at war with Denmark, Banks used his powerful influence in favour of the Icelanders when they were on the verge of starvation, in consequence of our having captured Danish ships conveying provisions thither; and when Sir William Hooker visited the island in 1808, with letters of introduction from Sir Joseph Banks, he found that Banks was held in the highest veneration as the benefactor of the country. In 1778 Banks succeeded Sir John Pringle as President of the Royal Society of London, a post he held until his death in 1821. During the long tenure of this office he was constantly engaged in the furtherance of science, and although he published very little himself, he was instrumental in much that was done. He was practically the Honorary Director of Kew Gardens, for which he maintained collectors and artists in various parts of the world. He also established botanic gardens in Jamaica, St. Vincent, and Ceylon, and greatly assisted Colonel Kyd in the foundation of the Calcutta garden. Indeed, no one man has done more for botany and horticulture in this country; and it would be a graceful act to provide the thousand pounds, or thereabouts, required to print a small edition of the 700 engravings on copper, executed at his expense and still lying at the British Museum. How much he contributed to the introduction of exotic plants in our gardens may be gleaned from Aiton's *Hortus Kewensis* and other works. The characteristic Australian genus *Banksia*, of the younger Linnaeus, numbers nearly fifty species, of which twenty-one are recorded by Aiton as in cultivation in 1810. *W. Botting Hensley.*

VEGETATION OF WESTERN AUSTRALIA.

JAMES DRUMMOND'S admirable description of the vegetation of Western Australia, published in Hooker's *Journal of Botany* nearly sixty years ago, commencing in the second volume, is one of the most valuable contributions to Australian local botany extant, illustrated, as it is, by an exceedingly rich collection in the Kew herbarium, as well as in many others. The presence of such a man in the early years of the colony was a fortunate circumstance for science, because he secured for posterity specimens of many plants that have since disappeared or become extremely rare. I am reminded of Drummond's share in the botanical exploration of that now more flourishing colony, by a perusal of the late Sir Ferdinand von Mueller's article on the same subject in the *Western Australian Year-Book*, briefly noticed in *Gard. Chron.*, 1896, ii. p. 665. Drummond's is the earliest account of importance, and Mueller's is the latest. Drummond tells us, that where the town of Perth now stands was formerly a grove of *Xanthorrhoea*; and the Flame-tree, *Nyctia floribunda*, was abundant, and one of the most conspicuous objects in the vegetation. From von Mueller's account we learn that the total number of species of flowering plants and Ferns together, in extra-tropical West Australia, is 3700, whereof no fewer than 2450 have not been found elsewhere. The area in which the bulk of these singular and usually gaily-coloured plants are concentrated, is a triangle, of which Shark's Bay and the western limit of the Great Bight form the base, extending through about ten degrees of latitude. The wealth and variety of the flora may be gathered from a few figures. Of *Acacia* alone, 135 species are enumerated; and the total number of Leguminosae is about 500. Such genera as *Kennedyia*, *Daviesia*, *Chorizanthe*, *Gastrolobium*, *Jacksonia*, *Pultenaea*, and *Boissiaea*, are numerous, represented, and the showy *Climanthus Dampieri* and *Erythrina vesperiflora* are among them. The Myrtaceae number nearly 400, including fifty species of *Eucalyptus*. But from a horticultural standpoint the numerous brilliantly and variously-coloured members of the genera *Dar-*

winia, *Verticordia*, *Calycotrich*, *Melaleuca*, *Beaufortia*, and *Calethamnus*, are more prominent, though some of the *Eucalypti* have very showy flowers. Proteaceae are equally as numerous, and hardly less attractive. Epacrideae number about 150 species; herbaceous plants abound also. Thus there are 75 terrestrial Orchids, 30 species of *Drosera*, 150 *Geocalceae*, and 60 of *Stylidium*. But my object is to call attention to this flora, now much neglected in our greenhouses. *W. B. H.*

METHODS OF PROPAGATION.

(Continued from p. 764, vol. xx.)

FOLIAGED BEGONIAS.—The *Rex* varieties, of which *B. Rex* is a type, may be increased by this method, as well as *Gesneras*, *Tydeas*, *Eschynanthus*, *Cissus*, *Impatiens*, *Negella*, *Piper*, and its nearly allied *Peperomia*, and the handsome showy shrub *Toxicophloea spectabilis*. These may be readily increased by simply pegging down their mature leaves on to moist earth, in a pan or propagating-tray. The useful and elegant *Pepperworts* (*Peperomia*) are easily increased by taking their leaves and plunging them petiole downwards into moist sand kept at about 60°, and small plants so obtained are very useful as decorations for the dinner-table, forming, as they do, a pleasing contrast when associated with Ferns and Palms, and unlike these they seem to be scarcely injured by lighting-gas or dry air. Especially to be recommended in this regard is the pretty *Mignonette*-flowered *Peperomia*, *P. resciflora*.

STREPTOCARPUS.

In raising *Streptocarpus* from seed many new and desirable forms and colours will be obtained, and these may be propagated by allowing the plant to dry off somewhat, then removing the older leaves, and cutting them up as directed for the *Gloxinia*, inserting the pieces in sandy peat, and keeping them close for a few weeks, when roots will be thrown out from angles of the nerves and from the mid-rib, and soon small plants will appear, which should be left in the soil till they come to a fair strength, and then lifted and potted.

PERESKIA, ETC.

This was alluded to in my article on "Inside Grafting" as a good kind of stock on which to graft *Cactae*. *Epiphyllum* varieties may be increased by taking off the leaves, slightly withering them, and then inserting their pedicels in a mixture of sand and peat. This brings us to the *Cactus* tribe, the joints of which all strike freely in light soil kept moderately dry and warm, but these are more of the nature of ordinary cuttings.

The different Sedges, *Cyperus*, &c., now frequently used as decorative plants, are raised from seed, but if the whorl of leaves at the top be taken off, with the inflorescence attached, and this be stuck into a pot or pan of soil, and the pot stood in a saucer of water in the warm-house, the head will soon break up into many smaller ones, each of which will in time become a perfect plant. This method holds good for all the tribe—from the stately *Papyrus* (*Cyperus papyrus*) of the Nile, to the Umbrella Sedge of Madagascar (*C. alternifolius*), and the still smaller varieties, *Japonica* and *viridis*, or *laxus*, all of which are handy decorative subjects. *Experientiae.*

(To be continued.)

NOVELTIES OF 1896.

(Continued from p. 17.)

STONE AND GREENHOUSE PLANTS.—Messrs. F. Sander & Co., St. Albans, at the meeting of the Royal Horticultural Society, Nov. 24, received a First-class Certificate for *Draecena Broomfieldi*, a South Sea Islands plant, and which was generally considered one of the finest introductions of late years. At the great show at Dresden also, Messrs. Sander bore off the Gold Medal with *Calamus Carola*, and during the year they have produced many good things, among which may be enumerated as new or receiving the highest recognition throughout the year: *Asplonia altivirens*,

* *Journal of the Right Hon. Sir Joseph Banks*, during Captain Cook's First Voyage in H.M.S. *Endeavour*, in 1768-71, to Tierra del Fuego, Otaheite, New Zealand, Australia, &c. Edited by Sir Joseph D. Hooker.

Anthurium Andreanum Kelley's var.; *Sarracenia Sanderiana* and *S. Sanderi*, *Asparagus tenuissimus* var. *Albanense*, *Calamus Alberti*, *Eriocaulon Fascinator*; some fine sets of foliage *Begonias*, *Sonerilas*, several *Streptocarpus*, two new *Dipladenias*, and various other good and interesting plants.

Messrs. Linden, l' Horticulture Internationale, Parc Leopold, Brussels, distributed in 1896 many of their fine new plants which had been previously exhibited. Of those specially worthy of mention are *Anthurium S. herzerianum*, "Géant Sanglant," one of the largest and most brilliant in colour; *Adiantum lineatum* and *A. Clavatum*, two charming variegated Ferns; *Zamia Noveboracensis*, a very stately species; three

since *A. Farleyense*, which it somewhat resembles, but has the dense clustered pinnae of *A. Pacoti*; the *Asplenium Herbstii* of Mr. H. B. May has remarkably fringed fronds, and the *Pteris Childsii*, and of Mr. F. Childs, *Pteris Drinkwateri* of Messrs. Stroud & Co., should both make their way in the market.

For the rest, Messrs. Laing & Son still continue to get acceptable novelties in *Begonias*, of which their fine fimbriated section was well shown in E. Duchess of Fife at the Temple show; also *Gloxinia Caladium*, *Streptocarpus*, and the other things of which they make specialities; and Messrs. Cannell & Sons, Mr. T. S. Ware, and others have shown good new *Begonias* and other florists' flowers.

nials, Messrs. Kelway & Son, and Messrs. Burrell & Co. show many advances; and among *Dahlias*, Messrs. Keynes, Williams & Co., Messrs. J. Chas. & Sons, Chas. Turner, T. W. Gillestone and others have shown good work; and the *Chrysanthemums*, which form so important a class of florists' flowers, and which in their season could not be replaced by any combination, have been well recruited, as set forth in Mr. C. E. Pearson's able paper in the *Gardeners' Chronicle*, November 28, 1896.

This hurried review discloses much careful plodding work, and indicates plainly the unflagging interest both of the providers and purchasers of garden plants.

Among the most remarkable or new plants illustrated in the *Gardeners' Chronicle* in 1896, are:—

- Acidanthera bicolor*, October 3, p. 293.
- Antirrhinum*, Cannell's new dwarf, August 22 p. 221.
- Begonia* (Laing's fimbriated), Duchess of Fife, June 6, p. 711.
- Camoensia maxima*, November 14, p. 596.
- Ceanothus thyrsiflorus*, September 26, p. 247.

FIG. 8.—*TYRRIEDRUM LAWRENCEANUM* HYBANUM, FROM MR. COOKSON. (SEE P. 36.)

varieties of *Begonia Faureana*, as well worthy of cultivation for their elegant habit as for their beautifully-tinted foliage; a splendid set of new hybrid *Bertolomias*, with diverse ornamented leaves; *Caladium adamantinum*, and *C. liliifolium*, two new types; several new and handsome *Palms*; the pretty *Dichorizandra angustifolia*, *Dieffenbachia melencris*, *Heliconia spectabilis*, *Lobelia surragina*, *Tradescantia dilecta*, *T. superba*, *Philodendron Devansyanum*, *P. robustum*, and *Davallia Truffautiana* (First-class Certificate, R.H.S.), a most lovely Fern, with finely-divided fronds, which on producing spores may probably prove to be no *Davallia*, but none the less beautiful.

Of other plants which received awards in 1896, *Adiantum Bessonianum*, which secured a First-class Certificate July 11, is the finest *Adiantum* introduced

Messrs. Barr & Son have been constant in making a display of herbaceous perennials and bulbs at the Royal Horticultural Society's and other shows, and have secured awards for *Narcissus*, species of *Tulip*, *Iris*, &c., as well as showing many fine old plants which are not so much used in the gardens as they should be.

Among Carnations, Mr. Martin Smith, of Hayes Common, takes the lead with a large number of good new kinds; and Mr. Douglas, Mr. C. Turner, and others, contribute well.

Of tree or perpetual-blooming kinds, Messrs. B. S. Williams & Son, of Upper Holloway, who make a speciality of this class, are sending out *C. Queen of the Yellows*, and *C. John Peter Rogers*, a fiery scarlet, both of excellent merit.

In *Gladiolus* and other showy bulbs and peren-

INDIA.

ODDEYPORE GARDENS.

It is not very long since we commented upon the damage done in one of our Colonial Botanic Gardens by incursions of elephants, from which our native horticulturists are happily free. In the annual report on the gardens of His Highness Maharani Fatih Singhji of Odeypore, we read about some equally unwelcome intruders with which the superintendent, Mr. Thomas H. Storey, was called upon to cope. He writes that the "wild pigs gave me a lot of trouble. The larger boars are fierce and determined, not in any way afraid of a man with a spear or stick. One poor fellow was so maulled by a boar that he had to be taken to the hospital, where one of his legs had to be amputated; he is slowly recovering. The pigs are very fond of the Lotus roots; most of the garden-tanks were dry all the hot weather, and the pigs took advantage of this by simply rooting and devouring the roots. The ground in the morning looked as if so many ploughs were at work during the night. The variety of Lotus they are so fond of *Nelumbium speciosum*.

"Panthers sometimes pay us a visit, one pretty brute took up his abode in the hollow of an old Red Tamarind tree in the nursery.

"Black feral monkey are frequent visitors, and are very destructive in a garden. A party of them visited the grafted Mangrove and helped themselves to the Mangos; they were only, however, able to take one fruit each, and bolted on to the boundary wall, making faces in defiance at the watchman." Flying foxes, the buncher or toddy cat, squirrels, and parrots are also great misdoers, while field rats and mice have to be reckoned with.

Considering all these drawbacks, it is all the more satisfactory to learn that the gardeners are in flourishing condition, and the report in every all that could be wished.

SEEDS FOR INDIA.

In some quarters it has been stated that there is no objection in sending seed to India, as the real danger consists in the absence of rain to cause it to grow. In north-western India, according to the *Pioneer Mail*, the seed is wanted as well as the rain. The seed is required for sowing in the close vicinity of the wells, the little patches thus irrigated becoming productive gardens. The result of recent Government action, therefore, will be to ensure the existence of thousands of flourishing green patches, which might have remained sterile, because the seed was not to be had.

NOTES ON CHRYSANTHEMUMS.

Each year there is introduced a host of new varieties, and by one grower or another most of these are described as "improvements." To keep abreast of the times, in regard to our collections, a yearly criticism of the list of varieties it contains is a necessity. It is difficult for the inexperienced to choose the good from the bad. A considerable amount of space, time, and attention is required to test even a portion of those sent out. The vendors' description of varieties is sometimes misleading, but confidence may be placed in the leading firms to recommend worthy varieties only.

The largest increase is in the Japanese section; seed is more readily obtained from these, and the proportion of varieties of merit among the seedlings is greater than in the other sections. White and yellow-flowered varieties predominate. In the former group, Avalanche, Stanstead White, Mlle. Marie Hoste, which were thought so highly of a few years since, are now superseded by Madame Carnot, Western King, Madame Ad. Molin, Madame Ad. Chatin, Mutual Friend, Elsie Treichman, Niveum, Lady Northcote, and Lady Byron.

Amongst yellow-flowered varieties there are now some magnificent flowers. W. H. Lincoln, Sunflower, Thunberg, Boule d'Or, Golden Wedding, Mrs. Spaulding, Mrs. J. S. Fogg, and Wilfred Marshall, are superseded by Modestam, G. J. Warner, Australian Gold, Admiral Avellan, Golden Gate, M. Pankowke, H. L. Sunderbruck, Ocean, Edith Tabor, and C. W. Richardson. All these are worthy to be added to the most select collection.

Bronze-coloured Chrysanthemums are deservedly popular. For decoration or the exhibition-table this colour is convenient. The best and newest sorts in this section are Robert Owen, which has stood the test of time, and still occupies a high position; Mrs. John Shrimpton, Mrs. Herman Kloss, M. Chevon de Leché, and Mons. Ch. Molin.

What I term pink or bluish-coloured varieties, and which represent a pleasing section, are Rose Wynne, Mrs. W. H. Lees, Mrs. H. Weeks, Graphie, International, Miss Rita Schroeter, Pride of Exmouth, and Madame Hoste. Bright red and purple-coloured varieties are much more abundant now than was the case a few years since, although there is still room for improvement in this type. Deuil de Jules Ferry, Dorothy Seward, Eva Knowles, Miss D. Shea, Mons. Joany Molin, Reine d'Angleterre, Australe, Pride of Madford, Mrs. Home Long, Nyanza, and President Borel are some of the best. *E. Molignon*.

LATE-FLOWERING CHRYSANTHEMUMS.

The smaller-flowered Japanese Chrysanthemums, many of which are so useful for decorative purposes, are consigned to the rubbish-heap before their value as such is tested, owing to the demand for varieties producing large exhibition blooms. From this cause it is probable we lose many that would be very desirable as late bloomers. A variety named Princess Victoria, of which I had a few cuttings given me last year, proves to be a very valuable one for producing flowers naturally towards the end of December and later. The colour, before fully expanded, is white,

with a lemon centre, passing to pure white when fully developed. Plants once stopped and potted on into 7 and 8 inch pots, carry eight and ten good flowers, and have a sturdy growth, with good stout flower-stems that carry the bloom perfectly erect. Niveum is better known, and is a useful variety for late work; plants stopped once produce good flowers at the end of December, but the petals are not so stout and lasting as the preceding variety. W. H. Lincoln appears still to be the best yellow late-flowering kind, a batch grown in 8-inch pots and once stopped, is just now in full bloom. This is a well-known variety, of dwarf and erect habit. A good late dark red variety is greatly needed. *C. Irvia, Dropmore, Malsheul*.

[Several of the Chrysanthemum nurserymen pay as much attention to promising "decorative" seedling varieties as to mere exhibition kinds. ED.]

CULTURAL MEMORANDA.

EPIPHYLLUMS.

It is disappointing to see so few Epiphyllums in gardens at the present day. They constitute a genus of very handsome, branched, slender, stove sub-shrubs, all natives of Brazil. They are among the most highly-coloured and beautiful of winter-flowering plants, and are extremely useful in decorations at the present season in plant-houses and apartments. Being of a dense trailing or pendent habit, I have found them effective when grafted on a small tree-like stock of *Pereskia aculeata* or *P. Bleo*. The species are few, although the varieties are numerous; they are nearly all richly-coloured and attractive. Propagation of the plant is simple, and consists of taking short cuttings in the spring from the branches, inserting them singly in thumb-pots, plunging these in a brisk heat in the propagating frame. This mode of propagation is not so much in practice as that of grafting. For general decorating work, it is always advisable to have a few plants of the former for use in baskets or in other positions where they are intended to hang down. They succeed best in a compost consisting of good sandy loam, with the addition of a little leaf-soil and mortar-rubbish; good drainage is also very necessary, and small pots proportionate to the size of the leaf should be used. After grafting the plants should be grown on in heat, until the autumn, and then afforded less water, and allowed a short rest. Start them again in the month of February, and grow them in a light position, allowing them plenty of air towards the latter end of the summer to ripen the young growths. By this time the plants will have formed new heads, and a few of them may be taken into warmer quarters to flower, if being always prudent to move a few at a time, so as to prolong the flowering season. A temperature of 60° should be afforded in bringing them into flower at the ends of the flattened branches. When in bloom, remove the plants to a cooler position, and follow the same routine. *J. H. C. S., Cheshire.*

THE PROPAGATION OF GRAPE-VINES FROM "EYES."

If the gardener wishes to fruit his pot Vines in their second year, a beginning must be made early in the new year. Assuming that stout, firm shoots were laid aside in damp soil at the autumnal pruning of the Hamburgh, Foster's Seedling, Sweetwater, Mascadie, or other desirable quick-ripening grapes, these may be cut into lengths of one bud each, making the cut end which will enter the earth somewhat slanting. Having made the required number of eyes, prepare some sandy loam in which to strike them. Some gardeners use 9-inch puns, others small pots, or pieces of turf with a hole scooped out in the middle. After inserting the eyes, stand them in a forcing-house for three weeks, and after that time plunge the pots, &c., in bottom-heat of 80° in a hothed with a top heat of 70°. The operator must take care to place the eyes in the soil with the buds just level with the surface, and to make the soil very firm round about the eye, and if a pinch of sand

be placed about it, there will be less danger of loss from excess of moisture in the soil. Provided the soil was moderately damp when used, no water will be needed for some few days; and I have found excellent results from keeping green moss on the surface of the soil and placing it there till growth has begun in the Vine-eye. With development of growth and formation of roots, the amount of moisture in the soil must be increased, and sufficient air afforded as will prevent damping. When the shoots have reached a height of 4 inches, the pots should be partially raised out of the plunging material, and when the soil has got permeated with roots a re-potting should take place. On this occasion the compost may consist of rich fibrous loam, finely broken linseed-rubble and charcoal, and a small quantity of bone-meal, although this last should be sparingly used till the Vines come into their last pots. Before proceeding to repot, the soil must be made as warm as that of the hothed, otherwise a check may be given which Vines rarely get over, indeed the plants should from first to last be kept steadily growing with abundance of water, and afforded daily syringings. They should be in all respects treated similarly to Vines which are forced into early maturity.

It need only be said here that the Vine shoots should be trained to strings or wires running either vertically or horizontally in a well-lighted forcing-house, and when they have reached a length of 6 to 7 feet the point may be pinched-out at about the third bud beyond the point to which the cane will be pruned back in the autumn. All laterals must be stopped at the first joint, and then allowed to make another joint and be pinched again throughout the season. If the Vines have made good progress the bark will be of a rich brown colour by the end of the month of July, and in August or early in September they should be removed to a south wall, or even against a hedge facing the same point, where they may remain till winter sets in. *H. Markham, Mereworth.*

FORESTRY.

TYPES OF BRITISH WOODLAND.

Regarding Beech woods from an ornamental point of view, few have a more characteristic appearance, or vary so much with the season as these. A landscape (if we can call it such) which contains nothing but tall grey stems, and a ground covering of reddish-brown leaves, may not be altogether attractive to some tastes. Mrs. Poyser reckoned that the mitre had to be bred in the rotten chest to like it; and perhaps it requires a native of Bucks to appreciate Beech woods at all times, but speaking for ourselves, we should say that from mid-summer to September was the most interesting period during the whole year. The dense foliage shuts out every ray of sunlight, and all those alternating lights and shades which constitute the chief charm of ordinary woodland scenery in summer are absent. The dingy monotonous green canopy, which gets still dingier as autumn approaches, causes an almost twilight shade, beneath which neither bird nor insect life shows itself. But for a fortnight or three weeks in spring, and for a longer period in autumn, Beech woodland scenery defies successful imitation by the most skillful artist, the nearest approach to a Beech-wood in May we have ever seen being in a Drury Lane pantomime! A more delicate green than that of a newly unfolded Beech leaf could scarcely be imagined, and the way in which certain branches suddenly burst into leaf in advance of the majority, is almost unique in its effect on a sunny spring day. In autumn, again, the tints of the Beech are deeper and richer than any other indigenous tree, and have a particularly fine effect on a bright October day. Apart from scenery, certain features of a Beech-wood in autumn rouse feelings which serve to remind us that man is only a (more or less, chiefly less) fine animal after all. The rustle of a thick carpet of dry leaves, the constant showers of these which every breath of wind

brings down, and the rushing noise caused by innumerable wood-pigeons, which one's approach disturbs, inspire us with a wild sense of freedom, which no other kind of wood seems to do. Perhaps a few dormant traits of a prehistoric existence may thus be excited into consciousness by the mere force of instinctive association, just as our domestic animals still retain certain habits which are only occasionally brought out under favourable circumstances.

But to return to our subject, the winter aspect of Beech-woods requires a few words. This is decidedly of an architectural character, in all probability the original type of our colonnades and vaulted roofs of modern architecture. To see this feature of a Beech-wood to perfection, it requires, like "fair Melrose," to

THE ROSE GARDEN AND FERNERY AT WALTON LEA.

We afford our readers in the present issue two views in the gardens of John Crosfield, Esq., Walton Lea, near Warrington, namely, the Fernery and the Rose Garden. The last-named (fig. 10) is laid out in a series of circular beds, bounded on one of its sides with a wide border, and is situated, as it is very necessary a Rose-garden should be, in an area fully exposed to sunshine, and yet sheltered by distant trees and shrubberies from destructive winds. The shapes of the beds in their freedom from angles make them admirably adapted for the purpose of growing Roses; and one could only desire to hide the soil somewhat by some kind of

feature in a garden that is more than usually full of interesting things. The fernery measures 120 feet in length by 40 feet in width, and it has been formed at different times, as suitable materials could be collected for forming the mounds. Once made and planted, it is kept in good order at a minimum expenditure of labour and time.

THE HERBACEOUS BORDER.

PLANTING HERBACEOUS PEONIES.

There are very few subjects indeed that can surpass as garden plants a collection of the best varieties of these Peonies, bold and vigorous in

FIG. 9.—THE FERNERY AT WALTON LEA, WARRINGTON.

to be seen by moonlight, for only then can the eye rest with ease upon the network of branches overhead is dimly reproduced in shadow on the ground below. The outermost twigs, which by daylight obscure the outline of the large branches are then less noticeable, and we only note what may be termed the skeletons of individual trees, which to the observer at least are their most interesting features. The study of a thick leafless wood by moonlight also enables one to see the effect of light upon the growth of the trees pretty accurately. The relative size of crown and stem can be clearly seen, and the amount of space between adjoining crowns affords a fairly reliable guide regarding the light requirements of the particular species. *A. C. Forbes.*
(To be continued.)

colging plants, as Fairy Roses, R. Paquerette, R. polyantha, Campanula pulla; and, in the case of the larger beds, with *C. carpatia*, tuberous root-d Begonias, or the homely Mignonette.

The fourteen separate beds contain, as Mr. Kipp's, the gardener, tells us, the following varieties:—Alfred Colomb, Baroness Rothschild, Charles Lefebvre, Francois Michon, John Hopper, La France, Mille, Suzanne Rodocanachi, Louis Van Bontte, Margant Dickson, Marie Baumann, Merveille de Lyon, Ulrich Brunner, Grace Darling Viscountess Folkestone—some, therefore, of our best old and new lines. As will be observed, the entire display is obtained from dwarfs.

Our other illustration (see fig. 9) is a representation of a part of the outdoor fernery, a pleasing

their habit of growth, possessing ample foliage, and massive gorgeous flowers. There are now in cultivation very many excellent varieties, and particularly among the white and creamy-white flowering ones. Some of the flowers are pure white, others again are white with occasional splashes of colour; then, very beautiful are the shades of pink; and apart from these more delicate shades are others of more intense colour. Yet one rarely sees a good collection of them. Sometimes the old double crimson form of *P. officinalis* is seen in big bold clumps the result of many years' growth, and very fine indeed is the effect of the blooms, sometimes as in my as a score or more on a plant. They are sometimes planted in the shrubbery, not unfortunately already overcrowded with shrubs, and the soil quite impoverished. In such a

placed most plants flat, and of all places the thickly cropped shrubbery is the worst in which to plant these Peonies. Deep rooting, and of great natural vigour, they cannot attain anything like perfection unless in deeply worked and very rich soils. I have known their roots descend more than 3 feet into the earth, and when they do this the plants are not likely to suffer in times of drought. In all cases the soil should be deeply trenched, and manure may be added with a liberal hand, but always selecting a position free from the influence of tree-roots. The early autumn is the best time to plant, and preferably the end of August, while their foliage is retained. This is the most rational season to plant, if we study the time and way in which the new roots are produced. Where it is followed large plants seldom feel much of the shift, and flower fairly well in the following year. Not so those that are replanted at any haphazard period, particularly when growth has recommenced, which is of all seasons the worst for moving the plants. If the planting cannot be done at the end of August or throughout the autumn, selection should be made to get it done before the end of the year. Some nurserymen, who make a speciality of Peony culture, lift a certain number of plants in August or September, with which to fulfil late orders, and lay them in readiness. This produces a sort of time-check on the fresh roots that would have been made had the plants remained undisturbed, and plants thus treated invariably give satisfaction when replanted. In my own case, I have found it of service to lay the divided plants in coal-ashes in preference to soil. They keep the plants and crowns quite plump, and they have not the tendency to root afresh so quickly as in the moist soil. Once planted properly, Peonies may remain a dozen years without further disturbance, but require a heavy mulch of manure each autumn. J.

THE WEEK'S WORK.

THE FLOWER GARDEN.

By CHARLES HERRIS, Gardener, Droppore, Malabar.

Planting Deciduous Trees and Shrubs.—Continuing my remarks on this subject, I will next take Magnolias of this section, which are mostly early-blooming shrubs, that do most successfully when planted in somewhat sheltered positions. *Magnolia conspicua* is one of the best and earliest flowering of these. *M. purpurea* and *M. p. Leonie* varieties which are rather later in flowering, but which very desirable; while *M. stellata* or *Halliana*, a smaller-flowered variety, of dwarfier growth than either; and *M. glauca Thompsoniana*, a summer-flowering fragrant variety. *M. tripetala* is a strong grower, with handsome flowers and leafage, worthy of mention. Among Prunuses, *P. Pissardi* is a very effective variety, which, besides having the advantage of flowering early, has foliage of a dark red, contrasting well with that of other kinds of shrubs. Of other species mention may be made of *Calycanthus floribus*, *C. precox*, *Rhus*, *V. rotundus*, *Cereus silvanstrum*, *Viburnum Opulus*, and *V. plicatum*, *Sambucus nigra* aurea, the *Broom*, including *Cytisus filipes*, the Spanish Broom, which blooms so persistently throughout the summer, *Lyrus floribunda*, *P. Mahoe*, *P. M. bacata* and others, *Ribes sanguinea*, *Dier-villensis*, and Japanese *Acer*. The hardy Ghent and Pontic Azaleas should be planted in quantity where the soil is or can be made suitable for their successful culture. It need not necessarily be peat, as the plants grow freely in any moderately light sandy kind of soil that is free from lime in any form, and which in preparing it has received a good dressing of rotten leaf-mould.

Summer Bedding Plants wintering in cold frames, viz., *Calceolarias*, *Gazanias*, *Violas*, *Antirrhinums*, *Begonias*, and others, should be afforded abundance of air in mild weather, otherwise they will be much less of foliage. Great attention will be required in removing decaying leaves, stirring the surface of the soil, and in affording water.

Herbaceous Borders.—There is an advantage in leaving the growths of early-flowering *Chrysanthemums*, and some other plants, as a protection to the stools, but this not being permissible always, a mulching of partly-rotted tree-leaves, spent Mushroom-bed materials, or fine coal-ashes may be afforded instead; and among the more susceptible subjects to be so treated are *Fuchsias*, *Montebretia*, *Zauschneria californica*, *Agapanthus umbellatus*, *Aloysia citrifolia*, *Golden Sage*, and *Salvia rugens*. Of border *Chrysanthemums* it is advisable to lift a clump or two of

each variety, place in boxes, and introduce to an intermediate or cool-house to furnish cuttings. No frosts of sufficient severity have as yet occurred to injure any of these subjects, but as severe frosts often sets in suddenly it is well to be prepared. Choice or scarce varieties of *Michaelmas Daisies* will be increased now by potting up young suckers from the old plants, and keeping them in cold frames, or plunged in ashes under some shelter for a month or two until fairly rooted. The flowers of these plants are of so much value in the garden and dwelling that no gardener would be without at least a small collection of them. The old-fashioned varieties of pillar roses are in keeping with herbaceous borders, and when trained to stout stakes they constitute a desirable feature in the background of such borders. The planting of *Roses* should now be finished; bulbs of Spanish and English *Iris* which were planted in the autumn or early winter, but where they are not yet planted, no time should be lost in getting the operation finished. During mild, damp weather, slugs are sure to be troublesome, eating off the young shoots of *Delphiniums* and other subjects, but a dusting of the plants and the soil around with soot, or very fine coal-ashes, will help to keep these creatures away from the plants. If new borders are going to be formed, the ground must now be trenched and got in readiness. If the staple is of a heavy nature, leaf-mould or charred garden refuse may be incorporated with it; taking the opposite course with soils that are light or sandy, trenching in solid farmyard-manure, clayey loam, &c. Existing borders may now be dressed with rotten manure, which may be lightly forked in a few weeks later.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Easton Castle, Ledbury.

The Peach.—If some ripe fruits are required in May and June, some examples of *Queens* should now be started, choosing those which are showing signs of throwing up, which can be known by the central tuft of leaves showing a tendency to open out. Ascertain the state of the soil, which should be moderately moist, and if a plant is found to be dry at the root, afford it sufficient warm water to moisten the ball throughout. These selected plants should be plunged in a bottom-heat of 50° to 85°, the house having a top heat of 65° to 70°, and 10° more with sun heat. Syringe the bed between the plants, and the walls and floors, twice or three daily, having regard to the weather. Afford air in small amount on sunny days, doing this very carefully at the present season. As the plants show for bloom, the temperature may be gradually raised, and when the flowers are expanded, a dryer and more buoyant atmosphere should be maintained, so that every flower will set. Afford liberal supplies of tepid liquid manure when the fruits commence to grow visibly in size.

Successions.—These plants should not be excited before the end of next month, but do not allow them on the other hand to get too dry at the roots, or some will prematurely show for fruit. In order to facilitate operations next month, a good heap of potting compost may be prepared, and the following will be found an excellent mixture.—Take the required quantity of good friable loam that was obtained from an old pasture which has been stacked for three or four months, cut or pull the stalks into good sized pieces—shaking out much of the fine soil, spread these out on the floor of a shed, and sprinkle over the soil a good proportion of half-inch bones, and a smaller one of fresh soot; mix thoroughly, and make into a heap in a dry shed till required for use, when it should be placed somewhere to get warmed to the same temperature as the bed in which are the plants to be potted. Have pots and crocks all washed in readiness.

Cherries and Plums.—Where these fruits are grown under glass, and they are required early in the season, a start may now be made with pot-trees; and as these do not like hard forcing, a temperature of from 40° to 45° at night, with a rise to 50° by day, will suffice at the commencement, and for some two or three weeks. Be sure that the soil in the pots is sufficiently moist, cherries especially being impatient of a soil that is either too dry or too wet. The trees should be lightly sprinkled at closing time, if the day has been sunny, and just before the buds burst has been sunny, and just before the buds burst afford the house a gentle fumigation in order to destroy any lurking aphid, as fumigation cannot take place till the blossoms are set. Afford air abundantly in favourable weather, close early in the afternoon in fine, and earlier in cloudy cold weather, but do not

allow the temperature to run up beyond 80°, or the fruit will drop.

Tomatoes.—Fruiting plants will now be getting somewhat exhausted in carrying fruit in any quantity. They should be afforded a liberal measure of water when root-moisture is required, and a second crop of fruit is looked for, the foliage should be removed, and the stronger shoots tied-in thinly as growth recommences. The flowers should be artificially fertilised in order to ensure a better set than would otherwise be obtained. Pot-off seedlings and cuttings, and place them near the glass; and sow a few seeds at intervals for succession.

Cucumbers.—Winter Cucumbers will now have passed the most critical time; let a moist growing temperature of 60° to 65° at night be maintained, admit a small quantity of air in mild weather, and endeavour to encourage growth, a light covering of stable-litter placed over the bed will be found beneficial, taking care however that the rank anatomical fumes have passed away from it before use. When growth becomes more free, the old foliage should be gradually removed, young growths stopped and tied in thinly, the fruits well thinned in number in order that a regular good supply may be obtained from the plants till young plants come into bearing. A few seeds may be sown and raised with the *Melous* to fill up probable vacancies among the winter fruiters.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Dendrobiums.—Our plants of *D. Wardianum*, *D. crassinode*, *D. Linavium* (moniliforme), and the distinct hybrids *D. micans*, *D. Douinii*, *D. Aleippe*, *D. Clix*, *D. Aspasia*, and *D. Wardiano-japonicum*, are now showing their flower-buds. In consequence of the present mild weather and the deficiency of sunlight many of these plants have commenced to make new growths from the base of the flowering bulbs. The grower should not be tempted by this to give them very much water at the root or a high temperature, or the young growths will make increased progress, and the flower-buds probably turn yellow and fall. Place such plants in a Cattleya or intermediate-house, upon the lightest side of the house, and keep the compost moderately dry until the buds commence to develop, when each plant may be given a thorough watering, and placed in the lightest available position in the East Indian-house. If the pseudo-bulbs show the slightest tendency towards shrivelling whilst the plant is in bloom, a little water should be sparingly given. Such plants as *D. noble*, *D. Ainsworthii*, *D. dulce* (East Indian), *D. Juno*, *D. splendidissimum*, *D. Leechianum*, *D. Schiedeanum*, *D. Cassiope*, *D. Virginica*, and the *D. melanodictum* and *chrysanthoides* crosses are not so difficult of management; they may, therefore, be removed from the Cattleya-house into greater warmth so soon as the flower-buds are well advanced, and be carefully watered until the blooms are past. *D. crepidatum*, *D. crotaceum*, *D. pruinatum*, *D. superbum* (macrophyllum), and its varieties *eusomum*, *gigantum*, and *littatum*, should be suspended close to the roof-glass in the East Indian-house, and be kept rather dry at the root until the flower-buds appear. Plants of the evergreen section, as *D. densiflorum*, *D. thysiflorum*, *D. Griffithianum*, *D. stansissimum*, *D. Chrysanthoides*, *Schroderae*, and *D. Farmeri*, now resting, should at present be kept in the coolest part of the Cattleya-house, and if the growths were thoroughly ripened they will need little moisture. If, however, they are neglected, and allowed to shrivel, the leaves prematurely turn yellow, and in a short time fall off. The tall-growing species, as *D. finlaysonianum*, *D. moschatum*, *D. Paxtonii*, *D. dioxanthum*, *D. clavatum*, and *D. calceolus*, if placed in a house where the night temperature is about 50° to 55°, and be kept rather dry at the root for the next two or three months, will produce larger spikes than in any other summer. The beautiful *D. Dalhousiana* enjoys the temperature of the East Indian-house at all seasons, and must on no account be allowed to shrivel for want of water; for though conducive to large spikes of bloom, the after-growth is often deficient in size and strength. The comparatively new *D. Phalenopsis* should be placed in the cooler part of the same house, and no water will be necessary unless shrivelling is feared. The pretty Australian *D. acuminatum* is now flowering in the cool-house. It should be cultivated in a teak-wood basket or shallow pan, and given very little material to root into. During growth it requires a temperature slightly higher than that which the *Otoglossum*-house affords, but it must be very carefully watered, as the young growths are liable to

damp off. When these growths are completed, place the plant close to the roof glass in the cool-house, and keep it perfectly dry at the root until the flower-buds are well advanced. After flowering and until growth recommences, dryness at the root is advisable. The same kind of treatment is necessary for *D. Kingiana* and its varieties.

PLANTS UNDER GLASS.

B. G. H. MAYCOCK, Gardener, Laton Wood, Luton.

The Conservatory.—To maintain a good supply of flowers in this house, cleanliness must be enforced, and a suitable temperature maintained. The plants will do best in a house until they are well cleared by sponging or fumigation. Cyclamens require very careful watching to prevent injury from thrips. The thrips secrete themselves near the crown of the bulb, and attack the flower-stems as they appear. Greenfly is the greatest enemy of Cinerarias, and to keep the plants clean, incessant care is needed. Continue to afford support to the shoots of *Borvardias* in flower, and keep watch against scale. The atmosphere of the house should be kept buoyant, avoid extreme temperatures, and give air on all favourable occasions.

Greenhouse Climbers.—*Impatiens* are best trained over corridors, where their pendant flowers may be seen to advantage. They do best planted out in a prepared bed of three parts peat to one of loam, with plenty of sharp sand and charcoal, and over efficient drainage. Little pruning is needed until the plants have filled the available space. Being half-hardy they should be kept as cool now as possible. *Clematis indivisa lobata* is better adapted to trail along wires or up columns. It should be planted out or potted forthwith in good rich loam, and sufficient charcoal to keep it open. Thin out the growths, and keep those remaining free from brown-scale. *Plumbago capensis* may be planted against back walls or trained on balloons. Give them a mixture of three parts loam to one of peat, and a liberal quantity of sand. They may be pruned hard back each year after flowering. *Bignonia venusta* is worthy a place in every collection, and when once established it is one of the loveliest of greenhouse climbers, and very free-flowering. It is best seen to advantage if trained up the roof of the house, and some of the growths allowed to hang loosely. It may be planted on the south side of the conservatory, as the plant is fond of sunlight, where it will afford a slight shade for the plants underneath in summer. The plant should be given a good root run—say, about 3 feet by 2 feet space. Plant in a mixture of one half rough loam, one part leaf-mould, and one of peat, this will continue good for two or three years if the loam used is not cut too small. During the growing season lightly syringe in the afternoon, and prevent growths from becoming matted together. Train the leavers 3 inches apart, and let the lateral growths be suspended at intervals. After flowering, and when the limit has been reached, a thinning-out of the growths should be done, and this is all the pruning required. *Trachelospermum jasminoides*, a plant of somewhat easy culture, may be trained along the rafters, or balloon shape, as required. It thrives well in a mixture of half loam and half peat, with plenty of sand; prune-back, and keep well syringed during the growing season. The flowers are very useful for the making of bouquets. The variegated form makes a strong plant, suitable for large vases, if trained for that purpose. *Asparagus plumosus*, if planted out in the cool house or on the back wall of ainery or Peach-house, will afford plenty of cutting material, and does not require the amount of heat often given.

General Work.—Gradually lessen the water given to plants of *Euphorbia pulcherrima* (Poinsettias) and *E. Jacquiniflora*, that have flowered, and place them in a cooler house, in a position near the glass. In the cool house the specimen plants of *Azalea* or *Heaths* should be turned round once weekly to expose all sides to the light. Never allow the plants to become very dry, and thoroughly saturate the roots at each watering. Large plants of *Brygnansia* (*Datura*) *Knightii* should now be pruned hard back, and afterwards washed with some good insecticide, as they are subject to white scale.

THE KITCHEN GARDEN.

B. W. POOR, Gardener, Highclere Castle, Newbury.

Broad Beans.—Make a good sowing of these at once upon a south border, or other warm situation. These Beans do the best in a heavy soil. Early Longpod is a first-rate variety, and should be sown in

rows 2 feet apart and 9 inches in the row. As a preventative from mice it will be well to coat the seeds with red-lead before sowing, and this may be easily done by putting these into a pail and sprinkling them with water, then with red-lead, and shaking well together. For exhibition purposes a few rows of Mammoth Longpod may be sown, and given a few inches more space in the rows. For small gardens, or where small Beans are appreciated, none is better than Beck's Dwarf Green Gem, sown in rows 1 foot apart. Early Mazzagan is also a useful sort for early use, and takes up but little space.

Forcing Operations in General.—A suitable quantity of material being in readiness for forcing hot-beds, a beginning should forthwith be made with beds for hastening early Potatoes, Carrots, Radishes, &c., to meet the spring and early summer requirements of the family. If the ordinary hot-bed frames are employed, the beds should be made from 3 to 4 feet thick, putting the materials solidly together as the work proceeds, as the heat is thereby rendered more lasting and less fierce. Let the beds have a margin of at least 1 foot all round the frames, but do not slope the surface much from the back to the front; the boxes being generally made with sufficient slope; and with a level surface inside, the application of water to the plants penetrates the soil more readily. In selecting varieties of Potatoes, give preference to such early varieties as come in quickly, and which possess short haulms; and Sharp's, Victor or Sutton's A1 are amongst the best of these. Plant the sets in rows 1½ foot apart, and 1 foot from set to set, and not less than 6 inches deep. An early variety of Radish may be sown thinly between the rows, although they do best when sown in a separate frame. The soil should be rich and light, and made fairly firm before planting; and if ordinary garden-soil be used, a good proportion of well-rotted leaf-mould should be incorporated with it. As soon as the tops appear above the soil, afford air freely on bright days and in mild weather, covering the glass securely at night. The soil for Carrots should be rich and light, preferably of a sandy nature, and if a small quantity of fresh soil be mixed with it, it will be improved; let it be 9 inches in depth, and fairly firm. Early French Horn is the most suitable for frame-work, and may be either sown broadcast, or thinly in drills, drawn at 6 inches apart, and rather less than 1 inch in depth. Thin the seedlings to 2 or 3 inches apart, afford ventilation at all times when the weather is favourable. If a few extra fine roots are required, every alternate row may be sown with Yentis's, Mollon's, or Sutton's Early Gem, and afterwards thinned to 6 or 8 inches apart. Continue to bring forward successive batches of Rhubarb, Seakale, Asparagus, &c. If a few roots of Rhubarb be dug up and placed in a warm shed, they give a supply for some weeks, and it is a much easier and better method than covering roots in the open ground. Sow Mustard and Cress every week or ten days, and do not cover the seeds with soil.

THE HARDY FRUIT GARDEN.

B. H. W. WARR, Rippleditch, Essex.

Planting Raspberry Canes.—The present is a suitable time to make new plantations of canes of last year's growth. Raspberries pay well for generous treatment, and delight in a deep, moderately light, rich soil. Plants that are allowed to occupy the same ground for more than five or six years gradually lose vigour, productiveness, in spite of being annually mulched. It is necessary therefore to make fresh plantations every few years in ground which has been trenched from 18 to 30 inches deep (according to the natural depth of the soil), and in which two or three layers of old butted or well-rotted stable-yard or other manure should be incorporated during the process of trenching. If the soil be of a heavy, clayey nature, liberal supplies of leaf-mould should be intermixed with it. The skillful cultivator invariably endeavours to correct and render the rooting-medium (soil) as congenial to the plant's requirements as possible. When the trenched ground has become settled, some selected canes should be planted, from 4 to 6 inches apart, in rows about 1 foot asunder, treading the soil pretty firmly about the roots in planting, and five or six at each end of the individual lines of canes. Lighter ones may be placed between to strain two sets of advanced wire upon, and to these the canes should be trained, and care taken to leave room in the ties of bast for the development of growth; and in case of a further settling down of trenched ground to allow of the canes subsiding

therewith, instead of being hung up, as would be the case when tied tightly to the wires. Then apply a surface-dressing of half-rotted dung, such as that from an old lot-hed, to the depth of 2 or 3 inches between the rows of plants. This mulch will preserve the soil about the roots in a more uniform degree of heat and moisture.

Varieties of Raspberries.—Superlative is a robust grower and a heavy cropper, producing extra large berries of fine quality; Carter's Prolific, Baumforth's Seedling, and Norwich Wonder, are also excellent varieties in all respects. Magnum Bonum is a good white-fruited variety, and Belle de Fontenay is the best autumn fruiting variety that I am acquainted with. The canes of the last-named sort should be cut to the ground now, or early next month, as the fruit is borne on the current year's growth.

Grafting Fruit Trees should be taken off, tied together and labelled; they may then be laid-in a few inches deep in soil until the time arrives for engrafting them on young stocks of the several kinds. The present is a good time to obtain seedling fruit-tree stocks, and to plant them 6 inches apart in rows 2 feet asunder. These may be worked in the spring and early autumn of 1898. Almond and Brompton plum for Peaches, Crab and Paradise for Apples, Apricot and plum seedlings for Apricots common Cherry or Mazzard for Cherries, Prunus lausasia and Myrobalan for Plums, and Pyrus communis and Quince for Pears.

THE APIARY.

The Laying of a Queen.—A queen can lay 3000 eggs a day, but not every day. Here are observations on a colony of bees I followed in Palestine from January to December, 1891. As nearly as I could make out, the colony numbered some 10,000 bees on January 1:—

Date.	Daily Average	Total.
January 1 to 20	100	2,000
20 to February 7	666	11,988
February 7 to March 3	700	18,800
March 3 to 18	2,333	34,995
18 to April 10	2,600	57,200
April 10 to May 21	1,900	10,000
May 21 to June 14	2,411	56,927
June 14 to July 21	2,277	50,904
July 21 to August 25	1,250	30,600
August 25 to 29	400	10,000
29 to September 12	200	1,600
September 12 to October 14	115	3,000
October 14 to November 11	75	1,000
November 11 to December 10	28	1,000
December 10 to 31	0	0
Grand total		329,024

About the same at the end of the season as regards the number—29,000 bees. At all events, the average is an average of 70 eggs a day for 355 days, or 12,600 eggs a day if we take the honey-dew season from March 3 to August 3. The colony did not swarm, and at the end of the season it was reduced to very nearly what it was in the beginning; 300,000 bees were hatched and passed away; the colony had produced nearly 180 lbs. of honey. This honey was taken by the extractor April 10; April 18, Orange-blossom honey; June 13 to 19, clover tree honey; July 10 to August 3, Thyme honey. *Bees & beekeepers.*

The coming Royal Show.—Bees and bee-products now form an attractive portion of nearly all the agricultural shows held in England, and at the Royal Agricultural show in particular, where everything in connection with bee-keeping may be seen. The *British Bee-keeper* announces that the committee of the British Bee-keeper's Association have been enabled to draw up a schedule of prizes which will, no doubt, bring forth keen competition, and impress upon the minds of visitors the great importance and extent of the bee-keeping industry throughout England. The great feature of the show will be a county trophy class, open to all counties in the United Kingdom, and as there will be £25 or more, one silver and four bronze medals, the class will undoubtedly be the most magnificent that has been seen in this country. Classes will also be included for leather honey in comb, and extracted, dark honey, hood-wax, honey-vinegar, and neat altogether five medals and 25 s. in money. As prizes will be offered for good samples of honey for 1897 and previous years, it would be well to hold any stock on hand if the quality is of the very best; but however good the quality might be, unless it is nicely kept, it will be not worth showing, and the price must in consequence be reduced to about one-half.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as advertisements and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unaccepted communications or illustrations, unless by special arrangement.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, JAN. 29 (Stockport Horticultural Society, Meeting.)

THURSDAY, JAN. 21 Linnean Society.

SATURDAY, JAN. 23—Royal Botanic Society.

SALES.

MONDAY, JAN. 18
Tuberoses, Spineas, Begonias, Greenhouse Ferns and Plants, &c., at Protheroe & Morris' Rooms.
Great Sale of Border Plants, at Stevens' Rooms.

TUESDAY, JAN. 19
Azaleas, Perennials, Roses, Paeonies, Gladioli, &c., at Protheroe & Morris' Rooms.
Japanese Lilies, 70,000 Tuberoses, Gladioli (Continental Plants, &c., at Protheroe & Morris' Rooms.

WEDNESDAY, JAN. 29
Palms from the Continent, 1000 Roses, Fruit Trees, Plants, Bulbs, Libanum, &c., at Stevens' Rooms.
Gloxinias, Clematis, Gladioli, Roses, Begonias, &c., at Protheroe & Morris' Rooms.

THURSDAY, JAN. 21
Imports of Liliums from Japan; Orchids, Border Plants and Roots, at Stevens' Rooms.
FRIDAY, JAN. 22 (Continental Plants, Roses, Lily of the Valley, &c., at Protheroe & Morris' Rooms.)

AVERAGE TEMPERATURE for the coming week, deduced from observations of Forty-three years, at Chiswick.—37.4°.

ACTUAL TEMPERATURES: LONDON.—January 13: Max., 42°; Min., 37°. PROVINCES.—January 13: Highest Temp., 46°; Scilly; Lowest, 31°, Stroudway.

The Horticultural Institute.

No one, we believe, doubts the widespread feeling that a horticultural institute of some sort is wanted in this country. Paris, Berlin, Vienna, Calcutta, Boston, Philadelphia, Ghent, and other cities possess a building suitable for the meetings of their principal horticultural societies. Those whose business it is to visit the Drill Hall or the Aquarium ask sometimes bitterly, "Why should London wait?" The halting response that was made to the scheme proposed by Baron Sir HENRY SCHROEDER supplies one reason why we have to wait, and we do not think, nor apparently do our correspondents, that the scheme proposed by Mr. WOOD in a recent issue has any better chance of success. But horticulturists nevertheless owe their thanks to Mr. WOOD for putting before them a scheme. We can hardly suppose the author himself can imagine that his complicated project, as it stands, can be carried out; indeed, he says he is quite prepared to find some parts of his scheme will require modification. Taken, then, as a basis for discussion only, Mr. WOOD'S scheme deserved attention. From it something more practicable may eventually be evolved. One thing, we think, is clear, no hall of sufficient dimensions to hold shows of the largest extent could be built in London with any chance of success. Even the Casino at Ghent is not large enough for the quinquennial shows, and annexes, tents, and greenhouses have to be supplied. If this fact be recognised, then it will be seen that a smaller hall than that projected by Mr. WOOD would suffice for ordinary occasions, whilst larger

shows might be accommodated elsewhere, as they are now. Round this smaller hall might be grouped rooms which would suffice for meetings of the minor societies, for the Lindley Library, and other horticultural purposes without the necessity for permanent exhibitions and shows of objects not relevant to horticulture, and which, we imagine, would quickly degenerate to the music-hall level. But even on this smaller scale, site, funds, management would have to be provided. Mr. WOOD says nothing about the site, but we do not think that would be an insuperable difficulty. As to the funds, we confess Mr. WOOD'S ideas seem to us more ingenious than practicable, and knowing by experience the difficulty there is in getting funds even for our horticultural charities, we have very grave doubts whether money would be forthcoming in sufficient amounts to maintain, much more to erect the structure. Then, as to the management, would or could the Royal Horticultural Society undertake such a task, and if it did, would there not be the usual amount of jealousy and criticism? and would not the special provincial societies do as they do now, to a great extent, hold aloof, and, as the phrase is, "run their own coach?"

In spite of these forebodings, which none would be more cordially glad to see annulled, than ourselves, we hope the central idea will be kept in mind. Free but relevant discussion will soon show what is practicable, and what is not—the ground will be cleared, and the duty of horticulturists to their profession will once more be put to the test.

Whatever we may think of Mr. WOOD'S scheme for a grandiose hall for horticultural purposes, there can not be the least doubt as to what our duties to the gardening charities are, and no one will question the propriety of the appeal which we have now the pleasure to lay before our readers, in full confidence that it will be responded to—

"The extraordinary event—unique in our country's history—of Her Majesty's completing in June next the sixtieth year of her beneficent reign, demands from us all, I venture to suggest, some special effort testifying to our deep thankfulness for the wonderful progress made in every way by our nation during the past sixty years, and for the many blessings, we now so freely enjoy. Animated by this feeling, the Executive of the Gardeners' Royal Benevolent Institution (of which our beloved QUEEN has been the Patroness for forty-five years) has determined to endeavour to celebrate so remarkable an occurrence by establishing a special fund to be called 'The Victorian Era Fund,' the income from which shall be devoted to affording temporary assistance to those applicants who are waiting to be placed on the Pension List, and who have been subscribers to the Institution, every friend of which it is confidently felt may be relied upon to do their utmost to help raise a sufficient sum the interest of which shall be devoted to the benefit of those who, when in a position to do so by becoming subscribers, did what they could to assist others. The Committee consider that a sum of at least £5000 will be required to enable them adequately to carry out what they propose; and this in addition to the amount required to meet the usual yearly outgoings of the Institution, which exceed £3000 (the sum paid at the present time in pensions alone being £2840). I, as chairman of the Committee, appeal to every gardener (and garden lover) in the country to aid us in raising this sum—

1.-t. By giving what he can himself, and urging his brother gardeners (and friends) to do the same.

2nd. By earnestly appealing to all lovers of gardens to contribute something to this object.

And I feel certain that if every gardener (and friend of gardening and gardeners) will do what he can, the proposal of the Committee will be fully realised.

"Any further information or details of the scheme will be most readily given either by myself or by the secretary, Mr. GEORGE J. INGRAM, 50, Parliament Street, London, S.W., who will also be pleased to forward to any applicant collecting cards or boxes.

"Earnestly begging you to give the matter your warmest support.

"I am, &c., HARRY J. VEITCH, Chairman of Committee and Treasurer."

Separate appeals will be sent to gardeners and to amateurs of all degrees, but the insertion of a word or two relieves us from the necessity of publishing both. The annual meeting is in progress as we write these lines, and the fifty-eighth anniversary festival dinner will be held at the Whitehall Rooms, Hotel Métropole, on Wednesday, May 26, 1897, the Right Hon. Lord ROTHSCHILD, in the chair. The following donations &c., are already promised:—

His Grace the Duke of Westminster, President ..	£100 0 0
The Baron Schöller, Vice-President ..	200 0 0
C. Czarnikow, Vice-President ..	50 0 0
N. N. Sherwood, Trustee (in memory of Emma Sherwood) ..	200 0 0
Harry J. Veitch, Treasurer ..	250 0 0
W. Sherwood (in memory of Emma Sherwood) ..	100 0 0
E. Sherwood ..	100 0 0
May Sherwood ..	100 0 0
George Munro ..	100 0 0
James Veitch & Sons ..	250 0 0
Thomas Bank Iron Company ..	21 0 0
A. Watkins ..	10 0 0
James Hudson ..	5 0 0
J. W. Selwin (Life Subscription) ..	10 10 0
J. Selwin ..	2 2 0

LINNEAN SOCIETY.—On the occasion of the meeting held on December 17, Dr. A. GUNTHER, F.R.S., President, in the chair; the President directed attention to the very handsome clock recently presented to the Society by Mr. FRANK CRISP, and now fixed over the doorway of the Meeting-room, and a cordial vote of thanks to Mr. CRISP was unanimously recorded. MESSRS. JAMES GREEN and J. H. GARDNER exhibited a series of sciaographs of British Batrachians and Reptiles in which the details of the skeleton were very sharply defined, and its relation to the external outline well shown. Mr. J. E. HARTING exhibited a supposed hybrid between the common brown hare (*Lepus timidus*) and the Irish hare (*Lepus variabilis*), recently obtained in Camarvanshire, where the latter species had been introduced in 1878. He compared the specimen in question with examples of both the above-named species, and contrasted their distinguishing peculiarities, pointing out the intermediate characters exhibited by the supposed hybrid. His remarks were criticised by the President, who thought that too much stress should not be laid upon external appearance and colour; that the question of hybridity should rather be determined by comparing the relative measurements of the leg-bones; and that the Irish hare should be compared in detail with the hare of southern Europe (*L. insularis* or *mediterraneus*). Professor HOWES drew attention to NATHAN'S observations upon the Peyer's patches of the Leporines, and pointed to the necessity for examination of the viscera. Mr. BARRETT HAMILTON, who was present as a visitor, was inclined to regard the supposed hybrid as an example of the ordinary brown hare turning white in winter, hitherto unnoticed in this country. Mr. THOMAS CURRY inquired what position the so-called Belgian hare or Leporine occupied in relation to the question of hybridity; and was answered that the popular notion of that animal being a hybrid between the hare and rabbit was fallacious, since it was nothing more than an overgrown tame rabbit coloured like a hare. Mr. E. B. WOODWARD gave a demonstration, illustrated with lantern-slides, of Mons. F. BERNARD'S

researches into the development of the hinge of bivalve shells. On behalf of Dr. A. J. EWART, a paper was read in continuation of one previously communicated by him, and entitled: "Further Observations on Assimilatory Inhibition." Mr. W. C. WOODSHELL gave the chief facts of a paper dealing with the "Development of the Ovule of *Christisonia*, a genus of the *Orobanchae*." Referring to Professor KOCH's detailed account of the development of the ovule of *Orobanche*, he remarked that *Christisonia* as a parasitic plant was of such interest, and differed so much in its vegetative structure from *Orobanche*, that it seemed to be worth while to record the facts of its embryological development. A brief description of

porium from a hypodermal cell; the casual occurrence of a double archesporium; the absence of tapetal cells; the division of the archesporium into four cells, the lowest of which subsequently grew into the embryo-sac; an anomaly was observed in one ovule, in which two of the uppermost cells persisted as rudimentary sacs, in one of which the nucleus had divided into four; the large size of the synergic, as compared with that of the corresponding cells at the antipodal end; the outgrowth of the embryo from the ovum as an elongated unicellular structure; the fusion of the polar nuclei; the early stages in the formation of the endosperm; the sequence of cell-divisions in the developing embryo,

"On the Chalcididae of the Island of Grenada, West Indies." This paper, communicated by Mr. F. D. GODMAN, F.R.S., F.L.S., dealt with the Chalcididae collected by Mr. H. H. SMITH, under the auspices of the British Association Committee for investigating the Fauna and Flora of the West Indian Islands. The collection consisted of from 600 to 700 specimens, and comprised six new genera and seventy-two new species, which were described. The geographical relationships of the group were discussed.

— The next meeting of the Society will be held on Thursday, January 21, at 8.0 P.M. precisely, when the following papers will be read — Dr. G. ELLIOTT SMITH, "On the Origin of the

FIG. 10.—ROSE GARDEN AT WALTON LEA, WARRINGTON. (SLE P. 39.)

the vegetative parts of the plant was then given; these were the rhizome-like, anastomosing network of roots bearing tubers at intervals, from which latter the exogenously-formed haustoria are produced. The haustoria penetrate the roots of the Bamboo or *Strobilanthes* upon which the plant is parasitic. The lateral roots and the stems are produced endogenously; the latter grow rapidly, and after producing the flowers die, at the end of the season. The flower resembles, in its main features, that of *Orobanche*. The ovary in one species is unilocular throughout, in another species it is bilocular below, and unilocular above; the placentae are two in number. By the aid of blackboard drawings the author then described the development of the embryo-sac and the embryo. This was shown to follow essentially the same lines as in *Orobanche*. Its main features were — the origin of the arches-

porium and the irregularity of these; the extremely rudimentary character of the embryo as compared with ordinary Dicotyledonous plants, this being perhaps even more pronounced than in *Orobanche*. Finally, it was pointed out that in a great many plants the vegetative and the reproductive organs have not always, by any means, a parallel development. A striking instance of this was to be seen in *Christisonia*. In this plant the vegetative structure was of a very abnormal and reduced type, and remarkably different from all other *Phanerogams*; while, on the other hand, the structure and development of the embryo-sac had remained essentially of the same normal type as in the majority of Dicotyledons. The paper was criticised by Dr. D. H. SCOTT, who testified to the importance and interest of some of the facts established. On behalf of Dr. L. O. HOWARD, entomologist to the U.S. Department of Agriculture, a paper was read

corpus callosa; a comparative study of the hippocampal region of the cerebrum of *Mur-nephth* and certain *Chiroptera*; Dr. J. GILCHRIST, "On the Minute Structure of the Nervous System of the *Mollusc*." Exhibitions — Dr. JOHN LEWIS, Fossil Antlers of Red Deer from the Cambridgeshire Fens; Messrs. H. and J. GIBBS, New Species of *Chara*; Mr. HOWARD MOSKOVSKY, New Variety of *Limnaea stagnalis* from the ponds at Howdon Fishery, Straling, N.B.

THE ROYAL GARDENERS' ORPHAN FUND
At a meeting of the executive committee held on the 8th inst. at the Horticultural Club, Hotel Windsor, Mr. WILLIAM MAUSWELL presiding, when the following special donations were announced — Altham Gardeners' Mutual Improvement Association concert, £50. 10s.; Mr. H. L. JONES, Ryecroft Nursery, Lewisham, box in Chrysanthemum Show House

£10 15s.: Reigate Chrysanthemum Society, £10; Scottish Horticultural Association, £5 5s.; Mr. J. H. VALLANCE, moiety of receipts for sale of flowers at the Bristol Chrysanthemum Society's Show, £5 5s.; Mr. J. B. STEVENSON, Chine Gardens, Bournemouth, box, £1 9s. 3d.; and Mr. J. DAY, Galloway, Garliston, N.B., box, £1 1s. The *bona fides* of the various children candidates for the prizes of the fund, thirteen in number, were examined and passed, and in consideration of the fact that the present year would see the celebration of the sixtieth year of the reign of the QUEEN, and also be the tenth year of the existence of the fund, the committee unanimously resolved to recommend to the general meeting that the *choix* of the thirteen candidates be placed upon the *Faund* without election. It was resolved that the annual general meeting should be held at Anderson's Hotel, Fleet Street, E.C., on Friday, February 19, at 4 P.M. The annual dinner will take place at the Hotel Cecil on Friday, April 30, Alderman Sir JOHN WHITTAKER ELLIS, Bart., in the chair.

BOTANICAL MAGAZINE.—The plants figured in the January number are:—

Aristolochia clypeata, André.—A handsome stove climber, of quaint form, and large, dull, purple-spotted flowers. Introduced from New Granada by Wallis; t. 7512.

Cynoglossum acrosum, Benth.—A West Himalayan herbaceous plant, with oblanceolate hairy leaves and loose branching spikes of blue flowers; t. 7513.

Berkheya Adami, Hook. f.—A very handsome Thistle-like plant, with heads of yellow florets. Native of the Transvaal, whence it has been sent by Mr. Adlam to Kew; t. 7514.

Croton Elateria, Bennett.—A shrub, native of the Bahamas, and interesting as being the source of Cascarella bark, used in the manufacture of incense, and for similar purposes; t. 7515.

Bignonia baccharifera, Mairet.—The B. cherere of Lindley. Native of Central Mexico, flowered at La Mortola; t. 7516.

"THE ROSARIAN'S YEAR-BOOK."—Rosarians look out for this little book, finding in it always something to interest them. The present issue contains a portrait and sympathetic account of Mr. C. J. GRABAME; an article on Tea Roses, by Rev. FOSTER MELLISH; and a similar one on hybrid perpetuals by Mr. PFEFF. The editor reviews the principal events of the past year, and the doings of the National Rose Society. Mr. GEORGE PAUL descants on the evolution of the hybrid Tea Rose. Mr. MAWLEY indulges his taste for statistics by tabulating the varieties that have most frequently received a medal from the National Rose Society. Out of 357 blooms of 81 varieties, it appears that "A. K. Williams" has received a medal twenty times, La France eighteen times, Mrs. John Laing seventeen times, and twenty-eight others have been "hemmedalled" from fourteen times down to twice. *Comice de Nadailac* stands first among Teas with twenty-six medals, and is well ahead of all others of its class. Mr. MAWLEY also contributes his usual notes of the weather from August 1, 1895 to July 31, 1896. It is a pity that this valuable record should not have wider circulation, as it interests not Rose-growers only, but all classes of cultivators, agriculturists or horticulturists.

ROYAL BOTANIC SOCIETY OF LONDON.—At a meeting of this Society, held last Saturday, Dr. ROBERT BOXALL in the chair, Mr. E. C. VAN NOTTEN POLE and Mrs. EDWARD SCOTT were elected Fellows, and the names of five others read for ballot at the next meeting. The secretary, Mr. J. B. SOWERBY, showed at the meeting stems of the Egyptian Papyrus, taken from the plant growing in the Victoria Water Lily tank at the gardens, which has this year attained extraordinary dimensions, forming a clump 7 feet in diameter, with stems 14 feet long, and 2½ inches at the base. From the white pith of which the stems are composed, the ancient Egyptians made a paper remarkable for its durability—simply slicing the pith up into flat strips, and laying them side by side until a sufficient length was obtained. Under pres-

sure the pieces adhered together, forming a perfectly smooth, even sheet, which could be written upon and rolled up without further preparation. He compared paper made in this way from plants grown in the gardens with a fragment taken from an Egyptian tomb, and, according to Dr. BINCH, at the least 2000 years old, the only difference between the two being the darker colour of the older specimen. Major COTTON said the plant, though once abundant, was now extinct in Lower Egypt.

FERDINAND VON MUELLER was a most indefatigable correspondent, says Prof. MACOWAN. If he could get any information on you, or if he could do anything for you, it was just the same—he gave you no peace till the thing was done. South Africa, from its similarity in climate to Australia, which he knew so well, specially interested him, and he prided himself, not unworthily, upon having been the means of dotting the tree-less plateaus of the Cape with the varied species of Eucalyptus, and our sandy flats with the Golden Wattle. In the course of a correspondence of some twenty-five years' duration with the writer of this memorial notice, perhaps the most characteristic letters were those expressing his enthusiastic delight at the success attending the acclimatisation of the *Atriplex Nummularia*, or Australian Salt bush, at Van Wyk's Vlei, from his little packet of half-a-dozen seeds by the care and assiduity of Mr. EDWARD ALSTON. And when, subsequently, he was informed that that gentleman had in one year distributed gratis two thousand pounds' weight of the seed of this best of black-fodder plants, his reply was a veritable psalm of rejoicing. Nor was the Cape by any means the only place to which his good offices extended. Wherever similar conditions of climate to those of Australia prevailed, he was sure to find out men like-minded with himself on cultural matters, and push the interests he had so much at heart.

BERLIN.—The oldest horticultural society of Germany, the Verein zur Beforderung des Gartenbaus in den Preussischen Staaten, will celebrate its seventy-fifth anniversary by a grand general exhibition to be held from April 28 till May 9, and in which foreigners are invited to take part. In the programme and its supplement, announcement is made of many valuable prizes, amounting to 50,000 marks (£2500), as well as many honorary prizes, amongst which is a very valuable prize offered by the EMPEROR. It would be of the greatest interest if British growers would exhibit on this occasion, especially Orchids, Chinese Primulas, Cyclamens, &c., to see if the English strains of the latter are better than the German. Entries must be made before March 1. Address to the Secretary-General, Berlin N. Invalidenstrasse, 42.

HESSDORFFER'S MONATSHEFTE.—The third number of the new German gardening paper *Hessdorffer's Monatshefte* has been recently published, and we notice with pleasure the interesting and valuable articles it contains. Besides many other articles, notes, and illustrations, it contains an extensive and exhaustive description of the new hardy Cactuses, collected by Mr. Purpus in Colorado, with three photographic illustrations taken from the collection cultivated by his brother in the Botanical Garden at Darmstadt. They have been kept outside for the last two winters without any covering, and are growing and flowering very satisfactorily.

ISLE OF WIGHT HORTICULTURAL ASSOCIATION.—The annual general meeting was held at Newport on the 9th inst. After the election of committee, &c. for the ensuing year, a short paper written by Mr. W. CUMMIS of Parkhurst Forest, Isle of Wight, on "Pruning Hard-wooded Trees" was read by the chairman, Dr. GROVES, B.A., J.P. There was a lively discussion upon the subject, as some of the district councils in the island are requesting people to cut their trees which overhang the highway. This, it is thought, will destroy the beauty of the island, and eventually its prosperity, which mainly depends upon visitors who are attracted

by the beauty of the island. The secretary introduced the association annumack, which met with much appreciation, and is likely to be of great benefit to gardeners, and to visitors to the garden Isle. Mr. J. MERRITT, gardener to H.R.H. PRINCESS BEATRICE, Osborne Cottage, staged two fine collections of Violets, of the varieties, Princess of Wales and Princess Beatrice; many of the blooms exceeded 1½ inch in diameter, and were awarded a Certificate of Cultural Merit.

THE PROCESS OF FERTILISATION formed the subject of an illustrated lecture by Mr. W. W. PERTREW, before the Cardiff Gardeners' Association, on January 5. The President (A. THOMAS, Esq., M.P.) presided over a company of about sixty members. A class for the study of botany was opened in connection with the Society upon the same date.

JUBILEE OF A NURSERY FIRM.—In 1847 the late Mr. JOHN WALKER established a nursery and seed business at Thame, Oxon. Though in his youth trained for the grocery trade, his love for flowers and their culture, and the success he achieved as an exhibitor indeed him, while remaining a grocer, to start a business as a florist, commencing with about twenty poles of ground and a two-light frame. Soon after he found it necessary to devote his whole time to the venture, and he was enabled in the course of years to build up an extensive business. On his death a few years ago he was succeeded by his son, Mr. STEPHEN WALKER, and this year witnesses the jubilee of the foundation of the firm.

"LA SEMAINE HORTICOLE."—While we are thinking of diamond jubilee celebrations, and preparing for a year of unwonted activity, our Belgian neighbours are very busy with the great exhibition to be held in Brussels, whilst the horticultural world in particular is stirred by the announcement of the issue of a new weekly horticultural journal, to be called *La Semaine Horticole*, and modelled on the plan of the *Gardeners' Chronicle*. The new venture will be issued on January 30, under the auspices of M. LUCIEN LINDEN, and with it will be incorporated the *Illustration Horticole* and the *Journal des Orchides*. We heartily wish our future contemporary a prosperous and useful career.

GHENT.—Certificates of Merit were awarded at the last meeting of the Chambre Syndicale:—To *Ondoglossum crispum* Petersii, O. Wilekemann albens, O. crispum macrophyllum, O. crispum regale, O. crispum album, and a group of new *Ondoglossum* species, all from M. JULES HIVE; to *Cattleya chocoensis*, from M. JULES DE COCK.

ALPINE PLANTS.—A "prix d'honneur" at the recent Geneva exhibition for alpine plants was awarded by the jury to M. H. CORBEVON.

"MY GARDEN DIARY."—Messrs. SUTTON & SONS, Reading, have published a dainty little diary under the above title. The title-page is very attractive, and the text of the book contains just the kind of hints the amateur wants. Good taste reigns throughout.

MORA NUTS.—Mr. CHRISTY, in his *New Commercial Plants and Drugs*, p. 12, publishes an account of the Mora Tree of British Guiana, based on SCHOUPEMACKER's paper in the *Journal of the Linnean Society*. The trees are remarkable for the wide buttresses which flank the lower end of the stem. Latterly, it appears, the seeds have been introduced as Cola-nuts, with which, however, they have nothing to do, neither do they contain Caffein. The Mora is a leguminous tree, by name *Dimorphandra* Mora.

THE NATIONAL DAHLIA SOCIETY.—At a meeting of the committee of the above society, held at the Horticultural Club on the 12th inst., the death of the late president of the society, the Rev. CHARLES FELLOWES, was announced, and a vote of condolence with his relatives was passed. Mr. T. W. GIBBS-STONE, the secretary of the society, having expressed a desire to retire from that office, he was unanimously elected president, and it was announced that Mr

WILLIAM ROBINSON had accepted the post of vice-president. Mr. J. FRANK HUDSON, Gunnersbury House, was elected hon. secretary, in the place of Mr. GRIDDLESTONE. In reply to a communication from the manager of the Crystal Palace, the committee resolved that in the event of the Crystal Palace authorities lending assistance, a special class, commemorative of the 60th year of Her Majesty's reign, should be included in the schedule of prizes at the next exhibition.

"**LE CHRYSANTHEME.**"—Those who would appreciate a clear and readable account of the Chrysanthemum, its history, physiology, and cultivation, should, if they have the chance, read M. H. DE VERNON'S essay on the subject. We say, if they have the chance, for the essay is not published separately, but may be read in the *Revue Générale Internationale Scientifique*, &c., March, 1896.

A GOVERNMENT ORCHARD.—The French, relates our contemporary, *The Bits*, of January 9, is the only European Government that maintains an orchard for the special cultivation of the Apple. It is in the garden of the Luxembourg, in a snug corner, and well protected by being completely walled in. Two hundred and fifty varieties are cultivated, and hither come the pomologists of France for cuttings. When the fruit in this Government Apple-orchard is ripe it is divided into four lots. The finest fourth is sent to the President of the Republic, and figures at the official dinners of the season. The second is for the Prefect of the Seine; the third for the Military Hospital in Paris; and the fourth goes to the large restaurants of Paris.

STOCK-TAKING: DECEMBER.—The closing month in 1896 tells a pleasant story in the pages of the Trade and Navigation Returns for December—our weekly record of the fall in grain quotations heralding the approach of a good record in the first week of 1897. Against a few and trifling items of decrease in importations has to be set the great fact that, as compared with December, 1895, there is a nett gain of £6,512,547; the total for last month being £43,503,595, as against £36,991,248 for December, 1895. Duty-free articles figure largely here—cereals showing the largest increase. Wheat shipments were larger by 2,325,400 cwt., and by £1,206,752 in value—the United States and Russia sending about twice as much as at the same period in 1895; flour (American and Canadian) showed an increase of £177,053; Barley was in excess by £229,000—this latter from Russia; and that country and the United States between them sent Oats to the value of £266,918 over last record. Maize being furnished by America and Argentina to the value of £269,000 over the amount for December, 1895. Apples went up £176,000; butter, mutton, and beef, show a great increase. In dutiable articles—tea went up £150,000; tobacco, £100,000 ditto; textile material increased £2,149,000, American cotton contributing £1,974,000—wool going up £511,000. But this is sufficient for the day. The following, from the summary table of exports, deserves its usual place here:—

IMPORTS.	1895.	1896.	Difference
	£	£	£
Total value ...	36,991,248	43,503,595	+6,512,347
(A) Articles of food and drink—duty free ...	11,672,910	14,864,039	+3,191,129
(B) Articles of food and drink—dutiable ...	2,228,222	2,901,614	+673,392
Raw materials for textile manufactures ...	8,204,731	10,355,139	+2,150,408
Raw materials for sundry industries and manufactures ...	3,116,211	3,521,781	+405,570
(A) Miscellaneous articles ...	1,315,159	1,990,889	+675,730
(B) Parcel Post ...	68,222	52,338	-15,884

Respecting sugar, whilst a Commission is inquiring into the causes of the falling off in the production of sugar in the West Indies, the planters out there are endeavouring to better their condition by placing their

eggs into more baskets than one, are adding to the number of their crops—various fruits as Oranges and Bananas, being now brought forward, with what success is not yet quite plain; the plan has already succeeded in Jamaica—a judicious selection will doubtless produce a paying result, the "capacity" of the United Kingdom for fruit being something astounding; and here may be given our usual excerpt from the figures relating to the imports of fruit, roots, and vegetables for December—

IMPORTS.	1895.	1896.	Difference.
Fruits, raw:—			
Apples ... bush	298,919	1,186,464	+788,545
Cherries
Plums
Pears	8,568	8,891	+323
Grapes	2,858	7,422	+4,564
Unenumerated ...	47,173	53,754	+6,581
Onions	48,747	432,235	+333,488
Potatoes ... cwt	32,395	32,147	-248
Vegetables, raw, unenumerated ... value	£77,901	£61,167	-£16,734

Surely, these items justify the above remarks respecting consumption; and we may now briefly allude to our

EXPORTS.

The figures for the last month in 1895 are £19,179,538; for the same month last year these are £20,291,296, showing an increase of £1,111,068; the only decrease particularly noted being 265,779 in metals and articles manufactured therefrom, except machinery. The chief gain is under the heading "miscellaneous manufactures"—the largest item out of the total of £431,000 is placed to the credit of cycles—the export value of which has increased by £139,000. Railway equipments show an increase of about £75,000 for the month. Steam engines went up by about £90,000. Mining and other machinery sent to South Africa and Australia show an increase of value, put at about £109,000. The East takes our cottons to the extent of £400,000 more than reported in December, 1895. American purchases in woollen goods, &c., show a decidedly upward tendency. The year's summary must be deferred for the nonce.

CHESTER PAXTON SOCIETY.—The opening lecture of the above society's syllabus was given by Mr. G. P. MILN, the hon. secretary, in the Museum, on Saturday evening last, the subject being "From Chester to Paris, *via* the Channel Islands, Normandy, and Brittany," with special reference to their horticultural resources. Mr. MILN'S treatment of the various incidents *en route*, and the methods of culture adopted, was most interesting and instructive, and the beautiful pictures taken by the way, and illustrated with the limelight, added much to a pleasant evening. Advantage was taken at this meeting of presenting to Mr. J. D. SIDDAL (the founder of the Society in Chester) with his photograph, subscribed for by the members as an expression of their thanks for the invaluable services which he has all along rendered to the Society.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The fifty-eighth annual general meeting of the members of this Institution was held on Thursday, January 14th, at "Simpson's," Strand, London. The principal business before the meeting consisted in the reception of the committee's report, and the accounts of the Institution for the present year, the election of officers for the ensuing year, and the election of twenty candidates to become pensioners on the funds. The report, balance-sheet, and the several resolutions were carried unanimously. Incidental mention was made that eighteen pensioners had died during the year, three of the widows continuing to receive the benefits of the Institution. The number of pensioners now on the list, 171, is larger than on any former occasion. A gratuity of 45 was allotted to each unsuccessful candidate; and comment was made on the excellent results obtained from the establishment of country branches at Exeter, Worcester, and other centres.

Allusion was also made to the great loss that the Society has incurred in the death of Mr. JAMES WEBBER. The committee reported that, "In consequence of Richard Brimblecombe of Exeter, aged 67, annual subscriber of £1 1s. for sixteen years; Henry Downing of Hitchin, aged 61, annual subscriber of £1 1s., also life member for twenty years; Thomas Easley, of Birmingham, aged 58, totally disabled, a life member for sixteen years, also contributed £7 8s.; Alfred George, of Dulleigh-Salterton, aged 69, annual subscriber of £1 1s. for sixteen years; Oliver Goldsmith, of Bookham, aged 63, annual subscriber of £1 1s. for twenty years; George James, of Binstead, Ryde, aged 67, annual subscriber of £1 1s. for twenty-eight years, also contributed £7 9s.; Richard Newman of Putney, aged 63, annual subscriber of £1 1s. for sixteen years; Thomas Pyper, of West Kensington, aged 78, annual subscriber of £1 1s., also life member for twenty-one years; Robert Squibbs, of Sleaford, aged 72, annual subscriber of £1 1s. for thirty-seven years; and Elizabeth Woods, of Clapham, aged 63, widow of the late S. A. Woods, annual subscriber of £1 1s. for nineteen years—being in distress, and having in every way complied with the regulations, these ten applicants be placed on the Pension List without the trouble or expense of election, in accordance with Rule III. s. 5. The above candidates having been elected unanimously a ballot took place for the remaining ten with the result given below. There were four candidates who applied for the fifth time, six for the fourth time, nine for the third time, eleven for the second time and nine for the first time; in all thirty-nine applicants. The following are the names of the successful candidates, and the number of votes recorded for each:—

JOSEPH MONK	3957
CHARLES SMITH	3762
WILLIAM MILNE	3651
EDMUND PAPWORTH	3285
DAVID DAVIS	3207
GEORGE ASHBY	3255
WILLIAM LIFE	3190
ELIZA WEBB	3107
THOMAS SIMMS	2831
RACHEL JEFFERSON	2802

The Annual Friendly Supper is being held as these pages are in the press, under the presidency of Mr. H. E. MILNER.

NEW PUBLICATIONS.—*Botanical Microtechnique*, by Dr. ZIMMERMANN. Translated from the German by JAMES ELIAS HUMPHREY, S.D. (Westminster: ARTHUR CONSTABLE & Co.) Laboratory students will welcome this, the latest treatise, on the chemical methods now employed by botanists to differentiate the several tissues and their contents, and render them more apparent. The various staining methods now employed are described as unimmemorable. Their importance may be estimated from the remarkable changes made evident by them in the growing nucleus, changes to which we are looking forward for the resolution of many of the problems connected with reproduction, atavism, and the production of sports generally. A chapter at the end is devoted to the methods of study of the nature and work of bacteria. Some tables, and a good index, complete a work which should find a place in every laboratory.—*The Fourth Report of the Department of Agriculture, New Zealand*, is mainly taken up with agricultural matters; but Mr. T. W. KIRK, the biologist, contributes some concise but excellent papers on the diseases of plants.—*Agenda Horticultor*, par L. HENRY, 167, Boulevard St. Germain, Paris. An excellent little handbook of reference for practical gardeners, whether novices or experts, provided they are acquainted with the French language.—*Essence of Flowers of Garden and Greenhouse*, by E. STEE and W. WATSON (F. WARNE & Co.)—*L. Chrysanthemum*, No. 1, Lyon, H. BOUYER.—*Revue Générale des Sciences*, Paris, 1896, 7th year, No. 23, Dec. 15, 1896, consacrée à la Tunisie, by MM. MAXIME CORNU and others.—*Bibliograph of the new Lepidopteran Contributions to American Economic Entomology*, by SAMUEL HENSHAW, U. S. Department of Agriculture, Division of Entomology. Part V., L. to Z., and

Index.—*Vinton's Agricultural Almanack* (for 1897). A year-book for farmers and landowners. *Agricultural Gazette Office* (VINTON & CO., Ludgate Circus, E.C.).—*Fourth Report of the (New Zealand) Department of Agriculture*, Wellington, N.Z.—*Dictionnaire Pratique d'Horticulture et de Jardinage*, 50th livraison. The authors of this book have got as far as the letters Pucc. in their valuable work.—*Catalogue des Graines et Plantes Vivantes offertes pendant l'Exposition, 1896-1897*. Jardin des Plantes, Paris. Applications for seeds or plants mentioned in this catalogue should be made before Jan. 15, to M. le Directeur du Muséum, 57, Rue Cuvier, Paris.—List of seeds collected in the garden at La Mortola, Ventimiglia, Italy (for private circulation only).—*Liste des Graines Recueillies par le Jardin Alpin d'Acclimatation*, H. CORREYON, 2, Rue Daucet, Geneva.—*A Dictionary of Birds*, by ALFRED NEWTON and HANS GADSDON. This is the fourth and last part of this treatise, including from Shearwater to Zygodactylis, together with Index and Introduction. (London: ADAM & CHARLES BLACK.)—*Atlas des Plantes de Jardins et d'Appartements*, par D. BOIS (KLINGSMECK, PARIS).—*Popular Bulb Culture*, W. D. DREY (UPVOTT GILL, 179, Strand.—*The Rosearian's Year-book, 1897* (BEMROSE & SOSS).—*Catalogue of African Plants*, collected by Dr. FRIEDRICH WELTSCHEIDT, Part I. by W. P. HIERN (British Museum, Natural History, Cromwell Road, S.W.).—*Annuaire Général Horticole* (Paris: 167, Boulevard St. Germain).—*Hesling's Monatsheft für Blumen und Garten Freunde* (OFFENHEIM, Berlin).

HYBRID CINERARIAS.

In consequence of the the discussion in *Nature*, some time ago, on the origin of the garden Cineraria, I was led to make a number of crosses among allied plants. The first set of six made between *Senecio multiflorus* (female) and pollen taken from colour-forms of the garden Cineraria, is now in bloom, and for various reasons is deserving of record. The plants are exceedingly handsome, and there is a strong predominance of the male parents in the colour and size of the flower-heads. The colours of the garden Cineraria have been transmitted almost unimpaired—the white centres are perfectly pure and not in the least confused by the rosy-lyle of the mother; while the deep blue-purple and maroons are still bright and similar, though toned down to some extent. One male parent was a magenta with white ring around the centre, and this ring in the offspring has disappeared entirely; but in the case of a lavender-tipped father the progeny are also white, with lavender tips. So strong has the influence of the pollen-parent been on colour and size, that the influence of the female requires to be sought for. A curious feature appears in many of the plants for which it is not easy to account; but I think from its character, and from its occurrence in 10 per cent. of the plants in flower, that it must be congenital. It consists in a spot or spots on several or all of the ray-florets, white in the case of pale flowers, and in the case of dark flowers formed by paler areas of the same colour. It is of no horticultural consequence for the present, at any rate; but one cannot help thinking that it shows a possible process in evolution. If it may be regarded in this way, we have here an original variation, produced by the crossing of distinct species, which, in proportion to its utility in attracting insects, would have a good chance of becoming fixed and intensified. It might be due in some way to the high development of the garden Cineraria, but nothing happens, in any case, for which there is not an original endowment in Nature. It may be noted that these spots occur in the first plant to flower of the reverse cross, in this case white on a maroon ground. The inflorescence departs somewhat in habit from that of the garden Cineraria, and from the point of view of an artist is much improved; being looser and more elegant. In some plants of one of the crosses, however, the inflorescence of the garden Cineraria is very nearly reproduced, but these are in small pots, and dwarfed in consequence.

Apart from the unexpected degree of dominance of the male parent, in the colour and character of the flower-heads, the plants are all very nearly intermediate, and there is no remarkable variation between them. In height, the progeny tends rather to favour *S. multiflorus*. The auricles at the base of leaf-stalks are very nearly in shape like those of the garden Cineraria, especially at the base of the plant, but the degree of dentation appears to be less. The reduced lateral leaflets of *S. multiflorus* have almost entirely disappeared, but about 32 per cent. of the plants show definite indications of them. In the shape of the leaf-blade and in the hairiness of the under-surface, appearances are as nearly intermediate as possible. The involucre vary in hairiness considerably, but there is a general agreement in plants of the same cross; and, as the garden Cineraria varies considerably, I take it that the degree of hairiness has been governed by the male parent. This dominance probably belongs to the garden Cineraria as such, and not to sex, because a plant of the reverse cross, of which I am not now treating, is coming out with flower-heads of clear white in the centre, with deep maroon band, and not at all affected by *S. multiflorus*. Burbridge draws attention to this dominance of one species over another, whichever way the cross is made, in his *Propagation and Improvement of Plants*, p. 122, but I do not find that it is recognised by Bailey in his *Plant Breeding*, and notes of the occurrence appear to be few. Professor Henslow in his paper on Hybrid Rhododendrons in the *Journal of the Royal Horticultural Society*, vol. xiii., p. 249, referring to the assertion often made that a hybrid resembles the male parent in the flowers, and the female parent in foliage, says, "It would be more correct to say that the offspring may resemble either parent in either way and in various degrees, according to some unexplainable propensities in them respectively," and, further on, writing on the form of the corolla of the hybrid or cross in Rhododendron, gives an instance of this propensities. "Thus the small-flowered *R. multicolor* and its variety, Curtisii, invariably brings down the size of the corolla of the larger-flowered species with which it may be crossed, whether it is used as the male or female parent, to some approximation to its own in the offspring." Mr. Burbridge kindly gives me the instance of *Nepenthes Radicans*, which always seems to be procreant, either as male or as female. As he suggests, instances are no doubt numerous.

I have now to explain the *modus operandi* of making these crosses: The heads of *Senecio multiflorus* were covered at an early stage, in small groups, with a shia, in order to exclude insects. When the organs were in proper condition the pollen of the best forms of the garden Cineraria was brought, each to the heads of the intended bag, and a label applied accordingly. No further precaution, judging by results, appears to have been necessary. If anything had gone wrong, it must have been that pure *S. multiflorus* would have come from the seed saved; but in no case has this happened, and therefore it may be assumed that *S. multiflorus* is sterile to its own pollen—at least, to a considerable extent. The heads are protandrous, and a good state of the pistil must arrive before the pollen can be applied. The progeny of each cross repeats the colour of the pollen-parent so nearly as to confirm the label in nearly every case.

These hybrids have, of course, no immediate bearing on the origin of the garden Cineraria, and it remains to be seen whether it can be touched by others yet to flower. I feel sure, however, that no investigation can be complete without the evidence of *S. Tussockianus*. Unfortunately it is not in cultivation, and I should be extremely grateful to any reader of the *Gardeners' Chronicle* in the Canaries who would be so kind as to send me seed. It is especially desirable also to receive a fresh wild stock of *S. cruenta*, because I think we have not now the best possible form. It appears to me that some of the wild relations of the garden Cineraria are not too perfectly represented by books

and specimens, and I should therefore receive very gladly any seeds from allied plants of herbaria habit. It would be of interest to possess more complete information on the relative distribution of the kinds, and of the areas they occupy. If any two grow within reach of the same individual insects, it appears inevitable that they must cross, and the facility with which crossing takes place is proved by the fact that not one of the thirteen crosses I have attempted has failed to produce a hybrid. *R. Irwin Lynch, Botanic Gardens, Cambridge.*

PLANT NOTES.

CHRYSANTHEMUM NIPPONICUM.

This Japanese species was described in 1872 by Franchet from specimens collected in Nippon by Savatier, where it is wild, and is also cultivated for the sake of its large, handsome flowers. It is a perennial shrub, about 2 feet high, with numerous stout branches clothed with fleshy oblong-spatulate, toothed leaves, and bearing numerous erect stalked flower-heads, the latter 3 inches across, the disc large, turbinate, yellow; the ray-florets broad, overlapping, and pure white. It is allied to *C. arcticum*, and our native *C. leucanthemum*, the Ox-eye Daisy. There are examples of it at Kew, obtained from Messrs. Dunham & Co., Naples, and from the Yokohama Nursery Co., in whose catalogue it is offered under the name of *Leucanthemum nipponicum*. It is quite hardy, but the stems are killed down by frost. The flower-buds set freely, and there was a good promise of flowers this year, but the first snap of frost destroyed them.

According to an account published in *Mittheilungen Deutsche Garten Zeitung* by Georg Marquardt, Zossen, this plant is a useful winter-flowering shrub for the greenhouse. He recommends that the cuttings should be put in during April, in a close frame, where they root in about a month. They should then be grown on in pots under the same treatment as the common *Chrysanthemum*, or planted out in a sunny border, to be lifted and potted in autumn. In a cool house the flowers expand in December and January, when they are of the great value both for the conservatory and for the supply of cut flowers. *H. H.*

HEYWOOD.

THE residence of Lord Justice Lopes, is beautifully situated near the range of Wiltshire Hills at Westbury, and stands in its own park of some 100 acres or more. Its extent cannot be accurately estimated by sight from its undulating character, and the interception of the many large, spreading and handsome trees that abound. Among these are many Elms of enormous size, which tower up to great heights. Oaks, though not so numerous, are nevertheless of large dimensions, one specimen standing near the house has tempted the timber merchant to proffer a large sum for it, but without avail, Lord Justice Lopes setting too high a value on its presence as a landscape object to part with it for its mere commercial value. There are many other trees of interest in the park, notably some Horse-Chestnuts, one having a spread of branches 85 feet, and being otherwise well proportioned; also Sequoias (Wellingtonias) and Thorns.

The house is approached through two entrance lodges, the one occupied by the gardener (Mr. W. Robinson) having a foreground of tall trees, a pleasant aspect and comfortable appearance. The house standing as it is does on high ground, commands extensive and very pleasant views of the Westbury Hills and surrounding country.

The pleasure-grounds, which are 7 acres in extent, are well furnished with shrubs and ornamental trees, the beds of Laurel are kept neatly trimmed, and thoroughly under control. Of the evergreen trees there are some nice specimens of *Abies Nordmanniana*, *Thuopsis dolabrata*, *Cupressus Nootkatensis*, *Sequoia gigantea*,

Cryptomeria elegans, *Abies Pinsapo*, *A. cephalonica*, *Pinus austriaca*, *Cupressus Lawsoniana*, and a fine old specimen of *Weymouth Pine*. There are also some large copper Beeches, but undoubtedly the feature among deciduous trees is the very fine *Catalpa*, which stands on the steeply sloping lawn between the house and lake. This is probably one of the finest in existence. It has a diameter in branch of 60 ft., and its limbs, which are proportionate to its great breadth, rise directly from the ground-line, and are supported by strong iron bands and chains, as well as heavy forked timbers for carrying the horizontal branches. Its age must extend considerably over a hundred years. It has, I believe, a history extending through three generations of the Judge's family, and its increasing

vantage of a substantial glass coping, and this, with the natural shelter furnished by the lofty walls, and a belt of trees to break the north and east winds is sufficient, without movable front blinds. The crops of Peaches every year are splendid, both in point of size, numbers, and colour, and reflect much credit on Mr. Robinson, who personally undertakes the work of pruning and nailing. Many of the trees, too, have been planted by him, as well as numbers of Apples and Pears. The varieties of Peaches grown comprise such excellent ones as *Sea Eagle*, *Bellegarde*, *Violette Hative*, *Dymond*, *Goshawk*, *Condor*, *Wallerton's Admirable*, and *Princess of Wales*; and of Apricots there are the well-known *Moor Park*, *Breda*, *Houns-Eirk*, *Royal*, *St. Auboise*, *Shibley's*, and *Kaisha*.

annual crop from six trees number 500 fruits, the varieties being *Stirling Castle*, *Sea Eagle*, and *Bellegarde* Peaches; *Lord Napier*, *Pittmaston Orange*, and *Humboldt Nectarines*. *Brown Turkey Figs* occupy a portion of the back wall, and furnish some fine fruit during August and September. Melons, Cucumbers, and Tomatoes are grown in other houses, and at the time of my visit there was ripening a heavy crop of some fifty medium-sized Melons in one small house. About 550 Strawberries in pots are grown in about four sarts, and it is doubtful if there are any better samples of *Augusta* Nivea sent to London during the season than those from Heywood. Many of the berries weigh from 1½ to 2½ oz. each, and there are practically none less than an ounce of this variety.

FIG. 11.—CHRYSANTHEMUMS DURING THE SUMMER MONTHS AT HEYWOOD. (SEE P. 48.)

age and size have a due appreciation from its present owner. It flowers profusely each year, and appears to be as healthy as it could have been at any period of its life. It has been an object of interest to the landscape photographer on more than one occasion.

The kitchen-garden, which comprises about 3 acres, closely adjoins the house and pleasure-grounds, is well stocked with espalier, bush, and pyramidal trees of Apples and Pears, while bush-fruits and Strawberries are grown in proportion to the demands. Plums, Cherries, and cordon Pears occupy wall space on east, west, and north aspects, the south being devoted to the culture of Apricots and Peaches, which are well grown at Heywood. For Peaches, there is a 50 yards' run of wall, and the same amount of space is devoted to Apricots. Standard and dwarf-trained trees are arranged to every useful inch of space is occupied. Both crops have the ad-

Only the best kinds of Apple and Pears are planted, and these produce fruit of good size and quality.

A handsome range of forcing-houses, 48 yards in length, was built a few years since for the growth of early and late Grapes, and early Peaches, another large cool house being devoted to midseason Nectarines, Figs, and Peaches. Grapes are very well grown, particularly Muscat of Alexandria, Madresfield Comit, and Lady Downes. Black Hamburgs have a house to themselves, with the exception of one rod of Madresfield; so, too, have Muscats, and these produce fine bunches, brightly coloured, and having large berries. Lady Downes, in the late house, were excellent in every respect. Two small divisions are devoted to the earliest Grapes and Peaches; and here, as in all other departments, there is abundant proof that the one in charge is a practical man, and is thoroughly supported by an appreciative employer.

In the cool Peach-house, previously mentioned the

Royal Sovereign, too, does well as an early sort in pots.

A varied assortment of decorative and cut-flower plants is grown to meet the demand of the house and conservatory. Tuberosus Begonias, zonal and other Pelargoniums, Bouvardias, double Primulas, Poinsettias, Azaleas, Allamandas, Stephanotis, Celsias, Anthuriums, Tea Roses, Coleogynes, are some, among others, well grown; Palms, Crotons, Dracenas, Eulalias, Pandanus, are a few among the various ornamental foliage plants. A house is devoted entirely to Ferns in pots, and these make a dense mass of fronds during the summer and autumn, completely hiding their pots and the stages on which they stand. The conservatory yields *Camellia* blooms in abundance in their season, as well as Orange blossom and fruit in quantity; and the side stages accommodate a portion of the *Chrysanthemums* in winter, for which Heywood has a local fame. The

owner takes a great interest in these, and his collection is kept quite up to date in point of variety. About 450 plants are grown, principally for large blooms, and sixteen 1st prizes have been won at exhibitions during the past season. Our illustration on p. 47 affords a good idea of the vigour with which the plants grow.

There is no lower-garden proper at Heywood, but the borders in the kitchen-garden provide a wealth of useful flowers for cutting. On the sides of the small garden-pond, which occupies a central position, summer flowers are grown, and two very large specimens of the pigmy Spruce, *Picea excelsa* var. *pygmaea*, are quite at home, and have occupied the borders for many years—so many that no record is known. They are very fine specimens. *H. S.*

NOTES ON THE SEASON OF 1896, ISLEWORTH, MIDDLESEX.

The first two months were temperate, and the period March to July (inclusive) above the average in temperature. The whole of these seven months were very dry, with the exception of a seasonable rainfall in March. The last five months were cold and wet. The average maxima for the whole year amounted to 57°; the extreme maxima 93°, and the extreme minima 27°. The rainfall measured 21.44 inches. The night temperatures during the summer were generally low, and the extreme monthly minima in no case exceeded 34°.

A temperature of 70° was reached on seventy-seven days, and frost occurred on fifty-seven nights. There was no severe cold during the year, and snow was only visible on two days.

The period of drought that began with the advent of April, and lasted into August, proved very destructive on these dry soils; and the torrential rains of September ruined quite one-half of the fruit that had escaped the vicissitudes of the spring and summer.

Vegetables.—A great deal of disease was apparent on the main crop and late varieties of Potatoes, which made a stunted growth in the first instance, and a secondary growth in August and September. The earlier varieties were free from disease, and produced a heavy crop of undersized tubers.

Pears were very difficult to deal with on account of the intense drought, and misdirected efforts have resulted in a great increase in the sparrow plague recently. Lettuces "bolted" early, and the intense heat of the surface-soil prevented the summer sown seed from germinating in time to produce a winter crop.

Fruit.—Pears and Apples bore generally heavy crops (especially the early Apples). Flavour of course varies from year to year. This year Cox's Orange Pippin was far superior to Ribston Pippin. Among the Pears, the old Burreé Bose was again triumphant over all others. Marie Louise suffered from some difficulty in seed production. I fail to find any really matured seeds, and a large crop rotted off wholesale from premature decay of the pips. The few fruits that were pipless remained sweet and sound many weeks after the others had perished.

The wall Apricots bore fine crops, and the Strawberry crop was large in quantity, but the fruits were small in size and inferior in flavour. My one Quince tree was overweighed with an immense crop. Against this the Gooseberries, Standard Plums, Cherries (dessert), and Brambles (of sorts), were absolute failures owing to the drought. Currants had a heavy crop, but were badly blighted. Wall Peaches (outside), carried a fair crop of rather undersized fruit, but fully one-half was raised by five consecutive days of incessant rain early in September, just when the bulk of the fruit was ripe. Filbert and Cob-nuts a small crop. Walnuts fair crop.

Flower Garden.—This proved a year of disappointment mingled with some surprises. Thrips and earwigs were a plague until the September rains came. I noticed also a fly which laid eggs in the blossoms of the Begonias, and the small maggot when hatched, caused the blooms to fall early. The so-called rusty Begonia disease is, I think, caused by the intensity of our mid-summer sun, combined with an arid air and

too high day temperatures. It never seems to affect late-flowering Begonias, or those grown in moderately shady positions out-of-doors. Early in the year the April drought afflicted the border Narcissus, and later on the Roses and Japanese Lilies proved very unsatisfactory, with the exception of those which flowered very late in the season. Zinnias were a complete failure, with the exception of *Z. Haageana*, which stood the drought well. Sweet Peas and annuals generally failed altogether, except the favoured few that received exceptional attention in watering. On the other hand many Cape plants revelled in the hot soil and burning suns of May, June, and July, and bloomed in profusion.

The great bulbs of *Brunsvigia Josephine*, always uncertain of blooming in this country, all, with few exceptions, threw up their sturdy flower-scapes. Those in the open took a far more brilliant colour than those under glass, and not only lasted long in flower, but withstood the rains and winds of September without damage. *B. Cooperi* also took a very brilliant colouring outside, and flowered freely. *Lycoris squamigera* both wintered and flowered finely outside against an unheated wall, without any protection.

Gladiolus Lemonei flourished admirably, but some of the species refused to make any growth until September.

Seedling Dahlias (naturally later in being planted out than old plants) did very well, but those planted out early failed.

Onocidium incurvum flowered very finely in the open all July and August, and stood the weather without any injury to the blossoms or bulbs.

Evergreen Conifers suffered much in the period May to August, especially Wellingtonias, *Arancarias*, and *Lawson Cypress*; but Cedars (including the malignant *C. Deodara*) were unharmed. The French Flint-glass Bottle Company's system of fruit-protecting has proved very satisfactory for Apricots, Morello Cherries, and some kinds of Plums; also for straws. There is no real difficulty in the process. *A. Horsley, Maadville House, Isleworth.*

CYPRIPEDIUMS IN BRUSSELS.

Our illustration fig. 12, p. 49, shows a view in one of the *Cypridium*-houses in St. Lucien Linden's newly-established nursery at Montrebecq, Brussels, recently alluded to in our columns. More than 5000 flowers of *C. usneae* and its varieties were open at the same time, which produced an astonishing display. Specimens illustrative of fifteen varieties were to have been exhibited at the Royal Horticultural Society's meeting on Tuesday last, but were delayed in transit, probably in consequence of the fog.

HOME CORRESPONDENCE.

PEARS OF GOOD AND BAD QUALITY.—Every season the merits of some particular Pear are brought before the readers of the gardening papers, some of which are due to climate, some to soil, or the nature of the season. This shows it will do to depend on a very limited number of varieties, as some gardeners are inclined to do. To the market-grower this may not matter, as he cultivates those which he thinks will bring in the best returns, regardless often of quality; but with the private gardener it is far otherwise—he must supply dessert and kitchen fruit of good quality for eight months in succession, and the more varieties the better are his chances of obtaining satisfactory crops. In recent issues of the *Gardener's Chronicle*, favourable mention was made of Hynshe's Victoria Pear, a variety of which I have a tree trained on an east wall, where it is perfectly worthless, the soil being too retentive, and therefore too cold for it. It never fails certainly to produce a crop of fruit, but the quality is very poor. It is a Pear that is not suited for a cold, clayey soil in Yorkshire. [Have you tried it upon the Quince stock? Ed.] Glou Morgan in the same soil, but on a west wall, brings fruit of fair quality most years; this year, however, it failed to fruit. That favourite old variety, *Conseller de la Cour*, which is here a sure cropper, and of excellent quality, although it

ripens too close on the heels of Marie Louise. This variety is so seldom mentioned by writers, that I am led to believe the favour in the south is not so good as here. I should be interested if some of your readers would relate their experiences with it. I was glad to see that your contributors, on p. 763, for December 19, were so obliging as to give at the foot of their notes the part of the country they reside in. *J. Easter, Nottell Priory Gardens.*

AN EARLY VIOLET.—One of the very earliest to bloom is the Yellow Arkwood Gem, old in point of time, but to be grown for years to come by flower-gardeners, on account of its tufted growth, earliness, freedom of bloom, and persistence. It is of a clear sulphur tint, and this useful variety has, by means of sports, originated two other most useful bedding varieties, viz., Goldfinch, yellow, distinctly edged with pale purple, and this in turn sported to Duchess of Fife, having a light primrose ground distinctly edged with blue—a charming variety. It was recently stated by a leading authority on Violas, that there are three epoch-making types among them, one, and the earliest, is *Mægrie*, which the late Mr. John Fleming used to employ with such admirable effect at Cliveton, and which it is believed has never exactly reproduced itself from seed; *Duchess of Fife*, which is well denominated a leading flower, for it finds admirers on every hand; and *Iona*, the leading *Viola* in 1894, a combination of lavender-and-blue back, with a white blotch on each of the lower petals—a most distinct and striking flower of marked individuality of colour. *R. D.*

POLYGONUM BALDSCHUANICUM.—I have read with pleasure the remarks concerning the above plant, without doubt the most delightful species of the genus. The plant may be fairly described as a climber, or at least a twiner, which, from a garden point of view, gives it additional value and interest, for the growths readily twine round any other body which may be near it, and in this way a number of growths of from 12 to 18 feet in the season is made. During the past season a very fine example of it was for a long time quite a feature, flowering in the herbaceous department at Kew in one of the beds opposite to the small alpine-house. I was at the time much struck by its beauty, and its value as a hardy climbing plant. The example at Kew very much resembled that figured in the *Gardener's Chronicle* on p. 17, but it is scarcely possible adequately to describe the beauty of the plant. If memory serves me aight, a few twiggy sticks of some 8 feet high had been provided for it, to the summit of which it quickly attained, then, for want of any further upward support, the growths had toppled over all around in a neglected fashion, forming a beautiful head, the stems for several feet being wreathed with its paucity of white blossoms, faintly tinted rose-pink. It is just the plant for placing at the base of a specimen of Wellingtonia, for, with its branches left as long as possible on either side, would afford just the support it requires. In an out state it is equally charming, for its pretty hastate and rather glossy leaves display its pleasing panicles in a most effective manner. *E. Jenkins.*

QUEEN'S DIAMOND JUBILEE.—Whatever may be the fate of the proposed Horticultural Institute—and it would not appear to be a very rose-hair one—looking at the practical outcome of the horticultural hall scheme started under such influential auspices a few years since, there is one way, within the reach of the humblest amongst the horticultural community, of worthily commemorating the Diamond Jubilee. Here it is: Let the gardeners of the United Kingdom combine to raise, for this year at least, the quarterly grant to the poor little ones at present enjoying the benefits attached to the Gardeners' Orphan Fund. The gardeners did a noble thing in instituting this excellent charity in 1872, and they might do a good work in 1897, and it can be done with very little self-denial, if every gardener in the country will embrace the opportunity for doing good that such a memorable occasion suggests. To those knowing anything of the children on the fund, it is common knowledge that the 5s. per week allowed to the particular child has (in many cases) to do duty, owing to the distressed circumstances of the widow, amongst the other members of her often far too numerous flock. The 5s. should be confined to the child elected—it is little enough, in all conscience; and stern poverty steps in and decrees that in spite of any rules which committees may make, they must often be inevitably disregarded by the higher and more pressing claims of Nature. It is not too late

now for the executive of the Fund to organise a card collection amongst the gardeners of the country, and to have the returns by Celebration Week. Will it take the hint here thrown out in a kindly and good-meaning spirit? Necessarily, the majority of the reopenings, &c., incidental to the Commemoration of the Diamond Jubilee will be practically confined to adults; in this particular case gardeners will have a grand opportunity of making a noble exception. May they at once embrace it. *J. B.*

HOME OF HORTICULTURE.—The letter from Mr. Douglas in your issue of January 2 deserves a reply, emanating, as it does, from one of our best-known and most respected horticulturists. Mr. Douglas dwells upon the unsuccessful efforts which have been made in the past to establish a home for horticulture. They all prove that horticulture single-handed is unequal to providing a suitable home for itself; and

shows, such as the National Chrysanthemum show and similar exhibitions, can be conveniently held? To relieve Mr. Douglas from undue anxiety, I hasten to assure him that we do not "ignore the lessons to be learnt from previous failures," but hope to profit by them. These failures prove that a combination of all the other sciences with horticulture is impracticable; also that horticulture alone is not strong enough to provide its own home; hence the only alternative is to unite such as will live happily together (under the auspices of the Royal Horticultural Society) and prove an attractive combination. Our continental neighbours—so far in advance of us in this matter, to our disgrace, be it said—have proved that horticulture and the fine arts may be associated to their mutual advantage. No one knows better than Mr. Douglas the necessity for providing different houses for different classes of plants. Horticulture requires suitable surroundings, and will not

upon second thought, Mr. Douglas may not see very much to laugh at, either in the state of the benevolent funds or in any effort to augment them. *James L. Wood.*

THE LATE MR. JAMES WEBBER.—No doubt to many gardeners or general readers of the *Gardeners' Chronicle*, Mr. James Webber, whose lamented death you last week recorded, was a very successful salesman of garden produce, and no more. To many others, however, he was well known for his active work in connection with gardening charities. To too few probably was he known as a very earnest and unselfish reformer of our market habits and customs, especially in relation to fruit. With the exception of Mr. George Mouro, who was a very sympathetic co-operator with Mr. Webber, no other Covent Garden salesman ever attempted to do so much to promote reform in fruit-packing for market sale as he did.

FIG. 12.—CHRYSANTHEMUM-HOUSE IN M. L. LINDEN'S NURSERY, MOODLEBECK, BRUSSELS. (SEE P. 48.)

that a combination of all the other sciences with horticulture spells failure. I venture to say that such a result might have been foreseen as inevitable; for such projects, despite the pomp and ceremony which attended their inauguration, and the "great flourish of trumpets," which Mr. Douglas particularises. He, however, adds, that this usually accompanies unsuccessful horticultural schemes; and here I would remark that a very great flourish of trumpets will be required to herald Mr. Douglas's Temple of Horticulture (formed after the similitude of the "Drill Hall of the London Scottish Volunteers in James Street, Westminster," "a building on a modest scale, not for large flower shows"), when he lets us see his plans, because such a scheme would be predestined to failure, and therefore should have a great flourish of trumpets like its unhappy predecessors. A building for large shows is precisely what is now so urgently demanded, and nothing short of this will meet the requirements of all interests. This was most forcibly stated by Sir Trevor Lawrence, Bart., and also by J. A. Bevan, Esq., at the Jubilee Chrysanthemum banquet. Perhaps Mr. Douglas will suggest where the large

thrives amidst the glanour of a music-hall, nor in the company of shooting-galleries and Punch-and-Judy shows. This may serve in some measure as a reply to his remarks as to the Aquarium. The ill-fortune that has attended the Alexandra Palace is proverbial, and it is therefore weak to mention that place in this connection. I have brought forward a scheme based upon the experience of our neighbors, and have suggested that the fine arts might be probably associated with horticulture. My opinion remains unchanged, and I await the publication of some better projects from those who have so freely commented upon my own. Mr Douglas's flight of fancy into the region of exhibitions, where he sees exhibitions of kid gloves, state carriages, matches, &c., is of course very fine; but upon his descent to this sublimary sphere he will perhaps allow that his imagination has played him false in this instance. The only explanation for such a remarkable idea is to be found in the reference which I made to a three days' festival in aid of the benevolent funds; but kid gloves, state carriages, and matches, were in no wise contemplated or even hinted at. Perhaps,

Mr. Webber's efforts were not limited to the giving of good advice. He did for several years alone, and later in conjunction with Mr. Mouro, offer at some of the London exhibitions, but especially in connection with those of the Royal Horticultural Society, valuable money-prizes in furtherance of the object he had in view. Like some of his market colleagues, but in a very practical way, Mr. Webber realised how much loss resulted to home growers of fruit because of their very defective market methods of packing. It was natural enough that any man of ordinary feeling, and of a sympathetic nature, should realise the grave deficiencies of our home methods as compared with the much better ones of the foreigner; our superior home grown fruit being, by its bad packing, heavily handicapped in the market. Since Mr. Webber's prizes originated in what now seem to be the far off South Kensington days of the Royal Horticultural Society, very great progress has been made, especially in relation to soft fruits, and to an appreciable extent with Apples and Pears; although much yet remains to be done by the rank and file of growers. I always found in connection with the judging of the classes for

which Mr. Webber's prizes were offered, much more interest than related to the judging of ordinary fruit classes. Mr. Webber invariably assisted at the function, and would, in making awards, always give reasons for so doing. He was not easy to please, because he had good ideals, and wished to see them realised practically. The earlier classes were instituted prior to the introduction of that wonderfully popular and excellent packing ingredient, wood-wool, and cotton-wool were the chief elements employed. That material largely gave to the judges satisfaction. Mr. Coleman, of Eastnor, was, I think, the first to introduce soft, sweet, clean moss, especially for Peaches, and this material was greatly liked. It was not, however, equal to wood-wool, a material that everyone could have at disposal, whereas moss needed considerable cleaning and preparation. Now wood-wool, which is so cheap, places all on an equality, although even that does not make skill in packing always equal. However, great progress has been made all round. No doubt, it would be a pity were packing classes for all descriptions of fruit entirely without any exhibition included, for the best examples do offer to young growers very useful object-lessons, and invariably they create great interest. We must not forget that, much as things have improved, there is yet great room for further development. Neither should we forget that in this valuable work few men have been such earnest pioneers as was the late James Webber. A. D.

POTATO DISEASES.—On p. 13 of the *Gardeners' Chronicle* for January 2 ("Potato Terentynus"). Professor Johnson is reported to have stated "that the fungal filaments (the mycelium of the *Phytophthora infestans*) in the tubers, &c." (of the Potato), "do not die, but rest in the tuber during the winter to germinate with the advent of the following spring, and to spread disease in the newly-formed shoots;" and then he warns us that diseased Potatoes in consequence should not knowingly be used as seed. Has this theory been fully established by our scientific men and experimenters? I ask this question, as for a long time there has been great controversy upon this subject, and it is of the utmost practical importance to us who cultivate the Potato, and Professor Johnson seems to speak so definitely. Professor Plowright, in his lecture before the Royal College of Surgeons, in February, 1891, held this rather different opinion. That it is at least uncertain "how the *Phytophthora* exists from the summer of one year to the summer of the next;" that those sexual organs which were found by Mr. Worthington, G. Smith, and thought by him to be the resting-spores of the fungus, have since been much disputed to be as such, and that "if we fall back upon the theory that the fungus hibernates in the tissues of the tuber, it seems to afford no satisfactory explanation of the process." It is also stated by eminent mycologists that the action of the mycelium upon the tissues of the Potato plant is essentially destructive, and when the tubers are affected with *Phytophthora* in the autumn months, they almost invariably pass into decay; but if infected tubers are preserved through the winter months, the mycelium dies. Also it is stated that the *Phytophthora infestans* and the wet-rot (*Bacillus amyloclavus*) cannot long live together; that the former is generally succeeded by the latter, and if very bad, destroys its mycelium. We know the life-histories of many of our most destructive parasitic fungi, such as rust and mildew, smut and bunt, ergot, &c., of Gramineæ, and how in each instance the life cycle is completed, and it would, I am sure, be very interesting to many of your readers if it could be explained how the fungus, whether through the mycelium, resting-spores, or otherwise, germinate in the spring "to spread disease in the newly-formed shoots," as Professor Johnson says it does. I have often planted diseased Potatoes in the spring, and found no difference whatever in the crop from those grown from healthy tubers; and similar results have often been recorded in the columns of your paper. *Alfred Girt, Shrewsbury.*

BRITISH GUANO.—I know of some soils which require little or no manure, and where the study must be not how much, but how little may be used. A safe method, however, is to have all the ground intended for the different crops trenched or double dug early in the autumn, and this will give the fowl manure a good chance of being well permeated through the soil during the winter. There is more in this early surface dressing than many amateurs are aware of. I stated recently in a small article, which you were kind enough to publish, that on my land, which is of a poor light sandy nature, that I top dressed six

square yards every morning, which proved sufficient for a heavy crop of Onions. Now on a good depth of soil of a rich loamy nature less than half this quantity is necessary. I strongly recommend all who have gardens and allotments to pay more attention to my plan of manuring and utilising the fowl manure. Some people residing not far from where I am scribbling these lines, are keeping over 200 fowls—half in a filthy condition, with tons of this valuable article under their perches, which has not been cleared out for 1, I dare say, some few years. Now, these very good, simple, and kindly-disposed individuals, will talk to you by the hour about this crop not doing well, and the other crop not paying, hard times, and such-like; and you may as well try to turn the "moon into a green cheese"—an old saying—as to convince them of their great mistake; they will turn you off with, or put you down with, such words as, "to err is human!" Well, I am now trying all in my power with object-lessons to prove to these good folks how they throw their money away foolishly. *Joseph Meredith, Rose Mount, Bishop's Cleeve, Eardisley, Staffs.*

THE HISTORICAL MULBERRY TREE AT SYON.—Visitors to the gardens at Syon House, Brentford, will note that this old tree, which bears a plate announcing that it was planted by an Earl of Northumberland in 1548, is renewing its youth in a very satisfactory manner. Some years ago a branch broke away from the old trunk while retaining its hold upon the stock; falling upon the ground, it began to put forth roots into the soil below it. Earth was brought and piled up above the rooting point, and now it has grown into a vigorous tree, thus handing down the old one to posterity in a rejuvenated condition. Every year it becomes an increasing object of interest, and bears testimony to its longevity. It was fully noted by Mr. Wytches, who has the satisfaction of seeing it flourish beyond his best expectations. *R. D.*

FLORIFEROUS EUCHARIS GRANDIFLORA.—Having read in the *Gardeners' Chronicle* instances of flowers of unusual growth or bloom, I should like to mention the fact that two pots of *Eucharis* are flowering for the fourth time this year. The bulbs are growing in 10-inch pots, and they stand very near to the hot water pipes in my stove-house. One plant has now sixteen spikes of bloom, and nearly all of them have five or six, and one has a spike of seven blooms, all fully open. *Robert Spilcaban, Birmingham.*

THE EUCHARIS MITE.—The enclosed *Eucharis* bulb, so badly affected with mite, has been lying in my office window since last June. It has been exposed to a very low temperature, the window having been frost-d over several times this winter. I quite believe that there is no cure for it save the one frequently given in the *Gardeners' Chronicle*, viz. the burning of all affected stock. *J. H. W.*

CEDRUS DEODARA.—The woods near to Belvoir Castle are noted for their fine timber trees of various kinds, but *Cedrus Deodara* cannot be counted a success; and even if it had thriven, I very much doubt if the timber would be of any value. *C. atlantica*, on the other hand, grows freely, and soon makes a fine tree, with a good straight bole, in which respect it differs much from the Cedar of Lebanon; nevertheless, I incline to the opinion that these two varieties are botanically identical. A fine specimen of *Cedrus atlantica* had to be cut down here after the storm at the beginning of 1894, and particulars of its size, &c., were noted in your columns soon after. The stem of this tree had a girth of 8 feet 6 inches at 3 feet from the surface, a good record for ninety-six years' growth; but I am informed that the timber proved very soft when it was sawn up a short time ago. There are many trees of it here of similar size which are growing in a strong blue clay that is reputed to be 60 feet in depth. These trees are sheltered to a great extent by older specimens of deciduous trees, and the height above sea level is 270 feet. *W. H. Myers, Belvoir Castle Gardens, Grantham.*

APPLEY TOWERS AND LADY HUTT GRAPES.—Although rather late on this subject, I will give my experience of these varieties, so few gardeners having given theirs. I planted some young Vines at the time these varieties were distributed, including one each of Appley Towers and Lady Hutt. The vine in which these Vines were planted had a very flat heavily-timbered roof, and was rather shaded, more

over the soil was not one of the best for the Vine. In order to obtain as much light as possible, the Vines are trained up the middle of each light, a brick path runs along the front, and prevents an outside border being made. The border inside the viney is divided into bins by brickwork partitions 3 inches thick, built in cement, extending from the front wall to the path, and each division contains two Vines, has the usual sort of drainage overlying a cemented floor, and soil to the depth of 2½ feet. These bins were made because owing to the narrowness of the border, it needed of renewing, and as the contents of one bin were renewed each year without disturbing the others, they had their advantages. The other varieties included in the same viney are Black Hamburgh, one of Madresfield Court, Buckland Sweetwater, and Foster's Seedling. The fruit is ripe by the beginning of August, and that of Lady Hutt is later than any of the others. Appley Towers is in my opinion the better Grape of the two. Both Vines grew vigorously. Appley Towers colours well, but its bunches as yet are not large; the berries resemble those of Madresfield Court, but they are not so large, and not so pointed as those of Black Alicante. The flavour when the bunches are allowed to remain on the Vines, as these did till November, is, I think, an improvement on Black Alicante; but the skin is not so thick nor so hard as in Lady Dowes' Seedling, than which variety it is an improvement as regards flavour. I am inclined to think it will prove to be a useful Grape, but less attractive as an exhibition variety. The best examples that I have noticed were growing on Vines in the gardens of Keele Hall in 1895, and perhaps Mr. Wallis will kindly give us his opinion of the fruit as grown in the good Grape soil of that place. The fruit of Lady Hutt does not please me, the greenish colour, also mentioned by others, being much against it, yet I have left it for a long time on the Vine well exposed to the light. The flavour, however, is better than would be expected, but it is not equal to Buckland Sweetwater or Foster's Seedling. It shows fruit free with me than Appley Towers, but this may be owing to fruiting too sparsely. It is a nice, round, good-size berry, which keeps well, although the skin is not very thick. *J. Lanbert, Paris Castle Gardens.*

HUYSHES' VICTORIA PEAR, ETC.—Respecting my remarks upon the above (see p. 11 in the issue for Jan. 2), I should have stated that the trees are growing in the vale of Berkshire, about fifteen miles from Reading, Oxford, and Newbury, either way. *J. C.*

A NEW TOLL AT COVENT GARDEN MARKET.—I should like to say a few words on a matter that is of great interest to a number of your readers, viz., the imposition of a new toll at Covent Garden Flower Market on the 1st inst. This new toll is one half penny per box on all cut blooms, &c., which arrive to be sold on commission, those stand holders who sell their own goods being exempted from payment of the toll. Now to me this seems strange—why should those who are non-stand holders be so taxed? Is it not such as we who pay the commission-agents' stand-fee? And, but for us, he would not require such stands. I really think that, considering the hard struggle we small folk have to live, the market-holders' tax would be content with the market-dues previously paid, an addition of a few hundred pounds per annum being of little account to him, although to us they mean a great loss. It seems hard that at the same time that our local rates should be reduced by the Government to help us, that all we gain by that, and more beside, should go into his Grace's pocket. It seems but a trifle; but, added to what we previously paid, it means a good deal. For instance, last week I sent eighteen boxes of blooms to the market, the cost of which amounted to 2s. 6d., and then of course, there is the carriage and salesman's commission. The tax is the little man's tax; the big grower has his own salesman, and is therefore exempt. *J. Coll.*

SOCIETY.

ROYAL HORTICULTURAL.

JANUARY 12. The first meeting of the committee for 1897 took place in the Drill Hall, James Street, Westminster, on Tuesday last. In the morning especially the weather was foggy, and there was but little sunlight. Despite these adverse external conditions, however, there was a very satisfactory exhibition, and, owing to several admirable collections of cyclamens, the display was a bright one.

[The term "accumulated temperature" indicates the aggregate amount...]

Table with columns for DISTRICTS, TEMPERATURE (Daily, Accumulated), RAINFALL, BRIGHT SUNS, and various weather metrics.

The districts indicated by number in the first column are the following:—

FRUIT.—AVERAGE WHOLESALE PRICES. s. d. s. d. Apples, Blenheim, per sieve ... 6 0-7 0

VEGETABLES.—AVERAGE WHOLESALE PRICES. s. d. s. d. Artichokes, Globe, per doz. ... 3 0-3 0

Trade has been slow the last week, but no alteration in prices. Wet weather against the sale.

SEEDS.

LONDON, Jan. 13.—Messrs. John Shaw & Sons, Seed Merchants, of Great Mairie Pond, Borough, London, S.E., write that there is now rather more inquiry for Clover and grass seeds.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending January 9, and for the corresponding period in 1896, together with the difference in the quotations.

Table with columns: Description, 1896, 1897, Difference. Wheat, Barley, Oats.

TRADE NOTICE.

We are informed that Mr. E. P. Brown, Seed Grower, Coggeshall, Essex, has admitted his two sons to partnership, and that the business will henceforth be carried on under the title of E. P. Brown & Sons.

NOTICES TO CORRESPONDENTS.

BOOKS: S. A. T. The Landscape Gardener, by J. Newton (published by Hardwick, Bogue & Co., Piccadilly, London); Parks and Gardens of Paris, by W. Robinson (Macmillan & Co., Bedford Street, Covent Garden); How to Lay Out a Garden, by W. Kemp (Braillor, Agnew & Co., Boulevard Street, E.C.); Landscape Gardening, by H. E. Milner (Simpkin, Marshall & Co., Stationers' Hall Court, E.C.); Gartenkunst und Garten-Sonn und Jetz, by H. Jager (Paul Parey, Berlin); C. B. Woodley & Co. Cyclopedia and How to Grow Them, by F. C. Edwards (published at 7, St. Bride's Place, London); Head Gardener, Dictionary of Horticulture. The work makes four handy volumes. The publisher is Mr. Upcott Gill, Bazaar Office, 170, Strand, W.C.

CHINESE SACRED LILY: China. The bulbs could not have been grown sufficiently long before importation, or the maturation was not complete.

ERRATUM.—In the article on Chrysanthemums (p. 32) of our last issue, Mr. Ollerhead desires us to state that he meant twenty-five plants were purchased, and not five, as there stated.

FIGS ON BACK WALL OF VINERY. I. I. E.—A bad piece for Fig trees, it being much shaded by the foliage of the Vines; and if the roots are not kept to a very narrow border, the result is strong, fruitless wood, which no sort of pruning or stopping will make fruitful.

INSECTS DEVOURING YOUNG FERN PLANTS: G. M. G. The grubs belong to one of the plant-eating two-winged flies (Diptera); it will scarcely be possible to say what species without breeding the insect.

LONDON COUNTY COUNCIL PARKS COMMITTEE: Constant Reader.—The official charged with the care of the public parks and open spaces is J. J. Sexby, Esq.; the names of the sub-committee dealing with them are unknown to us. Why not enquire at Spring Gardens?

NAMES OF FRUITS: T. W. S. Pears are too much bruised, from being over-ripe. No. 2 may be Glout Moreau.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—J. B. Lælia anceps Stella.—T. D. Lælia anceps alba has no purple colour on the lip. Yours, with six flowers on a spike, is a very fine example of L. anceps Sanderlanti, and very close to L. Dawson. The shrub is Lycopodium formosum.—R. C. Piley, Lælia albiloba.—V. anane creek, Market Street, 1, Dracæna terminalis, probably, but the foliage is so damaged by insects that identification is difficult; 2, Eucalyptus globulus; 3, Grevillea robusta; 4, Echeveria retusa.—M. V. 1, Polystichum acrostichoides; 2, P. angulare variety; 3, P. aculeatum; 4 and 5, arrived too much withered for identification; 6, Crocus imperati, probably.—E. M. Hypocoris radicata, probably.

SCHOOLS OF GARDENING: A. K. B. Taken in a wide sense, the following may be added to the list of educational establishments which you give: Trinity College Gardens, Dublin, Manchester, Sheffield, Cambridge, Oxford, Liverpool, Aberdeen (soon to be formed), Glasgow Botanic Gardens, Edinburgh. The Kent County School of Horticulture at Swanley Kent; the Duke of Bedford's experimental Fruit-garden at Ridgmont, Woburn; and the Gardens of the Royal Horticultural Society at Chiswick. We have not one purely gardening school fitted up with laboratory and scientific appliances similar to Geissenheim.

VINES IN POOR HEALTH: E. W. There is no trace of Phylloxera either in roots or shoots. All the fibres from the roots appear to have died, and the circumstances would indicate that the border is insufficiently drained, or may be it is composed of mould of too stiff or retentive a character.

WINTER ACONITE IN GRASS-LAND: J. T. We will send you a communication on this subject if you will kindly furnish full name and address.

COMMUNICATIONS RECEIVED.—O. V. von Siedl & Co., Udenna A.-W. S., C. W. B., W. B., Constant Reader.—W. H.—H. A. D., J. J., S. S., W. S., W. H.—J. B. H., B. H., B. H., B. H.—U. D., Berlin—W. E. G. J. R. L. J. L., Brussels.—E. G. C., J. H. V.—Professor Sargaut, Boston, U.S.—G. Green.—W. H.—F. E. R.—W. G. H. and A. P. (shortly).—E. C. C., Do B.—H. H.—R. W. M.—J. Bates.—H. W.—T. H., S. B.—W. THE

Gardeners' Chronicle.

SATURDAY, JANUARY 23, 1897.

THE PLANTS OF WEST AFRICA.*

A QUARTER of a century has now elapsed since Friedrich Welwitsch died. A new generation of botanists, with different aims and methods, has since arisen. In spite of this, to those who were privileged to know him his memory is still green. Nor is this surprising, for his was a unique personality. Stately in manner, prepossessing in appearance, full of knowledge in his own department, he was modest and retiring to a fault. To his friends the manner in which he endured poverty, cruel misrepresentation, and at length bodily suffering, was, though painful, by no means profitless as an example. The book before us contains an excellent portrait of the great botanist-traveller, and a sketch of his career, to which we must refer the reader for the full details. It must suffice here to say that, quitting Austria for Lisbon in 1839, he quickly set to work to explore the country in the vicinity. His botanical labours in Portugal continued until 1853. During the interval Welwitsch had the care at various times of the Botanic Gardens of Coimbra and Lisbon, and acted as garden-superintendent of the Duke of Palmella's gardens at Cintra, Alentejo, and elsewhere. He was one of the founders of the Horticultural Society of Lisbon, which was established in July, 1844. In 1853, Welwitsch started for Angola under the auspices of the Portuguese Government. Establishing himself in the first instance at Loanda, he speedily set to work to collect plants and other objects of natural history. Subsequently, he proceeded to the district of Golungo Alto, some 125 miles from the coast, where he spent two years, suffering greatly from fever, but never abandoning his work, and on one occasion enjoying the society of Livingstone for some weeks. From thence he proceeded to Pango Andongo, 250 miles in the interior, which he described as a botanical garden in the form of a park.

We cannot follow him in his subsequent wanderings, when he was often prostrated by fever. We can merely add that he subsequently went southward to Benguela and Mossamedes, where he found a mixed flora partaking of the characters of those of the Cape on the one side, and of Senegambia on the other. Further south, near Cape Negro, a desert region exists, and here he found that wonderful plant which bears his name (except, he it said, in this very volume!), and which created so much astonishment and excitement when its

peculiarities were first made known in these columns by Sir Joseph Hooker. Welwitsch's own sensations were "so overwhelming that he could do nothing but kneel down on the burning soil and gaze at it, half in fear lest a touch should prove it to be a figment of the imagination." No such botanical wonder has been since brought to light.

In 1861 Welwitsch returned to Lisbon, taking with him magnificent collections. We do not think his botanical collections have ever been surpassed in the care bestowed on their preparation, when due weight is attached to the climatal conditions under which they were made. Moreover, almost every specimen has a label attached to it containing numerous details as to the habit, uses, and distribution of the plants.

Finding that it was necessary to visit London for the purpose of naming and arranging his vast collections, he settled in the metropolis, and became entirely absorbed in this occupation. The Portuguese Government, however, ill-informed, as we must believe, of the real facts of the case, became dissatisfied, and ultimately suspended his salary. Welwitsch worked on as before, till his personal resources were well nigh exhausted; hopeless disease supervened, and on October 20, 1872, he was released by death.

To the ordinary reader, the details of Welwitsch's career, and the narrative of his extraordinary travels as given in this book, will appeal strongly. Professed naturalists will require that the labours of this much-tried man of science shall be turned to account. To some extent this has already been done, but in a detached and inconsequent form. Now we have before us the first part of a complete catalogue of the plants collected by Welwitsch. This has been prepared by Mr. W. P. Hiern, than whom no more careful, painstaking, or conscientious editor and compiler could have been found.

Some most interesting notes on the structure, and especially on the uses of plants, are given. We give an extract from one which appears on the very first page, and which from internal evidence is clearly attributable to Mr. Hiern. In other cases, it is not always clear whether it is the traveller's own notes which are copied or paraphrased, or whether the comments are from the pen of the editor.

"The Ranunculaceæ in the flora of Huilla, including the district of Bumbo, are represented by only three species of Clematis, and one species of Ranunculus, thus by four species altogether; nevertheless, they produce a striking effect upon the physiognomy of the forest landscape by the presence of immense masses of two erect species of Clematis, so that large tracts of pasture ground situate amidst the forests, during the flowering season of these plants, look at a distance as if covered with snow; and this effect is enhanced by the white-flowering Cephalaria centaurioides, Roem & Sch. (*Wlsw. Herb.*, No. 522), which grows in company with them; this happens in the months of February and March, when extensive tracts of land are flooded after the rains, which set in about October.

"On February 8, 1850, during an excursion towards the confluence of the streams Lopollo and Ferao, Welwitsch enjoyed ample opportunity to admire the scarcely imaginable magnificence of these species of Clematis; two species, each with whitish red flowers 2 to 2½ inches in diameter, and with stems 3 to 4 feet high, are erect, whilst a third species climbs high up the forest trees, and bears rather smaller white nodding flowers."

When the work is completed we shall, no doubt, learn the reasons why Mr. Hiern has

broken away from the usage of De Candolle's "*Lois*," the *Genera Plantarum*, and of the *Index Kewensis*. We have no doubt to Mr. Hiern's logical mind the changes he has made appear requisite and lawful, though we cannot but feel in this case that if really lawful "not all things are expedient." To attempt, for instance, to change the name *Camoensia* to *Gigantethnum* (see p. 285) seems to be to reduce the application of the law of priority to something very like absurdity. Had the name *Gigantethnum*, which it is proposed to substitute, been previously given by someone else, there would have been some reason for its adoption, but Welwitsch himself discarded the name he had originally given, but only in a preliminary and provisional publication, and himself, breaking the strict law which forbids an author from altering a name once given, adopted *Camoensia*. This is the name under which the plant is described in the *Genera Plantarum*, in the *Transactions of the Linnean Society* (where the plant is figured), in the *Flora of Tropical Africa*, and in the *Index Kewensis*, and till now we never heard or read of it under any other name.

If the matter were not so serious we should think the author was indulging in a practical joke when he abolishes the name *Cola*, and substitutes for the universally-known *Cola acuminata* the name *Edwardia lurida*, of Rafinesque! Where can the author have seen the type specimen of *Edwardia lurida*?

Another illustration of a similar character is the attempt to substitute *Calceolaria forficoides*, a Violaceæ genus. This proceeding is copied from Dr. Otto Kunze, but is one which cannot be adopted without great inconvenience. Moreover, it is one which implies that Dr. Kunze is in some way connected with the genus, when, unless we are mistaken, he had nothing to do with it beyond adding to the troubles of future students and monographers. Now, if there is one rule in the botanical code more reasonable than another, it is that which forbids us from attributing to an author something that he has not said. By extension this rule may well be applied to those who append their initials to species and varieties they have not investigated, but whose names they have thought fit to change.

The genus *Calceolaria* of Linneus is universally known; it has a place in the *Genera Plantarum*, and in the *Index Kewensis*, and is constantly used by gardeners who employ the name a hundred times where the botanist uses it only once.

It is surely in the interests of science to let such names remain, referring to their history in the synonymy. We do not doubt that the author can find justification for his practice, hence we cannot rightly call it frivolous. Nevertheless, many people will find it vexatious and uncalled for. Admitting the occasional necessity for changes of this kind, we plead, in the language of the old Biblical revisers, that the names "be retained as high as may be accordingly as they were vulgarly used." In any case, we imagine that *Camoensia*, *Welwitschia*, *Cola*, and certainly *Calceolaria* will remain vulgarly used in gardens for some time to come.

However tiresome these questions of nomenclature may be, they are more matters of arbitrary arrangement; but in spite of congresses, laws, and codes, and even examples such as we have mentioned, botanists cannot or will not agree, to follow the rules laid down. In themselves names have no scientific importance, beyond affording a mark for purposes of

* *Catalogue of the African Plants collected by Dr. Friedrich Welwitsch in 1834-1853*, Part I. By W. P. Hiern, M.A., F.L.S. London: printed by order of the Trustees, British Museum (Natural History), Cromwell Road, S.W., 1896.

identification, and hence they need not be subjected to treatment which would be essential in matters of science. They fall into insignificance, for instance, in comparison with the subject-matter of this book. In the present case this is so important, the notes so interesting and so valuable for morphological and economic reasons, that botanists must perform feel themselves under such great obligations to Mr. Hiern and the trustees of the British Museum, that they will condone these vagaries of nomenclature. The present volume extends only to the Rhizophoraceae, so that it does not cover more ground than the volumes of the *Flora of Tropical Africa* already published. It has an index of genera, in which the synonyms are given in italics so as to offer some compensation for the changes in nomenclature to which we have alluded, and doubtless, further concessions of this kind will be given at the close.

NEW OR NOTEWORTHY PLANTS.

SELENIPEDIUM BOISSERIANUM, Rehb. f.

The *descriptio princeps* of the above species was published in the *Xenia Orchidibus*, 1853, p. 176, t. 62, although the name had already appeared in *Banplantha* in 1854, p. 118, without any description, as related to *Selenipedium* Hirtwegii.

Reichenbach, *l.c.*, says:—"We know of only one specimen of Pavon with the label *Cypripedium grandiflorum*, Pillao, 1787. The name *grandiflorum* seems not to be desirable, for there are other *Selenipediums* with larger, or equally large, flowers. We believe, therefore, that the manuscript name must altogether be laid aside, especially as the plant is no true *Cypripedium*; and it gives us much pleasure to dedicate this beautiful plant, probably unique in the collections of Europe, to its proprietor, M. Edmund Boissier, to whom we are under so great obligations."

Unfortunately, that unique specimen was never returned by Reichenbach to its proprietor. It lies buried with the rest of his Orchids for twenty-five years, along with other uniques which had been entrusted to him.

Selenipedium Boissierianum (see figs. 14, 15) is to be found in Peru, and we grow it next to *Selenipedium curvifolium*. We have not found it easy to cultivate, and it is only the second time that it has flowered with us; others may have been more successful, although we do not see it often quoted in catalogues. The photographs were taken by Master Frédéric Barbey, Chaubúzy, Switzerland, in December, 1896, *William Barbey*.

MICHANMA TCHIHATCHEFFI.

Seeds of this fine Campanulaceous species have been collected by Mr. Siehe in the Ciscaian Taurus, and brought into commerce by Mr. F. C. Schmidt at Erfurt. It is a biennial, which forms in the first year a large rosette of 2 feet in diameter, from which springs in the second year a large flower stalk 6 to 7 feet high, branching at the base, and bearing a large quantity of flowers similar to those of *Platycodon Mariasi*. I have seen a large photograph of the plant, which Mr. Siehe made in the original locality, and I must say I know few plants of a like majestic habit. It is certainly one of the best importations of biennials of the last ten years. *U. B.*

CATASETUM SEMIROSEUM, G. Beck.

This plant, belonging to the group *Catasetum splendens*, is an importation of Linden's, and flowered in Prinz Liechtenstein's garden, Esgrub, Moravia, in 1895. Mr. Lauche, the garden director at that place, sent flowers to the editors of the *Wiener illustrirte Garten Zeitung* for determination, the species being unknown to him, and they have given it the above name. *Catasetum semiroseum* has the following characteristics: petals all sepals whitish or light red, towards the base richly spotted with red, and tinged with red to the apex. The lip is in colour of

a somewhat greenish-white, whiter towards the edge, and towards the base of a wine-red, or almost carmine colour; the spur is, however, yellow, with red spots. The column is white, except at the base, which is coloured purple.

Amongst *Catasetum* figure 1 and described in *Lindenia* is none which quite resembles *C. semiroseum*. *C. mirabile* (*Lindenia*, t. COLVIII.), which is the nearest approach to it, and which may probably be recognised as a form of it, is deep yellow in colour towards the base, but not in the spur; it tinged with red-brown, not furnished as in *C. semiroseum* with a white and red lip, and greenish petals and sepals, and but little tinged, but resembling *C. semiroseum* in the purple-coloured base of the column.

violet-coloured sepals, and a greenish unspotted lip, as well as a white column. Other forms of *C. splendens*, as *C. Lindeni* (*Lindenia*, t. COLVII.), have more yellow colour in the flowers, and a yellow-tinted lip.

Catasetum semiroseum appears therefore, according to our opinion, to be an interesting new, and hitherto undescribed form of *C. splendens*, which deserves especial admiration by reason of its pretty colouring. *Dr. G. V. Beck.*

THE DEODAR AS A FOREST TREE.

I CANNOT say I am greatly impressed by the testimony brought against this tree by your correspondents. I asked for information as to its merits

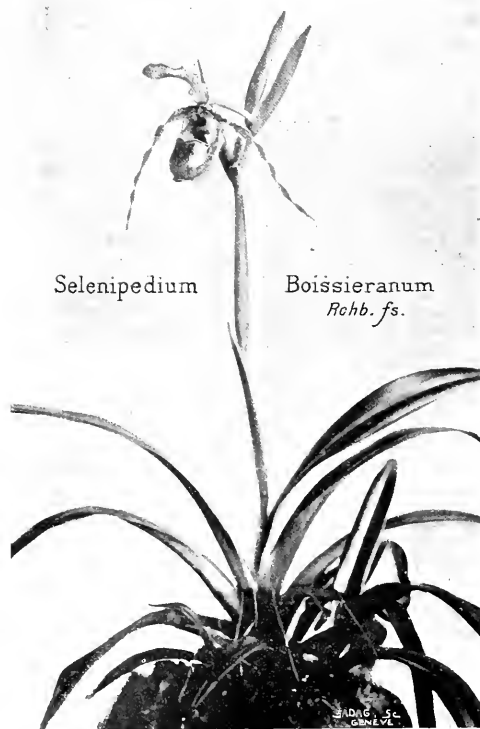

FIG. 13.—PLANT AND FLOWER OF SELENIPEDIUM BOISSERIANUM.

This last feature is not observable in any of the magnificent examples of forms figured in *Lindenia*, t. DII, DIII, notwithstanding the fact that amongst these are found several which, in the colouring of the petals and sepals, come very near to our plant.

Among similar *Catasetums*, *C. splendens* var. *Alicie* (*Lindenia*, t. COLVIII.) exhibits towards the apex (but not at the base) darker purple coloured sepals and petals, a pure white lip, with a yellow-coloured expansion of the spur and a white column; and in these flowers figured in t. DII, to the left-hand beneath the figure of *C. splendens*, the spotting of the perianth is missing. *C. splendens* var. *rubrum* has a yellow-coloured lip; *C. Luciani*, Cogn. (*Lindenia*, t. COLIV.), possesses petals that are less spotted, dark

as a timber-tree under sylvicultural or plantation treatment. Your correspondents indulge in surmises, but do not seem to have the trees. Mr. Divers' letter is an example. I know the kinds of trees that thrive at Belvoir, and it must be one of the few places where its botanically identical relations—*Cedrus atlantica* and *Litani* do so well, and the Deodar is a failure—for, as a rule, where these two grow, the other will, and does thrive. Sir C. Strickland, in your pages, and elsewhere, says I do not seem to get much support. Well! there are our own trees, on one of the bleakest aspects in Yorkshire, and they will take a good deal of arguing away. Then, there is Veitch's *Manual of the Coniferae*, where the species are carefully described,

which supports me thoroughly. Next, there is *Johannes Scullin's Pinaceae*, even more favourable in the same direction. Next, Grigor's *Arboriculture*, which says ditto, and describes fine examples forty-five years of age, not far from John o' Groat's, and at other places in the Highlands; and lastly, there is Brown's *Forests* on the same side. Experienced cultivators and writers may be credited, to some extent, with knowing something of their subject. Can Sir Charles match them on the other side? As to Mr. A. D. Webster's assertion that the Deodar is

but for comparison I herewith send you good, mature, thick pieces of old limbs of the Deodar, the Cedar of Lebanon, and the Larch—from trees growing almost side by side and under equal conditions. The Deodar limb is about forty years of age, Cedar of Lebanon a little older, and the Larch older still. I have cut them and planed them to show the wood sectionally and lengthwise, and you will notice that in the Larch and Deodar the heart-wood appears to be formed earlier, and is much more clearly defined, than in the Cedar of Lebanon—which

Deodar I cannot help giving the following further quotation, corroborating, as it does, my opinion of its sylvicultural merits:—

"In these forests, as elsewhere, Deodar is pre-eminently a shade enduring tree, especially during the first half-century of its life. Seedlings will remain alive under the densest cover for years.

"The preceding figures prove clearly that young Deodar can not only survive for many years under a dense leaf-canopy, but that a dense leaf-canopy is less harmful to it than complete exposure to weather influences, the most destructive of which are evidently drought, strong heat, and the weight of superincumbent snow, which breaks the leading shoot and bends down and distorts the thin flexible stem. Thousands of vigorous saplings and poles attest the fact that, provided the cover surrounding and overhead is not extremely dense, young Deodar is always able, with its long, slender, graceful leading shoot, to pierce through the over-topping leaf-canopy into the direct sunlight above without suffering any very appreciable diminution of vigour. Hence thinnings made with the object of giving more light and growing room to Deodar must be made cautiously and with a sparing hand. No greater mistake could be made than to thin out the forest surrounding or overhead in any wholesale manner."

In conclusion, I should imagine that there are plenty of thriving examples of the Deodar throughout the country if we could hear of them. What became of the ton of seed sent from India by the Government between 1850 and 1860? The late Mr. McNab, Curator of the Edinburgh Botanic, stated, in 1867, that this seed was distributed among three nurserymen, viz., Messrs. Gleadinning, of Chiswick Nursery, London; Messrs. Skirving, Walton Nursery, Liverpool; and Messrs. Lawson & Son, Edinburgh; and that the quantity raised in Edinburgh was very large in proportion to that raised elsewhere, because the seed was, for the first time in Europe, sown broadcast, like Scotch Fir, in the open air, instead of in pits or frames, as in London and Liverpool (*The Gardener*, January, 1867). Mr. McNab speaks of many of the earlier-planted trees he knew of as being in a "faultless state," but says the unprecedented winter of 1860-61 injured many Deodars, chiefly those planted in damp situations, and those trees suffered worst which had their branches broken and disrupted by the frost, while other Deodars growing side by side suffered no injury whatever. In any case, I am very dubious about one cold spot here, where also every leaf of every tree is coated with soot from the surrounding coal and iron-works, being an exceptionally favourable spot for the Deodar, and we have a good few up and down of all sizes in all sorts of situations, and have not lost one; while the trees that have grown fastest are in a mixed Fir plantation, where they beat the Cedar of Lebanon, the Spruce, and keep pace with the Scots Fir and other species. I would have thought also that the Deodar would have succeeded at Sir Charles Strickland's fine place, near Bridlington, which I had once the pleasure of being shown over, and where I saw many fine trees, including, if I remember rightly, the Deodar. I remember my visit very well, for there I saw, for the first time the rather rare *Sirex gigas*, a destructive Pine-borer; and a young plantation of Larch artificially pruned of their lower branches, and wondered what was the object of it. *J. Simpson, Wortley, January 15.*

Selenipedium Boissierianum
Rehb. fs.

FIG. 14.—FLOWER OF SELENIPEDIUM BOISSIERIANUM. (SEE P. 54.)

not well adapted to exposed sites, the correspondence in your pages goes at least to show that exposed sites are the only sites that do suit the tree. In a very lengthy and particular report of the Deodar, copied into *Woods and Forests* from *The Indian Forester* in 1884, it is stated that in its native haunts the Deodar "avoids southerly slopes, but thrives on every other exposure, being perhaps most vigorous and abundant on slopes facing the north-east."

The same report states that the Deodar "avoids the bottoms of ravines and valleys and similar damp places," a fact fully corroborated in *The Field*, in regard to this country. The timber of our Deodars is neither soft nor inferior. I cannot send you a tree,

means earlier maturity. The Deodar I have marked by a "D" on the bark, the Cedar of Lebanon by an "L," and the Larch is not marked at all. The examples sent are not seasoned, and were all cut off the tree two days ago. "Hard and heavy" is the Admiralty test of timber, and I think the Deodar is about the best example of the tree I very heavily. E.P.]. I think little of any wood taking a fine polish as a test. The Larch, by common consent, is a coarse wood in the grain, but it will polish like a looking-glass. I have a book-case made from a Larch tree (grown at Drumlanig) forty years ago as glossy as well-varnished mahogany to this day, and neither warped nor shrunk. From the *Indian Forester* report on the

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUMS AT WALTON GRANGE.

For many years W. Thompson, Esq., J.P., of Walton Grange, Stone, Staffordshire, has been known to possess one of the finest collections of Odontoglossums in the country; and so well are their requirements understood by Mr. Thompson and Mr. Stevens, his gardener, that it would be almost impossible to pay a visit to Walton Grange and not find plants in flower that would gratify the most

passionate orchidophile. At the present season of the year no one would expect to find a large number in full bloom in any one collection; therefore, the relatively fine display at Walton Grange is calculated to occasion surprise. Amongst the many *Ontoglossum crispum* in flower, there was none that did not possess beauty of form, much substance, or distinctive markings. Of named varieties, there were *O. c. fastuosum*, the original plant named by Reichenbach, showing the distinctive small-sized, regular, bright purplish-blown spots; *O. elegantius*, conspicuous for its pale yellow ground colour, and chocolate-brown markings; *O. Andersonianum*, represented by several forms, each differing more or less; *O. malraense*, a species not often observed growing robustly, was carrying five fine large blooms which had plenty of substance; *O. Pescatorei*, a single plant, carrying four large branching spikes, and one hundred flowers. Plants of *O. tripidiana*, *O. patchellum majus*, *O. vesillarium* were remarked in full bloom. The following species and varieties were well represented, viz., *Oncidium Forbesii*, *O. tigrinum*, *O. crispum*, *O. undulatum*, *O. ornatiorhynchum*, and its beautiful and fragrant variety, *O. o. album*. The darkest form of *Lelia* accepts that I have yet seen is found in this collection—a beautiful specimen carrying six large flower-spikes. I also observed an especially fine specimen of *L. Gouliana*, with seven flower-spikes—the variety one of the best in cultivation; also the useful *L. autumnalis-arubrensis*, DeKoningh, a portion of the plant figured in the *Orchid Album* was in bloom, side by side with the variety *L.*, or *Lelio-Catleya Arnoldiana*, obtained by crossing *L. purpurata* and *C. hiberna*. *Cypripediums* are but new favourites with Mr. Thompson, and as yet the collection of them is not a large one, although those he already possesses are of the choicest varieties. The following are some of those in flower at the time of my visit:—*C. Leeanum*, *C. L. giganteum*, *C. L. superbum*, *C. Calypso*, *C. Lathamianum*, *C. Swintonnel*, *C. insigne* Dorothy, and *C. Minosa*, a new *Veitchiana* hybrid, of which more will yet be heard. Of *Catleyas* and *Laelias*, *Vandas*, *Zygopetalums*, *Masdevalias*, and *Angreums*, there was an exceptionally good display of bloom for the season. *J. I.*

A CASE OF ABNORMAL FLOWERING IN DENDROBIUM NOBILE.

I have a plant of *Dendrobium nobile* Wallichii now in flower which has the peculiarity of flowering two years in succession from seven of the nodes; five are on one and two on another of the old pseudo-bulbs. In all there are sixteen flowers, which are quite as large, and the colouring as good, as those on the young pseudo-bulbs. During my experience I have never noticed such an occurrence before, although some of your numerous readers may have done so. In my opinion the variety *D. n. Wallichii* is far superior to the ordinary *D. nobile*, as the growths or pseudo-bulbs are longer and stouter; the substance and colouring of the flowers are much better, and the nodes are not so liable to turn to growths instead of flowering, on a plant being placed in a brisk heat, as is the type. I grow both side by side in the same house, the plants thus receiving similar treatment. *W. Silecock, Hollycombe Gardens, Liphook.*

THE ROSARY.

THE PARENTAGE OF ROSES.

Up till a comparatively recent period this was a subject which from Rose-cultivators received inadequate attention. Among those who were somewhat exceptional in their estimate of its importance, and perceived intuitively that the origin of a Rose had much to do in the way of determining its capabilities, was the late Henry Bennet, one of the greatest of modern raisers, many of whose creations, such as Grace Darling, Viscountess Folkestone, Captain Hayward, Mrs. John Laing, Princess Beatrice, Cleopatra, and Princess of Wales, quite rival those of the late M. Guillot. All of these have

almost ideal characteristics; they are vigorous in habit, distinctive in colour, exquisite in form, attractive in fragrance, and very floriferous. And there can be no question that attributes such as those which distinguish these varieties were largely the result of cross-fertilisation.

The good work in this direction begun by the late Henry Bennet has been carried on effectively by Mr. William Paul, Mr. George Paul, and the Messrs. Dickson of Newtownards; and hence we have at present, in all probabilities, finer varieties of the Rose, and harder in constitution than in any previous period, however eminent for productiveness, in the history of horticulture.

Our knowledge of the derivation of modern Roses is necessarily fragmentary, but perhaps all the more interesting by reason of the limitations by which it is environed. Among the oldest of their august parents is the venerable *La Reine*, whose name I greatly fear is in great danger of being forgotten, but which may still be found perhaps in the late Mr. Rivers' *Rose Amateur's Guide*, a work lovingly written, and universally revered. It is not discoverable in modern catalogues, for the obvious reason that like many of its contemporaries, it has long been superseded, and therefore consigned to oblivion. From it Levet derived in 1871, François Michelin, a most commanding Rose; and two years earlier, that grand autumnal bloomer, Paul Neyron. General Jacquemont, raised as far back as 1853, has proved itself a most prolific parent; and its descendants, such as Pierre Nottig, Xavier Olibo, Sémateur Vaisse, Charles Lefebvre (so greatly embellished by the Dean of Rochester, who affirms that its first appearance marked an epoch in the history of the Rose), Alfred Colomb, and the incomparable Duke of Edinburgh, varieties not yet entirely superseded by any of their successors, have been for the most part, I might almost say inevitably, in virtue of their origin, of brilliant complexion. Jules Margottin has also been productive; to it we owe the still highly popular Beauty of Waltham, raised by Mr. William Paul in 1862, valuable alike as a garden and exhibition Rose; Duchesse de Vallombrosa, Magna Charta, and Thérèse Levet; the last-mentioned variety being the parent of that beautiful Scottish hybrid perpetual entitled Duke of Fife, "obtained" (I believe that is the correct term) by the Messrs. Cocker of Aberdeen, who have also given us two of the sweetest of all modern introductions, Duchesse of York and Duchesse of Fife, of which the latter was derived from Countess of Rosebery.

From Sémateur Vaisse have come Madame Victor Verdier and other bright varieties of kindred character; while Charles Lefebvre, raised by that consummate French rosarian, M. Lacharme (who was also an eminent wine-originator) in 1861, has given us Dr. Andry, of lustrous carmine hue; Horace Vernet, a splendid crimson of velvety texture, but, very unfortunately, of most limited capability in the direction of growth; Lord Macaulay, a Rose of great substance and brilliancy, introduced into cultivation in 1863, a contemporary of Marie Banmann and Duchesse de Moray; and Mrs. Harry Turner, a much more recent production, of exceptionally beautiful colour, its crimson hues flashing through deep maroon like the glory of sunset through a purple cloud.

I should ere this have mentioned that among the finest dark descendants of General Jacquemont are Prince Arthur and Duke of Albany, the former raised by Mr. Benjamin R. Cant of Colchester in 1875, the latter in 1883 by Mr. William Paul. These are among the grandest Roses in my garden. I find them much more vigorous than Horace Vernet, and infinitely more reliable than such varieties as Abel Carrière and Prince Camille de Rohan, which, if grown in a strong sun, are certain to be "burned;" while, if relegated to a shadier region, their flowers, for lack of inspiration from the heavens, fail to appear. A. K. Williams, a Rose of less capricious character, of perfect form, and satin-crimson hue, is generally supposed to have been derived from Alfred Colomb. Duke of Edinburgh is the still-surviving parent of a most fascinating family, including Brightness of Chesham, the eminently exacting Reynolds Hole,

whose virtues and vices are exactly those of Pierre Nottig and Prince Camille de Rohan; the luminous Duke of Teck, and the beautiful maroon-shaded Sultan of Zanzibar. No cultivator who compares that darkest of crimson Roses, Sir Rowland Hill, with Charles Lefebvre, could fail to find the affinities existing between these. Yet here again, the law of variation has found room to intervene. It is also discoverable in *Caroline Testout* and *Augustine Guinoisean*, both of which are interesting variations from the fragrant *La France*. It is not quite so observable in *Duchesse of Albany*, unless in the stronger growing habit of that variety, and its somewhat darker hue. Of *La France* itself the origin was not known, even to M. Guillot, by whom it was discovered among his successful seedlings in 1867—a memorable year in the history of the Rose.

Catherine Mermet has been rivalled, if not eclipsed, by several of her daughters, such as *Bridesmaid*, the *Bride*, and *Muriel Grahame*, all of which possess distinctive endowments, and the "fruity" fragrance of their eminent parent. *White Lady* is an artistic advance on *Lady Mary Fitzwilliam*, a majestic Rose, from which came also *Margaret Dickson*, one of the most notably endowed of the white hybrid perpetuals, whose colour, however, has been derived from *Merveille de Lyon*. The great Irish Rose (*Margaret Dickson*) is an inveterate grower, and has a tendency to expend its strength in the production of superfluous wood; this, and an occasional lack of compactness in the centre, are its only limitations, for which its remarkable beauty, its combined strength and sweetness, make ample amends. By reason of its purer colour and greater productiveness, it is much more valuable than *Marchioness of Londonderry* for garden decoration. *David R. Williamson.*

FERN VARIETIES.

REFERRING to the interesting series of articles on "Methods of Plant Propagation" which are now appearing in your columns, I note that the writer, "Experience," follows up a very clear and accurate description of the *modus operandi* of Fern propagation through the spore by a theory of variation which I cannot help contesting. "Experience" writes, "I have little hesitation in saying that all the singular and interesting varieties in the *Lady Fern* (*Athyrium*), in the *Button-hole Fern* (*Scopolopodium*), with which the late lamented Mr. Sim, of Foot's Cray, made such a long catalogue of, resulted from cross-fertilisation during the complicated germination of the spore." Passing by the fact that a reference to Mr. Sim's Fern Catalogue, which lies before me as I write, and is dated 1863, is scarcely up to date, considering the wonderful development of British Ferns in the subsequent thirty-three years, I would call attention to the fact that of the fifty-seven varieties described by Mr. Sim therein (many of which would not now be grown, being imperfect seedling forms), all the typical good varieties were found wild in various parts of the country; while in Mr. E. J. Lowe's recent list (1891), out of 313 varieties of this species described, no fewer than ninety-six are wild finds, and the great majority of the rest are sub-varieties raised therefrom, only a few being recognisable as crosses. With regard to the *Hart-tongue* or *Button-hole Fern* (a new name to me, but very appropriate as descriptive of the appearance of the long spore heads), the type forms are again all wild finds, although Mr. Lowe has succeeded in raising an immense number of combined varieties. In his list of varieties of this species, no fewer than 218 were found wild. The simple fact, however, that these sports originate so freely in a wild state does not of itself confute "Experience's" theory; it must be considered, in conjunction with the other facts, that these wild sports are almost invariably "solitary" finds so far as their individual peculiarity is concerned, and that there is absolutely no evidence to show that the more cross-fertilisation of two normal forms induces a change of type. In wet weather it is highly probable that among closely-crowded prothalli cross-fertilisation is frequent, and

doubtless the atherozoids of one prothallus are often carried to another by insect agency, so that if this caused sporting, varietal finds should be frequent enough. As it is, however, though a large number are now in culture, the wild, i.e., new finds, are but slowly accumulated, and it needs a very keen hunter, a vast stock of patience, and a lifetime to boot to form a collection worthy of the name on one's own account by simple search. On the other hand, when once a "break" from the normal is found, it is usually possible, starting from this, to "improve" it or increase its peculiarities by selective culture from spores; but here again there is no evidence to show that the subsequent diversity of the seedlings is due to cross-fertilisation, except where different varieties are purposely sown together in order to obtain combined types. At one of the Fern conferences some years ago, I exhibited a number of *Athyria* raised from unpaired spores, which in their diversity rivalled even Mr. E. J. Lowe's extraordinary crosses, though they all sprang from one plant and one sowing. What cause the initial variation in an original sport is a profound puzzle, and a marvel to boot, when we find

sources of biological phenomena, from which doubtless, sooner or later, a fuller comprehension of the underlying laws of variation will result. *Chas. T. Drury, F.L.S.*

WINTER-FLOWERING PLANTS AT ARUNDEL CASTLE GARDENS.

The demand for flowering plants and those with ornamental foliage is great at Arundel Castle all the year round. Especially called for are flowers for embellishing the church at festive seasons. At the present time there is a grand display of *Calanthes* in one of the houses, which is a notable example of good cultivation. Some of the plants of *C. Veitchii* have as many as forty expanded flowers on some of the spikes, and so great is the vigour of some of the bulbs that four spikes are produced. Some were observed in which the flower-spikes emerged from the extreme top of the pseudo-bulb. *C. vestita rubra* and *C. v. lutea* are also grown in great numbers, and do equally well. On the occasion of a recent visit 500 spikes of these three varie-

CULTURAL MEMORANDA.

FRUIT-GROWING IN LONDON SUBURBS.

FRUITS of various kinds can be grown successfully in the suburbs of London, which at times are enveloped in fog. Mention was made in a recent issue of the *Gardeners' Chronicle* of Vines at Tewkesbury Lodge, Forest Hill, which I may say I had the pleasure of seeing about eighteen months ago, and which struck me as being thoroughly well done. The viney is a very fine house or houses. I was also struck with the wide distance apart at which the Vines are planted, which, no doubt, is a great aid to successful Grape culture. I may be wrong, but should say that the Vines had a space of 6 to 7 feet between them. But there are other places equally near town where fruit-growing is carried on with marked success, namely, at Gunnersbury Park and House; also Mr. Tate's, at Streatham, and at places where the gardener is not allowed to exhibit. At one place in particular, Hazlewood, Upper Norwood, Mr. Munday, the late gardener, produced very fine Grapes, and thirty years ago, when I was there as under gardener, Peaches and Nectarines, finer in size, shape, colour, and flavour could not be found elsewhere. *W. Ravenhill.*

A METHOD OF CULTIVATING EUPHORBIA PULCHERRIMA.

Many of my friends have asked me to put in print my methods of cultivating *Euphorbia* (*Poinsettia*) *pulcherrima*. I take the cuttings in August, and put them singly into 3-inch pots in a propagating frame, and as soon as the pots are filled with roots they are potted into 5 inch pots. The compost I make use of consists of turfy loam, peat, silver-sand, charcoal broken up small, and a small quantity of bone-meal. I keep the cuttings near the glass in the stove for a week or two after potting them, then set them in a cold-frame, affording plenty of air by day, shading them for a time from bright sunshine, keeping them on the dry side for a time, and never afford stimulating food till the bracts begin to show. The plants are removed to a house with a minimum degree of warmth of 60° about the beginning of October, and fed with Thomson's manure; and I had plants at Christmas with bracts that measured 17 inches across. The secret of success in growing this plant is to get the wood thoroughly matured. *Alexander Hay, Ashford Gardens, Wiltshire.*

TREES AND SHRUBS.

PICEA OBOVATA.

THIS species is by no means commonly cultivated, the climate of our country, save in a few unusual situations, seeming unsuitable to its requirements. It is hardly enough, coming from Siberia, yet it has generally a miserable and starved appearance, which is probably owing to our mild and humid climate. I have seen a good specimen growing in an open, airy, though sheltered position, on high-lying ground; but, indeed, neither in an ornamental nor useful capacity is the tree worthy of culture. It is somewhat after the style of the common Spruce, but altogether lighter and with litho branches, and drooping branchlets. Cones are freely produced, these being sub-erect, and just half the length of those of the common Spruce, or about 3 inches. They are nearly egg-shaped, or obovate, the scales' edges being quite smooth, as opposed to those of the common Spruce which are crenulated or wavy. Unless for planting as a botanical specimen in the pinetum, I would not suggest that *Picea obovata* be procured.

PINUS LAMICO PALLASIANA.

THIS is a far more distinct and valuable forest tree than is generally supposed, although in the latter respect it cannot compare with the species in the production of straight clean timber, as it branches more freely, and these are proportionately heavier and larger, and produced down almost to the ground-level, on trees growing in the open—a rare occurrence with

FIG. 15.—GROUP OF CALANTHES AT ARUNDEL CASTLE.

an entirely new plan introduced on more symmetrical beautiful lines, combined with such stability and constancy that the spores produce the new type exactly for generation after generation. That cross-fertilisation does this is out of the question; myriads of flowers are so constructed that cross-fertilisation is ensured, and it seems to be a beneficial factor throughout. This, however, tends to preserve the type by levelling down individual peculiarities rather than to lead to the wide and sudden departures to which your correspondent refers. As regards systematic hybridisation, that has long since passed the "endeavour" stage, the possibility of crossing allied genera being demonstrated by Mr. E. J. Lowe's combination of *Ceterach officinarum* and *Scolopendrium vulgare*, a note upon which appeared in your columns some time back; while Mr. Schneider's successes with *Polypodium vulgare* and several widely different exotic species, P. Schneideri to wit among them, place the practicability of union between allied species beyond all doubt. Of late years, indeed, a very considerable addition has been made in this direction to our knowledge of Fern life, and since the attention of scientific botanists has been brought to bear on the varietal forms, they have been found to constitute a rich

ties combined were to be seen in one house, arranged on a groundwork of Ferns, forming a very fine sight (see fig. 15). Other species of Orchids are cultivated, viz., *Cattleya*, *Dendrobium*, *Cypripedium*, and *Oncotoglossums* of different species; the charming *Masdevallia tovarense* in well-flowered examples; grand specimen of *Cymbidium eburneum* which was throwing up dozens of flower-spikes; *C. Lowianum* about to expand its flowers—a well-grown specimen, with several fine flower-spikes. *Euphorbia* (*Poinsettia*) *pulcherrima*, and other *Euphorbias*, are extensively grown; many of the former had fine bracts, which measured 18 inches across. Among other plants observed in quantity were *Primulas*, zonal *Pelargoniums*, late varieties of *Chrysanthemums*, *Cinerarias*, *Cyclamens* *vulgaris*, *Butterfly*, *Salmon Queen*, &c. *Lily of the Valley* is extensively forced, and single crowns are those principally used. *Begonias* *Gloires de Secaux* and other varieties for winter bloom receive much attention. Several houses are filled with *Palms*, *Coliciums* (*Crotons*), *Draecenas* in well grown examples. I also remarked some grand *Richardias* carrying many spathes. The various departments are well managed by Mr. Burberry, the Duke of Norfolk's head gardener. *A. O.*

the species. I measured a short time ago one of the largest specimens of *P. L. Pallasiana* growing in this country, which was fully 75 feet in height, the spread of branches nearly as great, with a stem girth at 3 feet of fully 9 feet. The tree is growing on light sandy loam in a Surrey park, and it is certainly a very handsome specimen, the long, sweeping branches, much-divided trunk, and deep green bristling foliage rendering it peculiarly distinct and ornamental.

The cone production of *P. L. Pallasiana* is remarkable, at least when compared with the species, nearly every branchlet tip bearing a trio. The cones are much bigger than those of *P. Lario* proper, being from 3 to 4 inches long by 1½ to 2 inches at widest part, and of a pleasant yellow-ochre colour. Even the lower branches bore cones freely, a by-no-means common occurrence with any member of the *Pinus* family.

But the reason that I wish particularly to bring this variety under notice is for its now justly acknowledged value for planting in peaty soils that are not over-dry or well drained. A curious example of this was brought up in my notice recently, where a Larch plantation formed on peat bog turned out a failure owing to drainage having not received sufficient attention. The ground certainly had been drained after a fashion, but too few water-channels had been cut, and the consequence was that, owing to excessive dampness, all the trees, excepting such as had been planted by the ditch-sides, became covered with a lichen, and gradually would have died out had they not been removed. A number of fresh drains were cut, the original ones cleared out and deepened, the Heath, Bilberry, and other shrubby growth cleared away, and the ground replanted with the common Scots Pine and the present variety, *P. Lario* *Pallasiana*. These trees are now models of beauty and health, the foliage being of the brightest and healthiest description, and the rate of growth rapid—all pointing out that they are peculiarly suitable for peaty soil and a fully exposed situation. *A. D. Webster.*

COLONIAL NOTES.

A NEW YELLOW-SPATHED RICHARDIA.

I enclose a photograph of two plants of a new golden *Richardia*, grown and flowered by me at my residence, Rhine Villa, Sea Point. You will notice the bold, vigorous habit, and bright variegation of the foliage. This, combined with the large, deep, golden blooms freely produced, make a plant difficult to surpass in effectiveness. The plants come from a different locality to that in which *Richardia Elliottiana* and *Pentlandi* were discovered, and they are in every respect an improvement upon them. I flowered them for the first time last season, the two pots producing sixteen spathes. The same plants now in flower, carry nineteen blooms, one of which has a "double" spathe. The colour is of the brightest shade of yellow, and the spathes are very large. *Donald Ross, 50, Bree Street, Cape Town, South Africa.* [The photograph sent, exhibits two stocky plants with broad leaves set on rather short petioles, regularly spotted over the entire surface of the blade. Spathes as high or higher than the leaves. Ed.]

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

The Propagation of Gooseberries and Currants.—Cuttings of approved varieties should be taken off at once. They should be made about 12 inches long and consist of the butt ends of straight shoots. Remove all the buds except four at the top, to obtain bushes with 5 or 6 inches of clear stem above ground. The cuttings should be inserted 6 inches apart, in rows 12 inches asunder, and a border under a north or east wall will be a suitable place for them, but they will root equally well in the open. The ground having been dug, put the line

down, and stick the cuttings about 3 inches in the ground at the distances indicated, and tread the soil on either side in doing so.

Varieties of Gooseberries.—White; Cheshire Lass, Whitcomb, and Bright Yellow; (Yellow), Golden Drop, Early Sulphur, Yellow Champagne; (Green), Berry's Early Kent, Green Gascogne, Green Hedgehog, Rosebery; (Red), Whinham's Industry, Crown Bob, Rifeiman, Lancashire Lad, Red Champagne, and Warrington. Currants (Black), Baldwin's Champion, Carter's Champion, and Lee's Prolific; (Red), Ruby Castle, Red Dutch, and Reine Victoria; (White), Transparent and White Dutch.

Pruning Currants.—Established bushes of Red and White Currants should have the young shoots cut back to one bud from the old growth; leaving from 5 to 8 inches of young wood in pruning young bushes until they reach the desired dimensions. Black Currants, as well as Gooseberries, require different treatment. The young growths of established bushes should be thinned out (not spurred backed as is frequently done), and the lateral growths cut back to one bud, topping any of the young shoots retained to form the bushes that may be likely to touch the ground when heavily laden with berries. Cut out one of any shoots that cross each other, so that the centres of the bushes may be left open.

Planting Young Trees of Gooseberries and Currants.—In making plantations of Gooseberry and Currant bushes, a distance of 6 feet should be allowed between the rows, and between the bushes in the rows. The space between the rows and plants can be cropped with Cabbages, Cauliflowers, and Ashleaf Kidney Potatoes, until the bushes have attained to the full size. A good dressing of manure should be well dug into the land previous to planting. When planting the bushes take hold of the stem of each and shake it in an upward direction, the soil then trickling among all the roots, which should remain within 5 or 6 inches of the surface when the soil has been trodden and made level. When planting Gooseberry and Currant bushes in borders adjoining walks, and it may be to take the place of old exhausted bushes, prepare the holes about 15 inches in diameter and the same depth, and incorporate a few shovelfuls of short manure with the excavated soil. Should the staple be of a stiff nature, add a little leaf-soil, wood or coal ashes.

Strawberries.—If new plantations are to be made in the spring, the ground should be prepared by digging deeply into it a liberal dressing of manure; or better still, trenching it between 2 and 3 feet deep, according to the natural depth and quality of the land, breaking up and retaining the subsoil in the bottom of the trenches, and working in two or three layers of short dung. If the work is done at once, the subsoil ground will have ample time to settle before planting is done. For general use Royal Sovereign, Auguste Nicaise, and Sir Joseph Paxton are sterling varieties.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Newly Cauliflower.—A sowing of Cauliflower should now be made thinly in boxes or pans, selecting what is known to the trade as extra Early Forcing or First Crop, placing the boxes, &c., on a shelf in a house or pit heated from 55° to 60°. As soon as the plants have a true leaf, prick them off carefully into boxes filled with rich loam and leaf-mould in about equal proportions, at 4 inches apart each way, and replace them in full sunlight, admitting air carefully in increasing quantity till they get properly hardened off, in readiness for planting out about the end of March. For exhibition purposes, seeds of Sutton's Magnum Bonum may also be sown; and this variety being a little later than the first crop, and an excellent Cauliflower for any purpose, will form a succession. Autumn-sown plants in frames or hand-lights must be aired freely whenever there is no frost, the lights being removed when it does not rain or snow, and coverings of mats or litter only being used at night in the event of hard frost.

Early Cabbages, Lettuce, and Celery.—If the autumn-sown Cabbages are a failure, means should be taken to remedy this to some extent by sowing seeds of some good dwarf early variety in boxes, and growing them on similarly to Cauliflowers, for planting out of doors early in March. If properly grown and hardened, and given a warm position when planted, these become fit for use almost as soon as those planted out in the autumn. A little Lettuce seed should also now be sown, selecting a good early Cos variety for this sowing; or, if a Cabbage Lettuce be

preferred, some seeds of Commodore Nutt. Sow a pinch of Celery in a pan, and place in a Cucumber or Melon-pit till germination takes place, covering the seed very lightly with sandy soil, and a square of glass on the edges of the pan. For August and September use, nothing surpasses Sutton's Early Gem; whilst for early exhibition, nothing is better than Wright's Giant white, and Standard Bearer, red.

Leeks.—Where large and well-blanced Leeks are required early, seed may now be sown thinly in pans or boxes, placed in a gentle heat, and treated in the same manner that I advised for Onions. They may, however, be allowed to grow rather for a longer time in the seed boxes before being pricked off, using rich turfy loam, to which a good proportion of half-rotted leaf-mould has been added, all pressed firmly together in the boxes, allowing 3 inches space between the plants, and growing them for a time in a greenhouse or warm frame. If afforded a too high temperature, the plants will be likely to throw up flower-heads in the early summer. The plants being gradually hardened off may remain in the same boxes till the land is ready to receive them, towards the middle or end of April. The remains of last year's main crop may now be lifted and laid in on the north side of a wall or fence, where they will keep in good condition longer than if allowed to remain in the open quarter, the ground also being free for other uses.

Horseradish.—The present is a good time to make new or re-make old Horseradish beds, the ground being trenched to a good depth. If an old bed is to be re-planted, pick out every root, keeping the largest and cleanest for use, and the next size for planting; put a thick layer of rich manure at the bottom of every trench as the work proceeds, the roots being planted with the dibble in rows 2 feet apart, and 1 foot from set to set.

Parsley.—Should the supply of Parsley seem likely to be unequal to the demand, seed may be sown now in boxes, placing these in heat, pricking off the young plants when an inch high into a frame over a gentle bottom-heat, keeping them close for a few days till established. A supply from the same sowing would also be available for planting on a warm border in March, and will generally prove very useful.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton House, Luton.

Winter-flowering Carnations.—The time has arrived when these plants may be propagated by means of cuttings. First prepare a light kind of compost, having plenty of sharp sand or road grit incorporated in it, place four rather dry cuttings in 3-inch pots, make firm, afford water, and plunge in a gentle bottom-heat in a frame or forcing-house. In a month they will be ready to pot singly in 3-inch pots. Beware of letting water lodge in the axils of the leaves, and aim at getting them to strike quickly. If numerous cuttings are obtainable, any potfuls which appear to be stultborn may be thrown away, and another batch put in. Avoid excessive heat, or the constitution of the future plants will be weakened. A bottom-heat of 70°, and top-heat of 65°, should be maintained; gradually harden off the plants after the first pitting.

Canas.—These useful plants are gaining in public favour, and deservedly so, being of easy culture, ornamental, and free flowering. Here they are largely used for bedding-out purposes, and for that purpose they receive similar treatment to that afforded the Dahlia. For pot-culture, I prefer keeping and resting them in a cold house. A start may now be made with the batch intended to flower early. First prepare and mix thoroughly together, two parts of loam, one of leaf-mould, one of sand and dried cow-manure, with a small quantity of charcoal. To save time, place them in their flowering-pots, the size of which will depend on the size the plants are intended to reach; but for ordinary purposes, 8-inch pots will be found sufficiently large. Not much drainage is required, still it must be efficient. Shake out and select a few of the strongest crowns to be potted, cutting away the back part of the old rhizome; water well when potted, and place on a stage or shelf near the glass in the intermediate-house. Canas need an occasional fumigation.

General Work in the Plant House.—A pinch of seed of Begonias, Gloxinias, and *Celosias* may now be sown; and take cuttings of zonal *Calcegonias* if plants to flower in the autumn are wanted. Divide and re-pot plants of *Aspidistra lucida variegata* which may be

too large for general purposes, placing them in gentle heat to re-establish. The compost used for them must not be rich, or the variegation will disappear; but it may consist of one part loam, one leaf-soil, one road-grit, and one lime-rubble. On the plants getting established, remove them to a cooler house, and gradually harden them off. Cuttings of *Panicum variegatum*, rightly named Burmanni variegatum, for decorative purposes should now be taken, using 2 or 3-inch pots for them, as being the more useful size, and placing six cuttings in a mixture of loam, leaf-mould, and sand. They will readily root, and may then be removed to the side-stages of the stove or the conservatory. A good stock of *Isolpis gracilis* should now be potted up for similar purposes, dividing up old plants into small pieces, and using as before 3-inch pots. When the roots permeate the soil, afford plenty of water; and when root-bound, afford weak liquid-manure water, placing a saucer under each. *Carex variegata* and *Eulalia japonica variegata* may be similarly dealt with. Proceed with the propagation of foliage and other decorative plants too numerous to mention here, a little perseverance at this season saving time during the busier days to come.

THE ORCHID HOUSES.

By W. H. WAITE, Orchid Grower, Barford, Dorking.

Eulophiella Elisabethae.—Any of this comparatively new plant which are strongly rooted, and whose flower-spikes are beginning to push up from the base of the growth of the current season, should be afforded plenty of water at the root, taking care that the soil be not saturated with it, as the flower-spikes would then be liable to decay. Whilst the weather continues dull, the plant should be brought near to the roof-glass; but, although this species is not hurt by strong light at this season, it must not be direct sunlight, or the leaves will soon be injured. Those who have purchased plants recently imported, should place them in crocks only, as a commencement, and stand them in a shady part of a warm Cattleya-house, damping the stage and the sides of the pots once or twice daily, and in about one week water may be poured through the crocks several times a day. With this kind of treatment roots soon begin to grow, and potting is become necessary. For the proper growth of the plant, fly-peat, turfy-loam, and sphagnum-moss, in about equal parts, should be mixed together, and made warm before use. A moist shady corner of the hottest house may then be provided for them, and throughout the season of growth abundance of water should be supplied. It is a native of Madagascar, and terrestrial.

Miscellaneous Orchids.—I give under this heading some genera and species, which under cultivation present many difficulties.—*Bollea costalis*, *Pseca-tericia*, *P. Dayana*, *P. Klabechorum*, *P. Lehmanni*, *Huntleya mel-agris*, *H. Waiteana*, and *Batemania Bartii*. The plants will in most cases soon begin to make growth, which in some cases will render attention being paid to re-potting. Pots or pans of a suitable size being chosen, they should be half-filled with drainage, and rough peat, sphagnum-moss, and a moderate quantity of half-decayed leaf-soil. In re-potting a plant, raise it high above the rim of the pot on a cone of the above materials, and this is a very important point in maintaining a plant in a healthy state. At this season, all of these plants may be kept in the coolest part of the East India-house, shading them carefully from sunshine, affording water overhead once or twice daily, and the roots likewise as often as may be necessary, and moisture should be freely afforded during growth. The young roots are apt to be gnawed by woodlice, and traps should be set for these insects, or much damage will be done. *Stenia* (*Chondrorhyncha*) *pallida*, *S. Chesteronii*, and *Zygopetalum graadidiflorum* require a similar kind of treatment. *Habenaria rhodochila* is a plant that is now beginning to grow, and must have its tubers repotted forthwith. In doing this, turn them out of the pots, and probably more than one will be found in a pot. If an increase of the stock of this plant is required, repeat each tuber singly. The pots should be of a suitable depth, furnished with several pieces of crock at the bottom, upon which the base of the tuber should rest, the top being immediately below the rim of the pot; and having placed a tuber properly, proceed to fill up around it with smaller crocks to within one inch of the top, surfacing with the following mixture—peat and loam in equal parts, finely-chopped sphagnum-moss, a moderate quantity of finely-broken crocks in a coarse silver sand, just covering the tuber so that its point may be observed

through the compost. For a few days after re-potting no water will be required, and then an occasional sprinkling overhead with a fine rose watering-can will suffice to induce activity. When in full growth, an almost unlimited supply of water becomes necessary. This species of *Habenaria* is a native of China, and should not be grown in much warmth, or Thrips will soon play havoc with the leaves. A cool part of the intermediate-house is a suitable place for the plant at all times. The rare *Cymbidium Devonianum*, now commencing to push out its flower-spikes, will require close attention, to prevent these pushing down into the compost. The hybrid *Miltonia Goodiana*, and its varieties *nobilior* and *virginalis*, now throwing up their spikes, should be closely examined, to ascertain if Thrips are infesting them; and if any are present, take means to destroy them forthwith, or a whole year's labour will be lost.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leobury.

Pot-Vines.—Where Grapes are required at a very early date, pot-Vines become almost indispensable. If these were started with a view to obtaining ripe fruit at the end of March, or the beginning of April, the Vines should now be bearing the flowering stage, when they will require a higher temperature, a dryer atmosphere, and the bunches careful fertilisation. When the flowers are set, and the best bunches can be determined, remove the weaker ones, but leave from four to six bunches upon each Vine, according to its strength. As soon as the berries are large enough, they should be thinned, carefully removing small berries first; but early Grapes should not be thinned nearly so much as late ones. Afford the Vines a top-dressing of good loam, with a sprinkling of an efficient artificial fertiliser, and afford copious waterings with warm liquid-manure. If such helps to growth are neglected after the Grapes commence to swell, the result will not be satisfactory. Maintain the bottom-heat at 70° to 75° by the additions of warm leaves and stable-manure that have been prepared, and if some good loam be put on the top, and the roots exposed to the air, the growth of the new ones will also be conducive to a good finish in the Grapes. A moist growing temperature should be kept up by frequently damping down with liquid-manure during periods of hard frost, and especially at night.

Early Peach House.—If this house was started in November, the trees will now be passing out of flower, and may with safety be kept a little warmer. Afford the trees a moderate application of tepid water to encourage the fruit to commence swelling, and spray the trees with warm water at closing time upon warm sunny days. If the least sign of green fly should appear, destroy them by gentle fumi-gation, but taking care that the smoke does not become hot; several mild applications being better than one severe one. I find it is much safer to fumigate Peach-trees as soon as the fruit is quite set than afterwards, for when it has been necessary to fumigate in the later stages of growth, harm to the foliage has generally ensued. Do not dis-bud too soon, as it tends to check growth too early in the year, but when absolutely necessary, dis-bud very gradually by removing a few shoots each day from the more advanced branches. Careful attention to this detail, and in the matters of syringing, watering, and ventilating, will be likely to result in good, fully developed fruit, and healthy foliage.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropmore, Maidenhead.

Polegonium for Summer Bedding.—Owing to the fierce drought of the summer of last year, some varieties made so little growth that it was almost impossible to take cuttings; and where the stock is below the requirements, means should now be taken forthwith to propagate them. Assuming that the gardener has space in a warm house for the plants standing in pots and boxes, they may be potted-off singly, using for the purpose large 60's, and placed in the house, where, if subjected to a temperature of from 55° to 65°, they will soon establish themselves. In potting-off bedding-plants of this sort, it is unnecessary to use any crocks in the pots, but to employ a little of the roughest sittings of leaf-soil instead. As soon as the plants have grown a few inches in height, shoots fit for cuttings will be obtainable, which, if taken off at a joint and inserted singly in small pots, or four into a large 60, will soon root if the pots are placed on shelves over the hot-water pipes, or in a bed of warm leaves in a vinery or forcing pit. All

of the leaves should not be stripped off the cuttings, as if two or three are left, the cuttings will break the more freely, and sooner make bushy plants. If the leaf-stalks are much drawn, the better way is to take them off, leaving merely the terminal bud. Plants removed from the flower-beds in early autumn and potted may now be placed in heat to furnish cuttings. Where the stock of *Polegonium* is sufficient for future needs, the constant potting off need not take place till towards the end of next month, at which time in most gardens there are more houses in which to place them. The *petatum* or Ivy-leaved varieties are useful as cut-plants when of 2 or 3 feet in height, and plants of these should be potted on as may be required, placing a stick to each, to which the shoots should be loosely tied as growth goes on.

Fuchsias.—Of late years the *Fuchsia* has deservedly taken, as at a former period was the case, an important place in the summer flower garden; and the plants which were struck in the autumn of 1896 (which were, as I assume, potted early last month into 60's, and have been kept growing in a house furnished with a temperature of 50° to 60°, will now be well rooted and fit for shifting into larger, say 5-inch pots. The potting soil for the *Fuchsia* at this stage, should be moderately light and rich. After potting the plants stand them near the glass in a house with a temperature 5° higher day and night than that they previously occupied. Any plants that were potted up from the beds in the autumn, if cuttings are wanted, may be slightly pruned, and placed in gentle heat, the others being more severely pruned and kept cool for a time. *Fuchsia cuttings*, as soon as obtainable, will strike quickly in bottom-heat, then potted off; and when grown on quickly they make good plants by the end of the month of May. An excellent variety for summer-bedding is the old Madame Coralline, very free in flowering, and of a pleasing colour, that is, with dark-red sepals, and semi-double, white corolla. Lord Beaconsfield is another effective variety for this purpose, of tall growth, flowers large, single, a self-coloured rosy-carmine. Empress of Germany is a dark double-coraline, free-flowering variety, which is much used in Hyde Park. Ballet Girl, double-white, produces masses of bloom, and quickly makes a good pyramid. The well-known Mrs. Marshall is another good bedder. *F. gracilis variegata* is an excellent variety of slender growth, with variegated foliage; while *F. Meteor* is adapted for the edging of beds when pegged down, having leafage of a bright bronzy-red colour.

Evergreen Shrubs.—Among early-flowering evergreen shrubs, the *Androueda* takes a prominent position. *A. foribunda*, in a sheltered position, is just opening its first flowers. Being a fibrous-rooted plant, it may be moved at almost any time during the autumn or spring. *A. japonica*, with large flowers and longer racemes, blooms rather later, and is a desirable variety. *Androueda*, or *Zenobia speciosa*, a partly deciduous summer-flowering variety, with handsome spikes of large Lily of the Valley-like flowers, is not so often seen in gardens, although it is a desirable plant, which continues in bloom for a considerable period. *Viburnum Tinus* (*Laurestinus*) is well known; and of other useful shrubs for planting may be named—*Berberis Darwinii* and *B. stenocephala*, *Olearia Hassii*, varieties of *Persea nymuocata*, *Vaccinium ovatum*, and *V. obtusum*; *Acucos*, male and female; *Rhododendron* variety; *Kalmia*, and *Buddleia globosa*, which although not perfectly hardy, survives ordinary winters, and is a handsome flowering shrub. *Crataegus Lalandi*, when well berried, forms a conspicuous object in the shrubby borders, also *Arbutus Uuedo*, and *Andrachne*. *Hollies* in variety, with both gold and silver variegated forms.

THE SILVER WEDDING OF MR. AND MRS. T. **WILLIAMS**, Bleenheim Palace Gardens, was celebrated on Jan. 6, on which occasion his Grace the Duke of Marlborough sanctioned the use of the spacious corridors of the new south block of greenhouses, which were prettily decorated and illuminated for the purpose of entertaining the many friends, including the principal domestics at the palace, who had assembled to honour the event. Mr. and Mrs. W. were the recipients of numerous tokens of friendship and kindly congratulation, amongst others a handsome silver cake-basket, given by the garden employes, which will, no doubt, as we trust for many years to come be regarded as a most sincere expression of kindly sentiments.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MEETINGS.

SATURDAY,	JAN. 23	Royal Botanic Society meet.
WEDNESDAY,	JAN. 27	Renfrewshire Gardeners' Society meet.
SALES.		
MONDAY,	JAN. 25	Begonias, Gladioli, Tuberoses, Greenhouse Plants, &c., at Protheroe & Morris' Rooms.
TUESDAY,	JAN. 26	9700 Roses, Azaleas, Iris, Carnations, &c., at Protheroe & Morris' Rooms. Japanese Lilies, Rhododendrons, Palms, Begonias, Palm Seals, &c., at Protheroe & Morris' Rooms.
WEDNESDAY	JAN. 27	English and French Roses, Border Plants, Shrubs, Fruit Trees, &c., at Stevens' Rooms.
THURSDAY,	JAN. 28	Roses, Pionies, Gladioli, Clematis, &c., at Protheroe & Morris' Rooms. Liliums, Hardy Perennials, Bulbs, Roots, &c., at Stevens' Rooms. Azaleas, Hardy Bulbs, Liliums, &c., at Protheroe & Morris' Rooms.
FRIDAY,	JAN. 29	Orchids, from Messrs. F. Sander & Co., at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—38°-6°.

ACTUAL TEMPERATURES: LONDON.—JANUARY 20: Max., 39°; Min., 32°. PROVINCES.—JANUARY 20: Highest Temp., 49°, N. W. Ireland; Lowest, 31°.

AMONG the numerous proposals for adequately commemorating the "diamond Jubilee" of our QUEEN, we can, of course, only mention here those that have some direct connection with horticulture. Among these we may call attention to a scheme issued jointly by the Commons Preservation Society, the Kyrle Society, the Metropolitan Public Gardens Association, and the National Trust for Places of Historic Interest or Natural Beauty. Some years since we made inquiries into the provision made in our great towns to secure open spaces for sanitary purposes, as well as for recreation. The general result showed that London and most of our great towns were now well provided with commons, parks, or pleasure-grounds at a distance from their centres; but that there was, as there still is, a great necessity for numerous open spaces as large and as attractive as possible in the more crowded districts of our large towns. The incidence of disease and death is

disproportionate in such areas, to say nothing of the deficiency in the amenities of life. It is impossible, therefore, not to sympathise with the efforts that are being made to purify and beautify our great towns, and to add to the comfort and enjoyment of the citizens. A circular before us says:—

"Our idea is that locality which is taking common action for the purpose, may fitly provide for itself a plot of ground, or place of natural beauty or historic interest, to be dedicated to the common use and enjoyment of its people. This may be called a 'Queen Victoria' garden, park, playground, memorial, field, or whatever name indicates its destined use.

We venture to suggest the following considerations in support of our idea:—

(a) In the metropolis, and in all populous and growing towns, the inadequate supply of open space is generally recognised. In view of our rapidly increasing urban populations, there are very few towns sufficiently provided in this respect, or in which it is not expedient to secure more parks or playgrounds.

(b) In rural districts there is a great deal of liberality shown by landowners in the allowing of the use of their ground. But that is all subject to changes of ownership and to calls for other uses. It is desirable for people to have places of their own which are secured to them in their own right. Where there are no greens or commons, the children of the poor have often only the lanes and roads as playgrounds. They may not ramble in woods and along hedge-rows, and thus their high spirits, instead of finding vent in play and games, often result in mischief, and lead to serious trouble.

(c) Places dedicated to public recreation afford the largest social range of enjoyment. Not the poor only, but all classes: young, old, rich, poor, ailing, well, good and bad, can enjoy a common ground. That is very fitting for a National Memorial.

(d) Such a dedication is a form of donation that can do no harm to any one, for it cannot pauperise people or injure their self-dependence, as it is a boon they cannot possibly procure for themselves.

(e) Memorials in this shape also afford a greater chance of permanence in point of time. There are few institutions which do not become unsuitable by changes of habit and circumstances, whereas it is difficult to look forward to a time when an open space or some feature of natural beauty will not be a valued possession. This element of permanence also is very fitting for a National Memorial.

(f) The great difficulty found in permanent institutions is the amount of management they require, which, after the first interest of the founders has passed away, is not apt to be forthcoming, except through paid agencies, which are liable to become rigid and mechanical. Open spaces require less management, as they are hardly capable of diversion from their object, and the visible character of their condition, and the constant presence of those interested, are securities that defects in management will speedily be brought to the notice of their managers.

(g) The recent extension of Local Government affords new and great facilities for the ownership and management of endowments of a local nature, such as we have in view.

We will re-state in somewhat more expanded form the plan which is before our minds. We aim at connecting the memory of the Queen with something which will permanently make a neighbourhood more healthy, more agreeable, or more interesting to live in. The exact form which such a memorial would take might vary largely in different places. In near proximity to a common or heath, no memorial would be more fitting than to place such common or heath under local management, by means of a Provisional Order, made under the Commons Act, 1876; and the consent of the Lord of the Manor to such an order would be his gift in celebration of the Queen's reign. In places where there exists some hill-top commanding extensive views, some piece of woodland or of water, of beauty and

of value to the neighbourhood as a place of resort, some waterfall, some sea-cliff, or other place of natural beauty, the dedication of this to the public would be the best expression of the idea we wish to suggest. In other places, again, where no common lands remain, and there is no exceptional charm of scenery, the best memorial would be the provision and dedication to the public of a garden, park, or playground; and in other cases, perhaps, the definite dedication to the public of a valued but doubtful right of way, or the formation of a new road or foot-path affording an agreeable drive or walk in the surrounding country, or the planting of memorial trees in appropriate places. Again, in the Metropolis and other towns, there may be square gardens or disused burial grounds, or other lands, which have been hitherto, by some accident, saved from the builder, but which are doomed either to absorption into the surrounding areas of bricks and mortar, or to waste and neglect; to recover such spots, and place them under the management of the town authority, would be an invaluable memorial of the Sovereign's long and beneficial rule. Finally, there may be some earth-work or ruin of great interest, or even some building of rare architectural beauty or historic associations, which might be purchased and devoted to some public purpose, and which would form a possession of unique value for future generations. In one or other of these ways the amenities of the neighbourhood may be permanently enhanced, and a lasting memory of the Victorian reign preserved, in a form which would be a permanent source of pleasure and interest to the inhabitants.

Lord HOBHOUSE is chairman of the joint committee; and Messrs. EAST HOLMES, 83, Lancaster Gate, London, W., and LAWRENCE W. CRUICK, 1, Great College Street, London, S.W., are hon. secretaries to the joint committee, to either of whom communications may be addressed. *December, 1896.*"

ROYAL HORTICULTURAL SOCIETY.—It is proposed that NORMAN C. COOKSON, WILLIAM MARSHALL, and H. J. VEITCH, be elected members of the Council at the annual meeting on February 9, in place of Sir ALEXANDER ARBUTHNOT, GEORGE BUNYARD, and HENRY J. PEARSON.

THE VICTORIAN MEDAL.—In connection with the three concluding paragraphs of the Report of the Council, which is now in the hands of the fellows (see p. 66), the following letters, kindly furnished by Rev. W. W. WILKS, may be of interest to our readers:—

"December 18, 1896.
"Sir,—I am desired by the Council of the Royal Horticultural Society to ask you to lay before Her Gracious Majesty the Queen, patron of the society, a proposal which they beg leave to bring before their fellows, for the establishment of a medal or medallion in celebration of the attainment by Her Majesty, in 1897, of the 60th year of her happy, prosperous, and beneficent reign. With Her Majesty's gracious permission and approval, the council wish to name their medal The Royal Horticultural Society's 'Victoria Medal,' and their proposal is that it should be awarded by the society, 'Honoris Causa,' to certain number of persons distinguished for their services to horticulture, or eminent in the science and art of gardening. The council express a confident belief that no such distinction exists at present, and that the institution of such a 'Medal of Horticulture' would be received with a qualified favour by Her Majesty's garden-loving subjects. They therefore venture humbly to hope that their proposal may meet with Her Majesty's gracious consent and approval.

"I have the honour to be your obedient servant,
"TREVOR LAWRENCE,
"President."

Rt. Hon. Sir FLEETWOOD EDWARDS, K.C.L.E.

"Osborne, December 23, 1896.
"Sir,—In reply to your letter of the 18th inst., which I have had before the Queen, I am commanded to express Her Majesty's regret that she can only refrain in this instance as in all similar cases, from giving any personal opinion with reference to any specific proposal for the commemoration of the 60th anniversary of the reign. At the same time the Queen has no possible objection to raise to the establishment of the medal referred to, or to the name that it is proposed should be given to it—and they would appear to be points that rest with the council of the Royal Horticultural Society.

"I am, Dear Sir,
"Yours faithfully,
"(Signed) FLEETWOOD J. EDWARDS."
Sir TREVOR LAWRENCE, Bart.

BULBOPHYLLUM ERICSSONI, *Kraenzlin*, n. sp.—By the kindness of the Hon. WALTER ROTH-CHILD, we are enabled to give an illustration (fig. 16) of this remarkable species, which was imported a few years ago by Messrs. F. SAYER & Co., St. Albans, through their enterprising Swedish collector, Ericsson. It was described from dried specimens sent by that collector

slender flower-stalk, and you will get an idea of this extraordinary new *Bulbophyllum*. The flowers have a yellowish white ground colour, the sepals and petals are heavily spotted with dark brown, the lip is red, and has a very strange spongy texture at its base.' Not only is the species remarkable for its showy flowers, but its large shiny green leaves sur-

round the slender flower-stalk, and you will get an idea of this extraordinary new *Bulbophyllum*. The flowers have a yellowish white ground colour, the sepals and petals are heavily spotted with dark brown, the lip is red, and has a very strange spongy texture at its base.' Not only is the species remarkable for its showy flowers, but its large shiny green leaves sur-

round the slender flower-stalk, and you will get an idea of this extraordinary new *Bulbophyllum*. The flowers have a yellowish white ground colour, the sepals and petals are heavily spotted with dark brown, the lip is red, and has a very strange spongy texture at its base.' Not only is the species remarkable for its showy flowers, but its large shiny green leaves sur-

FIG. 16.—*BULBOPHYLLUM ERICSSONI*.

to MESSRS. SAYER, by Dr. KRANZLIN, in the *Gardeners' Chronicle*, October 28, 1893, p. 522. The illustration represents a very fine and distinct new species; and a still stronger specimen, which is sending up two stout flower-spikes in the Hon. WALTER ROTH-CHILD'S collection, may probably quite come up to the words of Dr. KRANZLIN'S description:—"This is by far the most striking new Orchid received for some time past. Imagine a group of from nine to twelve flowers of a large Chimeroid *Mastodevalla*, surmounting a

mounting its long and rather slender pseudo-bulbs. render it an ornamental plant when not in bloom. It is probably a native of New Guinea, and therefore a warm-house plant.

VEITCH MEMORIAL FUND. The Veitch Memorial Trustees have decided to present, this year, a large Silver Medal for distinguished service to horticulture, to each of the following gentlemen:—
To NORMAN C. COOKSON, Esq., of Oakwood,

and beautiful varieties have been raised, especially in the Malmaison section, and among those which, on account of their hardihood and beauty, are adapted for culture in the open border.

To Professor L. H. BAILEY, of Cornell University, Ithaca, N.Y., in recognition of his efforts, by means of his lectures and his writings, to place the cultivation of plants on a scientific basis; to promote the extension of horticultural education, and, by numerous trials and experiments, to improve and

render more productive, plants grown for economic purposes.

TO CHARLES NAUDIN, of Antibes, a distinguished French botanist and horticulturist, who, by his prolonged series of experiments and observations, has much advanced the theory and practice of hybridisation. M. NAUDIN has also been highly successful in introducing, cultivating, and distributing a large number of plants of great economic importance, and of thus enhancing the resources not only of his own, but of other countries.

TO HERR MAX LEICHLIN, of Baden-Baden, as one who has rendered eminent service to horticulture by the introduction of a large number of interesting plants, and who has displayed equal sagacity and skill in their cultivation.

The Trustees have also decided upon placing a medal and prize of £5 at the disposal of the Shropshire Horticultural Society, to be competed for at their Great Commemorative Exhibition in August next; and have allotted a similar Medal and prize of £5 to the Trentham Horticultural Society.

HORTICULTURAL CLUB.—The monthly dinner and concert-course took place at the Hotel Windsor on Tuesday, 12th inst. The chair was taken by Mr. HARRY JAS. VETCH (Vice-chairman of the Club). The subject for discussion was "The Proposals for Horticultural Memorials of the Queen's Reign," which was opened by the secretary, Rev. H. H. D'OMBRAIN, who passed in review the various proposals which had been advanced in the gardening journals, and expressed his opinion, that not one of them was practicable, and that as far as a Horticultural Institute, of whatever character it might be, was concerned, there was no situation in London that could be considered eligible; that what was required was not so much a hall where large shows could be held as a home where such fortnightly meetings as those of the Royal Horticultural Society could be held, together with some suitable offices for committee meetings and horticultural gatherings, which must be held in a central position alike suitable for the provincial and the suburban exhibitors. A discussion took place, and the general opinion was that, with the air full of schemes for the popular celebration of the 60th year of the Queen's beneficent reign, the year 1897 was not a good time to launch a scheme for the national benefit of horticulture, more especially after Her Majesty had herself indicated that what would be most acceptable to her would be the strengthening of the nursing institutions, hospitals, and other works of mercy for the relief of the suffering and poverty-stricken masses of the people. Horticulturists would have a good opportunity presented to them of following this particular line in strengthening the new "Victorian Era Fund" about to be raised by the Gardeners' Royal Eucalyptus Institution, particulars of which appeared in our issue for the 15th inst.

AMERICAN FRUIT IN VIENNA.—Apples and Pears from the United States, Canada, &c., have been selling, as we learn from an Austrian contemporary, on the Vienna market, the first at from 5*d.* to 8*d.*, and the latter from 3*d.* to 1*s.* per kilogram. The quality is good, the exporters fully understanding that only good wares would sell at a profit. The fruit-growers of Great Britain are, therefore, not alone in experiencing the competition of the American in the home-markets. This may, this season, have been enhanced by the enormous fruit-crop of excellent quality harvested in America, accentuated by the smallness of the crops on the continent.

PRUNING THE WALNUT-TREE.—The pruning of the Walnut-tree should never be performed during a period of frost, nor yet after growth has begun, as that leads to bleeding, as in the Vine; but in the spring, just before growth recommences.

AGRICULTURAL EDUCATION IN ABERDEEN UNIVERSITY.—Since the changes were made in the teaching of agriculture in the Aberdeen University, those in charge have not allowed the grass to grow under their feet. A new popular class has been

started for those who have had little or no previous scientific training in the subject, by Mr. WILSON (Lecturer in Agriculture), Mr. HENDRICK (Agricultural Chemistry), and Mr. YOUNG (Veterinary Science), with great spirit, on their own responsibility; and the creditable efforts of these gentlemen to popularise the subject deserves every encouragement. The course lasts for a month, the classes being held daily (except Saturday), from 1.30 to 5 P.M.

DIMORPHIC CYPRIPEDIUM.—MESSRS. SANDER & CO., obligingly send us a curious sport, which derives additional interest from the legal proceedings which have lately taken place with reference to similar sports. The plant in question is *Cypripedium Danthieri*. In some years, as we are informed, all the flowers are of the usual character, whilst in other years all the flowers produced are smaller in size, thinner in texture, pale in colour, indeed quite free from the rich violet colouring of the nerves of the dorsal sepal. This year the plant has produced one of those degenerate flowers at the same time as the normal blooms. The flowers have been on our table for several days, and it is curious to observe, as we write, how the typical flower preserves its brilliancy of colour and firmness of texture, in spite of the foggy atmosphere to which it has been subjected. The other flower is limp and wretched, its segments all depressed, and of the colour of a dirty rag. The stamens and stigma are, except in size and colour, similar in the two flowers. We do not hear that the foliage of the plant is subject to the same degeneration.

"ATLAS DES PLANTES DES JARDINS ET D'APPARTEMENTS." Par D. BOIS. Paris: KLEINKSIECK. (Text, 432 pp. 8vo; 329 coloured plates.) This is a series of coloured plates, accompanied by a descriptive text, and devoted to a selection of the plants most frequently met with in cultivation by amateurs. It is therefore intended more particularly for those who are not professed gardeners. To them in particular, and to gardeners in general, we commend these volumes. The information given is no compilation, such as is commonly the case in horticultural literature of this class; but it is, within its limitations, an original book, indicating much research, observation, and judgment. Of the plates also we can speak in terms of high praise; they are accurate and faithful—not exaggerated, and containing details not often found in such works. The only defect we can point out is that the artist has occasionally selected for representation specimens of poor varieties that do not do justice to the plant; take, for instance, t. 290, representing *Lilium speciosum*. We fear the bulb-merchant would not secure many customers if the flowers produced from his bulbs were not of better quality than that represented in the plate in question. A like remark might be made of t. 248—*Lycaste Skinneri*; and of the *Masdevallias* on plate 243.

HAMPTON COURT PALACE GARDENS.—We understand that Mr. A. GRAHAM, who has been superintendent of these gardens for a period of about twenty years, and who made effective use of carpet-bedding there, has resigned; and is succeeded by Mr. GARDINER, superintendent of Greenwich Park Gardens.

MR. FRED TURNER, F.L.S., has recently been offered and has accepted the position of consulting botanist to the West Australian Government in succession to the late Baron F. von MOELLER. Mr. TURNER's work will principally consist in naming and describing the economic plants of the western colony. In the first instance, he will name and describe all the forage plants and grasses, so that the pastoralists and farmers who are settled there may know of what their pastures are composed, supposed poisonous plants, noxious weeds, &c. This work will be done in a similar way to that done by Mr. TURNER for the pastoralists and farmers of Queensland under instructions from the New South Wales Government. Mr. TURNER is the author of numerous illustrated and descriptive works, on "Australian Grasses," and other economic subjects. The work

in connection with the West Australian flora will not necessitate Mr. TURNER's leaving Sydney, so that pastoralists, farmers, nurserymen, and others who have been accustomed to send him botanical specimens to be identified and described can forward them as usual.

PINE-APPLE: ANALYSIS AND MANURE.—The October *Bulletin* of the Botanical Department, Jamaica, contains the following notes on the Pine-apple by Mr. J. J. BOWREY, F.S.C., F.L.C., Island Chemist—

ASH OF PINE-APPLE.	
Potash K ₂ O	49.41
Chloride of Potassium KCl	8.81
Chloride of Sodium NaCl	17.91
Magnesia MgO	8.83
Lime CaO	14.15
Phosphoric Acid P ₂ O ₅	4.98
Sulphuric Acid H ₂ SO ₄	Trace
Silica SiO ₂	4.04
Phosphate of Peroxide of Iron	2.93
	99.29

Judging from this analysis of the ash of the Pine-apple, potash is the most important mineral substance which it requires. Of course phosphoric acid is also necessary, and so are lime, magnesia, and iron, but it must be a very rare soil which does not contain iron and magnesia in ample quantity, and usually there is enough lime also present. It is difficult to make suggestions respecting manuring in total ignorance of the nature of the soil to be manured. But certainly no harm can be done, and probably much good, by adding phosphoric acid and potash to the soil; the former best as finely ground basic slag or Thomas' phosphate powder, price about 55*s.* per ton, f. o. b., in England. A dressing of from 5 to 10 cwt. per acre will supply phosphoric acid for three or four years, and also some quantity of lime. The potash can, I think, be imported into Jamaica most cheaply as chloride of potash; its price is about 48 per ton, f. o. b., in England. From $\frac{1}{2}$ to 1 cwt. per acre would be a dressing for a year. But the Pine-apple also needs nitrogen for its growth; this might be supplied as nitrate of soda at £10 per ton,—giving one cwt. per acre when the plants have started to grow rapidly.

THE SURVEYORS' INSTITUTION.—The next Ordinary General Meeting will be held on Monday, January 25, 1897, when the adjourned discussion on the paper read by Mr. HOWARD MARTIN (Fellow), at the last meeting, entitled "The Future Development of the Surveyors' Institution," will be resumed. The chair to be taken at 8 o'clock. It has been found desirable to alter the date of the Annual Dinner from Wednesday, March 3 (the date given on the Calendar), to Wednesday, February 24. The dinner will take place at the Hotel Cecil.

THE WEATHER.—The character of the weather has greatly changed since our last issue, the temperature becoming much colder, with snowfalls in London and the southern parts of the country generally. From Salisbury and Cambridge we learn that frost of 11° severity was experienced on Sunday night.

THE ULSTER HORTICULTURAL SOCIETY.—An encouraging report was presented to the annual meeting of the Ulster Horticultural Society, which was held recently, Mr. JAS. JOHNSTON, J.P., presiding. This is one of the more flourishing of the Irish horticultural societies. The position of the Society is steadily improving, and its show (see fig. 17) held in November was much in advance of any previous one. Moreover, the weather being fine, the receipts were greater than on any previous occasion. The fine displays of *Chrysanthemums*, cut flowers, and fruit, are especially commented upon. At this show a new and interesting feature was the Veitch Memorial Prize competition for the best group of stove and greenhouse plants, which was worthily won by Mr. GRAY, of J. B. HIRSTON, Esq. The receipts from all sources amounted during the year to £265 6*s.* 1*d.*, as against an expenditure of £181 14*s.*, leaving a total balance in hand of £84 18*s.* 5*d.* It was mentioned in the course of the meeting that the Society

would celebrate the diamond jubilee of the year by offering a prize of £100 for cut blooms, open to the whole United Kingdom. The prize will be named, 'The Lady Mayoress Victoria Jubilee Championship Prize.'

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The annual general meeting of the Reading and District Gardeners' Mutual Improvement Association was held in the club room on Monday, January 11, Mr. T. NEVE, the chairman of the association, presiding over a large gathering of the members. After the report and balance sheet, which were of a very satisfactory character, had been read and adopted, the following members were elected to fill the various offices during the ensuing year:—President, Mr. C. B. STEVENS; chairman, Mr. T. NEVE; vice-chairman, Mr. E. DEARLOVE; librarian, Mr. JAS. MARTIN; assistant-librarian, Mr. E. DORE; treasurer, Mr. W. PHIPPS; secretary, Mr. J. POUND, Junior. A very

standard on the upper white portion bears many purple markings; ornatum, the arrangement of spots on the standard in three different sizes had a curious effect. Other good varieties we have no space to mention. M. LINDEN sent also two varieties of *Cypripedium Lelandianum*, one remarkable for the good proportions of the flower. C. Lawrenceanum Moortebeckiense, from MM. L. LINDEN ET CIE., had a large and unusually dark standard; C. microchilum (from the same exhibitors), was very distinct-looking. M. MOENS showed C. Memoria Moensi and C. Laddensis. Phajus × Martine (P. Blumei × tuberosolosis), from M. A. VAN INSCHOU, was remarkable for richness of colouring; Cattleya Trianoi lucida, from M. LINDEN, is pure white with a lip, delicate yellow in the throat, purple at the base, and with a frilled white edge; Odontoglossum × flavo-marginatum, also from M. INSCHOU, has all the divisions of the flower bordered with yellow; *Oncidium Phalaenopsis punctatum*, the whole flower faintly speckled, is a gem; *Mesaspidium*

which had been sown thickly, and also with plants raised from thinly-sown seeds; also showing roots a year old, from which fruit was cut at the end of December. The discourse was instructive, and the members present were invited to put questions to the lecturer, which many of them did. A number of plants in flower or berry were exhibited, chiefly *Primulas*, *Cyclamens*, and *Solanums*.

THE WOLVERHAMPTON FLORAL FETE for the present year has been fixed for July 13, 14, and 15. It will be held in the Public Park.

SCILLY.—According to the *Western Morning News*, the first special train of flowers from the Isles of Scilly for the season was despatched on Tuesday, 12th inst., from Penzance for the London, Midland, and Northern markets. The consignment consisted of about 1800 packages, weighing between 10 and 11 tons, and the train consisted of five vehicles. The Broccoli trade from West Cornwall has also commenced in earnest last week, and on Monday three special trains were despatched. Up to the present very fair prices have been realised.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—The monthly meeting of this society was held at their room, 25, Westgate Road, on Tuesday evening last. Mr. BULLOCK occupied the chair, and there was a good attendance of members. Mr. DAVIES, gr. at Thornhill Towers, Sunderland, read a paper on the "Odontoglossum," which was very much appreciated. An excellent discussion followed, in which many took part.

EFFECTS IN EXHIBITION.

THE art of arranging plants for exhibition purposes affords an excellent opportunity for the display of artistic taste, as well as originality of conception. In regard to the disposition of plants in groups, we have frequently expressed the opinion that the continental shows are much before the majority of our own. At York and Shrewsbury the grouping is always good; but the plants used in both cases are, for the most part, usually of a dwarf character, and the effect, though excellent in its kind, is not that which may be obtained with a free use of large, handsome Tree-Ferns, graceful specimen Palms, and other plants. At few of the exhibitions is landscape effect in a free, bold manner, attempted, and we therefore reproduce a photograph (fig. 17) that represents an exhibit by Mr. McKinnon, Curator of the Botanical Gardens, Belfast, at the Chrysanthemum show held by the Ulster Horticultural Society in November last. The exhibit is a successful imitation of a landscape scene, and includes a miniature lake, rockwork, a fountain, and glen effect. The background appears to be particularly appropriate, and the Tree-Fern, Palm, Dracæna, and Bamboos, are convenient in size and form.

We have been favoured with a photograph also from Mr. Thos. Paul, Hon. Sec., which represents a collection of stove and greenhouse plants exhibited at the same show by Mr. Thos. Gray, gr. to J. B. Houston, Esq., Orangefield, Belfast, an exhibit that was distinguished by an award of the Veitch Memorial Medal. Though the plants appear to be worthy of every commendation, the photograph itself is not so suggestive in character as the one we have reproduced.

PLANT NOTES.

A HYBRID CINCERARIA.

THERE is flowering in the Botanical Gardens, Sheffield, a plant of *Cinceraria*, distinct from any other with which I am acquainted, and which, judging from its appearance, will make a welcome greenhouse plant for flowering in the winter months. The plant commenced to flower in a cool house two months ago,

FIG. 17.—A GROUP OF PLANTS, ARRANGED BY MR. MCKINNON, AT THE EXHIBITION OF THE ULSTER HORTICULTURAL SOCIETY.

hearty vote of thanks was passed to the retiring president, Mr. ARTHUR W. SUTTON, for the great interest he had shown in the association during his term of office. A beautiful collection of *Primula obovata* was shown by Mr. TOWNSEND, gr. to Sir WILLIAM FARRER, Sandhurst Lodge, and was greatly admired.

MEETING OF THE BRUSSELS ORCHIDÉENNE.

—Among other exhibits at the last meeting were thirty plants of *Cypripedium insigne* from MM. LUCIEN LINDEN ET CIE., of Moortebeck. These *Orchids* were all so fine, that to solve the difficulty of deciding which of them were the best the jury voted, with the result that the following varieties received awards:—*pictissatum (nominale)*, the standard of which is spotted with purple on a white ground, and the form and colouring are exceptional; *fuscum*, standard all mahogany-brown, well set off by a wide white margin; *tigrinum*, very spreading standard, with large spots; *superbium*, a fine flower, the standard with a very wide white edge; *Campanbergii*, standard round, fresh green, with large spots and wide white margin; *illustre*, standard and lower sepal large, the latter with several lines of dots, the

vulcanicum maximum, with a raceme of seventeen beautiful flowers, won a Diploma of Honour à l'unanimité for M. LINDEN, and a First class Diploma of Honour was also awarded to him for *Mesaspidium minutum*, in which the usual colouring of miniature was seen beautified with a shade of gold. *Cattleya Trianoi cinctis* is of a delicate rosy tint; and a *Laelia autumnalis*, from M. VAN WAMBERG, was exceptionally fine. M. LINDEN also sent *Odontoglossum crispum musicum*; *O. crispum arosium* (Diploma of Honour), *O. Humevallianum maximum*, *Cattleya × Lombardiana*, of a beautiful lilac-purple colouring, and very elegant (First-class Diploma of Honour), and other varieties. From the Royal Estates at Laeken came a fine plant of *Odontoglossum crispum*, a fine variety, with four racemes of blooms, two being of unusual length *Ch. de B.*

WINCHESTER GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—On Tuesday the 12th inst. at a meeting of the above association, Mr. CURTIS, gr. to W. F. G. SPRANGER, Esq., Springhills, Southampton, read a paper on "Tomato Culture under Glass," illustrating his remarks with plants, the seeds of

and it is still in flower. The habit of the plant is shrubby, thereby differing from *C. creuata* which is herbaceous, like the common garden *Cineraria*; the leaves are somewhat small, and not unlike those of *C. lanata*, although the stems and under-surface of the leaves are less white and woolly than is the case in that species. The flowers are about $\frac{1}{2}$ inch in diameter, and the colour approaches magenta. It has the appearance of being a hybrid between *C. lanata* and *C. creuata*, the character of both these species being well marked in the plant. Our attempt to raise it from seed has been unsuccessful, but it is easily propagated by means of cuttings put in a close frame in a cool house. *William Hurron, Jan. 1.*

INDIA.

We have briefly called attention to some remarkable publications lately issued from the Calcutta Botanic Garden, under the superintendence and largely under the authorship of Dr. King. They comprise three parts of the *Annals of the Royal Botanic Garden, Calcutta*, and when all the difficulties and drawbacks are considered, constitute, as we have said, some remarkable publications reflecting the greatest credit on the energy and capacity of authors and editor. The second part of the fifth volume contains a *Century of New and Rare Indian Plants*, described by Mr. P. Brühl, Dr. D. Prain, and Dr. George King. Mr. Brühl alludes to the necessity of studying the botany of the districts mentioned by Caspar Bauhin, Gouan, Galetaria, and others, of tracing the relation of the flora of the North-west Himalayas and the Caucasus, and of establishing the affinities between the flora of the Central and Eastern Himalayas and that of Japan. The botany of the extreme Eastern Himalayas is said to be all but unknown. "The results of the partial explorations of the Clunder valley, very clearly indicate the close relationship of the flora of the Himalayas east of Sikkim to the floras of Yunnan, Hupeh, Setchwan, and Kansu, point to a rich harvest, which is ready to be gathered in the inhospitable regions which stretch from the eastern frontier of Sikkim to the heights of the Mishmis and Alos."

The first part of the sixth volume contains a remarkable memoir, by Brigade-Surgeon Lieutenant-Colonel Cunningham, on the *Causas of the Fluctuations in the amount of Turpentine in the Motor Organs of Leaves*. The object of the author is to show that these movements are not due to irritability of the protoplasm, but to purely physical processes, dependent on osmosis, or on alterations in the relations existing between local supply and loss of water.

Details of a large number of experiments are given as well as coloured illustrations of the phenomena observed. An excellent index accompanies the memoir, which deserves and will obtain the careful consideration of physiological botanists.

The same author contributes an account of a disease affecting the leaves of *Iponoxea rubro-cerulea* by a parasitic fungus, *Chaenophora Simsoni*, which is of special interest as showing a kind of starting-point from which various groups, both of the higher and all lower fungi, radiate. From a physiological and genealogical standpoint, this new fungus deserves the closest attention.

The seventh volume of the *Annals*, lately issued, contains a monograph of the *Batabase of British India* by Mr. J. S. Gamble, the Director of the Imperial Forest School at Dum-Dum. It does not need a specialist to divine that this is a model monograph. In the introduction, details are given as to the literature of the subject, the morphological structure and geographical distribution of the species. These are distributed through—1, North West India; 2, Central India; 3, the Western Ghats; 4, Ceylon; 5, Bengal; 6, Burma; and 7, Malaya. One hundred and fifteen species are described, nearly twice as many as were known to Muir from the same countries. The sheaths of the culms vary in different species, and supply good points of distinction in their texture, covering, and form. The sheath are

understood includes the sheathing petiole, the abortive lamina, and the ligule. As to the nervation, Mr. Gamble quotes Kurz, who says little value can be attached to the size, shape, and nervation of Bamboo leaves. Transverse veinlets, according to Mr. Gamble, occur only in the genera *Arundinaria* and *Phyllostachys*; in others, what appear to be transverse veinlets are not really such, but are caused by glands, which in fresh specimens are seen through the leaf as pellucid dots, and in dried specimens as raised lines, giving the appearance of cross-bars between two neighbouring intermediate veins.

The descriptive text, which is carefully drawn up and methodically arranged, is accompanied by 119 lithographic quarto plates, giving the floral and other details. Botanists and foresters have now at their disposal a monograph which will not only prove of scientific interest, but of great practical value. We venture to congratulate the author and authorities of the Calcutta Garden on this satisfactory production, and appreciate the wisdom of the Government in sanctioning its publication.

FORCING RHUBARB: CULTURE OF ROOTS.

As regards the forcing of Rhubarb, I do not intend to make many remarks, as almost every reader of the *Gardeners' Chronicle* knows how to do that. But there are differences in the produce from the varieties each will afford, and some are early, others late, in striking; the position the roots occupy when growing has also an influence on the plants. It is surprising how soon plants fit for forcing can be obtained from seed, but these cannot be relied upon as being true to name, with the consequence that some are late and some early. These should be marked with labels, so that in taking up roots for forcing only the early-growing varieties are dug up. If seed be sown early in the spring in rich soil in rows 2 to 3 feet apart, the seedlings may be thinned in the row to half that distance; and as some of the plants will take the lead, I carefully lift the strongest, and transplant them, and though they may the following season lack the size of other roots they are earlier in starting, and therefore of value where large quantities of stalks are required. The forwardest of the seedlings the next season will be found to be much earlier than one would suppose would be the case in plants from one and the same sowing. These plants lift well as early in the winter as may be required, and soon turn in. Another important detail in Rhubarb for forcing, whether of seedlings or otherwise, is not to weaken the growth by pulling much of the growth during the summer, as, although the plants soon appear to recover from the mutilation, with seedlings every encouragement should be given the plant to make strong crowns, and to this end all leaf-growth should be left untouched. My remarks are not meant to apply to roots of large size, with many crowns or buds that are not intended for forcing.

Sowing seed, and growing on the plants solely or in great part for forcing, is not the only method practised, although I would strongly recommend it. Division of the root, when properly carried out, and good attention is paid to cultural details, answers well enough. Divisions of the root take at the least two years before fair-sized crowns form if no extra attention be given them, and the stalks are drawn for use. This is a point which gardeners often overlook, hence I lay more stress upon the necessity of good summer culture. I do not prefer seedlings to roots obtained by division, but when special culture is pursued with Rhubarb from seeds the results are better. Rhubarb requires deeply trenched soil, plenty of manure, and the plants when growing are the better for occasional doses of liquid manure; but overcrowding must be guarded against by wide planting.

For some years my method was to plant a small quarter of Rhubarb yearly for forcing purposes, till I was induced to try seed, splitting up the roots in the usual manner, and affording the above methods of cul-

ture, but the roots were seldom strong enough in one year for the forcing-house, although a few might be. I found seed gave much better plants, and they took very little more time. When making a new plantation with divided roots, only the younger buds or crowns near the outside should be made use of, all decayed parts being rejected. If a few roots only are required, select some of the strongest side buds, and plant a piece of land yearly. Rhubarb is frequently planted in odd corners, but it is better to give it an open position, say single lines here and there, and treat it liberally, as, if neglected, the plant soon deteriorates. If the plant must be grown on shallow soils, special care should be taken by preparing broad trenches as for Celery, throwing out and wheeling away the gravelly, sandy, or chalky subsoil as the case may be, and substituting better soil incorporated with manure. Much water in dry weather will be required by the plants in such soils, and this is a matter which must not be neglected; nor rich mulching. The crowns also benefit by a little cover being placed over them in severe weather.

A few words as to varieties. To bear bard forcing, no variety is better than the Royal Albert, or as it is better known, Early Red, a favourite market Rhubarb on account of the size of the stalks. For many years Johnston St. Martin's was our earliest variety, and I do not think it is yet beaten for earliness, but in poor soils, it is not large, although of good colour. Many gardeners fore the less well-known Hawke's Champagne, a grand variety as regards quality and productiveness, but not so early as Royal Albert; still, it is one of the best for preserving, and to follow the others named. There are other Rhubarbs, but not being good forcers, or being paler in colour when forced, or for other reasons, I do not mention them. *G. W'ghes.*

HOME CORRESPONDENCE.

THE PEACH OUT-OF-DOORS.—Mr. Mayne, gardener, Bickton, Devon, writing under the above heading at p. 279 of the last volume of *Gardeners' Chronicle*, desires information with regard to the training of trees on walls with nails and shreds, and wire and ties. If Mr. Mayne were to refer to his *Gardeners' Chronicle* for October 30, 1895, he would see a note of mine on Peach and Nectarine trees, two of each, trained to wires—galvanised iron wires—which had received two or three coats of stone-coloured paint. These wires are fixed horizontally at 6 inches apart, being passed through galvanised iron eyes (which were also painted), standing about 1 inch from the wall, and to these the branches and shoots were tied with bast in fan form, the walls being about 12 feet high. The article in question will show that the trees and the crops which they annually bore were everything that could be desired, and had I not thought of severing my connection with Longford twelve or eighteen months earlier, I should have wired the other Peach walls, so satisfactory were the results secured from the trees in question; although, for that matter, all the Peach trees out-of-doors, as well as indoors, grew well, and here heavy crops of fine fruit annually under the treatment which they were subjected to. But the fruits obtained from the trees trained to wires were unusually free from insect disfigurement, owing to the fact of their not being close to the wall, and from the crevices of which woodlice and other troublesome creatures prey upon the side of fruit next the wall without being seen until the fruits are gathered. However, to any reader of the *Gardeners' Chronicle* who may contemplate wiring a Peach wall, I would say if the wall should be an old one, "first wash it with liquid-lime, into which a few handfuls of fresh soot has been stirred, dabbing this well into the crevices with the whitewash-brush in doing the work, and then point the joints with good mortar." I cannot see any reason why good crops of Peaches and Nectarines cannot be secured from trees occupying walls having a south, west, and even east aspect in all the southern and western counties in England, Ireland, and Wales, and in the south and west of Scotland under proper cultivation. *H. W. Ward, Lime House, Rayleigh, Essex.*

In reply to James Mayne's enquiry in a recent issue of the *Gardeners' Chronicle*, on the sub-

jeet of nailing and wiring walls, I may state that here on the walls of the East Riding of Yorkshire, Peaches grow and fruit admirably on walls that were built and wired for these trees and for Pears, &c., twenty-four years ago. The wire is of iron galvanised, and is placed periodically at 6 inches apart. I have not observed any bad results from use of this kind of wire. The trees are easily fastened to the wires, and the saving of labour compared with nailing is considerable. The walls are in condition, without nail-holes, to harbour earwigs, wood-lice, &c.; the wires are placed close to the face of the wall, the branches and shoots being tied with rafia and soft string. The earwigs start with the rafia and soft string. The walls have small heads, and are driven in close. With wire running vertically, it is easy to train a tree in any fashion. For training Morello Cherry trees, wires are very satisfactory. The lengths of wire being short, it is an easy matter to replace one when broken, or become rusted through, which is not often the case, if a wall is provided with a good coping to keep the face of the wall dry; when strong shoots press tightly on the wires we insert a cloth shrod or bit of canvas between the shoot and the wire. We use no more than one crop of Peaches, with no more protection afforded them when in flower than a double thickness of fishing-net. *Bailey Hobbs, Birdsall, York.*

CEDRUS DEODARA AND C. ATLANTICA.—More than sufficient has appeared in recent numbers of the *Gardeners' Chronicle* to show that in favourable spots the Indian Cedar, *Cedrus Deodara*, grows and thrives well, and forms a beautiful tree in this country; while ample proof has been given, if it was needed, that this valuable timber tree in Northern India is never likely to become a profitable one to plant extensively for timber in the British Isles. Its timber, so far as it has been fairly tested, is neither better nor worse than that of the Cedar of Lebanon, of which home-grown and fully matured timber has long been available for experiment. The timber of the Deodar may improve as the trees reach maturity; but no sign of any improvement has yet appeared in the timber of the oldest trees grown in this country, and tested. It was introduced in 1831, and therefore the oldest timber experimented upon has not been the produce of a "ripe" tree. On p. 59 of the last week's *Gardeners' Chronicle*, Mr. Divers gives some very interesting remarks about the Mount Atlas Cedar, *Cedrus atlantica*, at Belvoir Castle, in which he expresses his opinion that *C. Libani* and *C. atlantica* are identical, botanically. In that opinion most authorities now agree, and include the Deodara in addition—looking upon the three trees as geographical varieties of one species, although, for garden purposes it may be better for a while yet to treat them as species, each having two or more varieties. The most interesting point, however, in Mr. Divers' remarks is, where he mentions a *Cedrus atlantica* cut down in 1891, with "a girth of 8 feet 6 inches at 3 feet from the surface, a good record for ninety-six years growth," and adds, "there are many trees of it here of a similar size;" and presumes of the same age? It is recorded by our best authorities that *Cedrus atlantica* only reached Europe in 1811, and it would be of special value to clearing up the history of the tree in England, of the origin and date of introduction of the "many trees" of it growing at Belvoir Castle could be clearly explained and substantiated as occurring in the end of the last century? Tradition has it that a tree of *C. atlantica* was planted at Biel, in East Lothian, in the year 1707. Is there any record extant to prove this? Specimens with cones from Belvoir and Biel might be sent to the editor of the *Gardeners' Chronicle* for identification; and the history, as far as it can be given on good authority, of the trees at both places would be interesting reading. *D.*

RORIDULA GORGONIAS.—This remarkable Cape insectivorous plant is now flowering here for probably the first time under cultivation. The plants were raised from seed received from Kew two years ago, and are now of different heights up to 1 foot in the largest specimen. This species resembles greatly *R. dentata*, and is of an erect growth, with alternate linear leaves, bearing what appear to be two sets of tentacles, long and short, tipped with glands, the former possibly also bearing stinging glands. Although a bear ally of the *Droseras*, it differs in the tentacles, exhibiting no movement, and thus more nearly resembles the genus *Prosoplythum*. The terminal inflorescence here carries six flowers, about half an inch in diameter. The petals are white, and around the style are arranged the anthers, which are

brown, with yellowish uppermost tips; the yellow stigma being raised a little above the anthers. Like the *Droseras*, the flowers are short lived. This genus has always excited considerable interest in these gardens, where specimens of *R. dentata* were for several years to be seen, some of which were more than 5 feet in height. The illustration in the *Gardeners' Chronicle* for September 26, 1891, on one presented to Kew, well portrays the habit of these remarkable plants. Unluckily, these fine plants never flowered, and the species is, I believe, not now in the garden. The cultivation of the genus does not seem difficult when the right position is found for them, which, according to experiments made here, is a fairly moist atmosphere in a temperature a little below that kept up in our tropical stoves. The plants are by no means vigorous in rooting, and a sandy peat is the compost we use for them. *R. L. Horroon, Royal Botanic Gardens, Edinburgh.*

A CLUSTER OF APPLES.—With regard to the cluster of Apples figured on p. 27 of a recent issue of the *Gardeners' Chronicle*, Prof. Bailey, in his new work, *The Sarcoid of the Unlike*, alludes to the prevalence of a dissociation of sexes in cultivated Apple trees; and that while Apple blossoms appear in clusters of five to ten, yet rarely are more than one or two developed into Apples, although with Crabs it is often the case. This loss of progeny in orchard Apples is due to the greater vigour of the one which withdraws the nourishment to itself at the expense of the others; but the question is, why should it do so, as it is not the case with the wild tree? Mr. Bailey says:—"I am inclined to think that these extra flowers serve a very useful purpose in supplying pollen to those which chance to set, for not only is the supply of pollen in the individual flowers probably becoming less with the improvement of the Apple, but it is also probable that more is needed to incite the enormous increase in size over that of the inferior aboriginal Apple" (*Op. Cit.*, p. 352). Now this is due to the great tendency to separate the sexes in some cultivated fruit trees. This, therefore, probably accounts for the fact of one blossom which is "more female" in character developing a fruit, while the others are "more male," and so tend to fall without setting at all, or if they do, such fruits fall prematurely. The rationale, therefore appears to be, that high cultivation favours the development of the female organ—just as Mr. Meehan has shown, that in monocious trees the female flowers are on the stronger shoots—with an accompanying suppression of the female organ in other flowers, which the say does not run so directly. Hence, there results more or less degrees of infertility of particular varieties with their own pollen. It is a mistake, therefore, to plant large areas with one variety only, if such appears to be at all self-fertile. "Mixed orchards," writes Mr. Bailey, "are, as a rule, the most successful ones." With regard to the cluster of Apples from the north of Ireland, such would consequently seem to indicate a tendency to return to the conditions which obtain among wild Crabs. *George Huxford.*

WOOD-ASHES AS A MANURE.—The value of wood-ashes is not so well understood as it should be by the gardener. Some of them admit that under certain circumstances wood-ashes are useful as a manure; but it would puzzle them to afford a reason for their belief. Mr. Willis' note on the subject in a recent issue of the *Gardeners' Chronicle* contains some facts especially useful to the gardener. No finer dressing can be afforded to soil than any manure, especially those which are easily worked, and which wet weather does not render unworkable for great lengths of time. I can remember that in the garden where I served my apprenticeship we used to keep a smouldering heap in an out-of-the-way corner pretty nearly the whole year round, and the ashes from this heap were sifted from time to time, and used for top-dressing the lawns. Since then I have found out that wood-ashes can be used with advantage for various purposes, but the sifted product of the smother-heap should not be left exposed to the weather. Ornamental foliage stove plants are especially benefited by wood-ashes being mixed in the potting compost, so material that I have used giving them a better colour to the foliage. I have grown Crotons, Dracenas, Palms, Marantas, &c., with and without wood-ashes, and the contrast between those which received wood-ashes and those which did not was almost incredible. Enclaius grow luxuriantly if wood-ashes be mixed with the potting compost; Chrysanthemums, Roses, Carnations, Vines, and Tomatoes, are especially benefited by frequent top-

dressings of wood-ashes. Most gardeners know the value of wood-ashes when applied to many sorts of root-crops, and no better manure can be given to a field of Potatoes. I am of opinion that where wood-ashes are applied to an open soil, farm-yard manure must also be liberally applied. One benefit derived from wood-ashes when mixed with potting mixtures is the length of time during which the soil remains sweet; and it towards the end of the growing period a little of the surface-soil be removed, and a sprinkling of wood-ashes, together with suitable soil afforded the plant, the vigour of the plants will remain unchanged for a considerable length of time. *T. H. Smith, South Tottenham.*

PRIMULA OBOCNICA. In addition to the value attaching to this plant for blooming so freely under glass at this season of the year, must be added that the blossoms standing well in an open state, with the addition that the partly-expanded buds will open out when the flower-stems are in water. It is as fine of blossom as a double white *Primula sinensis*, and like it, it is successional as well; and the flower-stems being long, they are well adapted for home decoration in various ways. So far comparatively little variation has appeared among seedlings. The blossoms of some are larger, rounder, and stouter than others, and there is a tendency to deepen the tints of some individuals to something approaching mauve. Supposed crosses with *P. sinensis* are abundant, and perhaps it would unite with *P. Sieboldii*; at any rate, the experiment is worth making. *R. D.*

VIOLAS AS BEDDING PLANTS.—The chief value of the Viola lies in its adaptability as a bedding plant. It is also exhibited in sprays, but that is a mere incident in its development, and the practice can scarcely endure for long, and one main reason is that it has led to a number of varieties being put into cultivation because they are exhibition sorts, and quite apart from their usefulness in the flower-garden. Orders have been given for varieties seen exhibited as sprays only to be found of loose till growth, irregular in habit, spare of bloom, and disappointing of the large number of varieties now in cultivation but few are destined to be permanently grown; and of these latter sorts over ten years old still hold the field. The Royal Horticultural Society is wisely arranging a trial at Chiswick next year, as a test of adaptability for flower garden work; it is to be hoped the committee of inspection will select only those of dwarf compact habit, free and persistent in bloom, producing symmetrical rather than irregular and uneven heads of bloom; and insisting upon stout well-formed flowers of distinct colours or harmonious combinations. If they will do this they will prove benefactors to the horticultural community. When it was stated by one of the leading officials of the National Viola Society that the use of the Viola as a spring bedding plant is a barbarous practice, it was felt that the society was practically condemning one of the most useful purposes to which the Viola can be put. There is urgent need for a group of Violas of hardy character, that standing the rigours of our English winters, will bloom with the Hyacinth and the Tulip. There are a few varieties which may be termed precocious bloomers, such as Arlwell Gem, Bullion, Skyark, Blue Cloud, and Lemon Queen; and to these may be added Sweet Lavender, one of the earliest to flower on two-year-old plants. This group needs additions of yet greater precocity. Earliness of bloom is the great desideratum, and the Viola needs to be subjected to the same conditions as the late Mr. William Ingha used to carry out with his Antiochias, Wallflowers, Primroses, and other subjects at Belvoir. His favourite phrase was that he educated his plants, meaning that he selected his seed-parents because of unusual precocity in flowering, and in this way he obtained subjects to bloom in February which had hitherto not flowered until March. Some such process is needed with the Viola. As a rule, two-year-old plants will be found to bloom earlier than young ones. While unwilling to appear dogmatic, I think that plants obtained from division bloom earlier than those obtained from cuttings. Therefore I would pull the plants to pieces in September or October, and plant them out in nursery beds, and allow them to remain there one year, and then employ them for carpeting beds of bulbs to flower in the spring. Such plants would in a year make dense tufts; they would furnish the surface at once, and during mild intervals during the winter would blossom, and as soon as the weather became spring-like, proceed to flower beautifully; or, plants may be raised from cuttings in July, planted out in nursery-beds as soon as rooted, and then employed

for carpeting beds in October. They would bloom fairly early in spring, and with an occasional top-dressing or two with rich soil, bloom all through the summer. Procreancy may be furthered by selecting the earliest bloomers among the seedlings. It is usual to sow seeds in the spring, and if this be done in boxes, the seedlings need to be pricked off into other boxes as soon as large enough, or into a prepared bed in a cold frame, and planted out in showery weather in July; while something would probably depend upon the size and vigour of the plants. Such varieties which are among the earliest to bloom, if other desirable qualities are present, may be selected as evidencing precocity, and eventually prove useful in the spring garden. Any substantial additions which can be made to the select list of early-flowering Violas will be gladly welcomed by those who are leading the movement in favour of a revival of spring bedding. R. D.

CUPRESSUS MACROCARPA.—The correspondent of the *Gardeners' Chronicle*, "Experience," now contributing a valuable series of articles on the propagation of plants, and on methods of transplantation, brought to my mind, in his allusion to the recent issue of the *Gardeners' Chronicle*, the great liability of *Cupressus macrocarpa* to make large top-growth and relatively few flowers, a remarkable case in point, which could have been seen in the gardens of Howick Hall, Alnwick, some few years ago, and which may, for all that I know to the contrary, still be seen there. A small pot-grown specimen of *C. macrocarpa* was planted in the soil of the old flower-garden in the year 1856, which grew at a great rate in the deep virgin soil resting on whinstone, making 2 to 3 feet of leaved in a year, and becoming proportionately bulky—indeed, it soon became a handsome tree, although many thought rather inappropriately situated, as it stood out in front of a range of glasshouses. Its over-tum was constantly predicted by those who remarked its great bulk and apparently fragile root-hold of the soil. These predictions, so far as I know of, were not verified, its tap-roots having passed through the soil into the fissures of the whinstone, anchoring the tree most securely. In shallow soils, unless these should chance to overlie chalk, which is a substance abounding in fissures, and which many species of Conifers succeed in admirably, the tree is sure to get blown over when large, unless protected from the more boisterous quarters. If this paragraph should meet the eye of Mr. Inglis, he would perhaps tell us if this specimen of *C. macrocarpa*, planted by Mr. Moore, is still in existence at Howick. F. M.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

JANUARY 12.—*President*: Mr. Michael (in the chair); Mr. Lynch, Rev. W. Wilks, Dr. Russell, Dr. Bonavia, Mr. Douglas, and Rev. G. Henslow (Hon. Sec.).

Fimbristylis Doreana. It was reported from Ken that the specimens exhibited at the last meeting were too much decayed to be able to ascertain what fungus, if any, had caused the disease.

Senecio multicaule *Hybrids*.—Mr. Lynch exhibited a number of specimens which he had raised by crossing 8 multi-flowered with various sorts of the garden or field variety. The colours much resembled those of the latter plant, the foliage being intermediate, and the height about 3 feet. All but one had 8. multicaule as the female parent, the results showing therefore great prepotency on the part of the male (*C. maritima* 8. multicaule was first introduced from the Canaries in 1855. (*Hed. Mag.*, tab. 4904, *Botanicum Bourgeoi*).

It was subsequently lost from Kew, and reintroduced to Cambridge by Mr. Gardner in 1855. Some of the flowers showed a peculiar circular white spot on the red tip of the petals (*Gardeners' Chronicle*, Jan. 16, 1857).

Cucurbit crinita.—Mr. Douglas said that he is raising seedlings of this plant, in order to see if it varies towards the cultivated form without being crossed. Mr. Lynch observed that *C. Tussilaginis* was a species which apparently most nearly resembled the cultivated *C. crinita*.

White Narcissus, officinalis *Clavatus*.—Dr. Russell exhibited some cut flowers of white *Polyanthus* *Narcissus*, which he had placed in solutions of acid red magenta (Judson) dye, and in acid green. The colours had traversed the fibro-vascular cords, and then spread over the intermediate tissues, forming a border round the ends of the petals. The purpose investigating the matter to try and discover the general nature of these colours which will act in this way. It took from twelve to fifteen hours to infuse the perianths. Mr. Henslow remarked that John Lawrence in his book on gardening (1726), said that people in his day used to colour flowers by letting the roots lie in a solution of the lees of chert.

The Annual Report

has been issued in anticipation of the annual meeting on February 9. The Council are glad to be able to report the conclusion of a full and satisfactory year's work.

Financially, the balance in hand is not as large as it was last year, but this is more than accounted for by the extraordinary expenditure which the Council felt able to undertake at Chiswick, the whole of which has been defrayed out of income. The conservatory at the entrance to the gardens, which had for so many years required repair, has been entirely removed, and replaced by a building in every respect worthy of the Society; and the two old greenhouses, Nos. 1 and 2, which had been an eye-sore to the gardens by reason of their ruinous condition for almost a generation, have been remodelled and rebuilt. The total of this extraordinary expenditure is over £500.

Under the head of ordinary expenditure at Chiswick, £1870 has been spent on the general work and repairs and keeping up of the gardens. Amongst other work, House No. 17 has been practically rebuilt, Nos. 15 and 16 have been very thoroughly repaired; the young men's booths have also been put in good order and made more comfortable. The receipts by sale of surplus produce amount to £714, making the net ordinary cost of the gardens £1556.

The Council have every reason to congratulate themselves and the Society upon the selection which they made to fill the office of Garden Superintendent.

At Westminster, nineteen Floral and Foliage Meetings have been held in the Drill Hall, James Street, Victoria Street, and six Committee Meetings have been held at Chiswick, besides the larger Shows in the Temple Gardens, on May 19, 20 and 21; and at the Crystal Palace on October 1, 2 and 3. Lectures have been delivered at fifteen of the Meetings, exclusive of those given at the Crystal Palace. The number of awards granted by the Council, on the recommendation of the various Committees, has been as follows:—

AWARD	On the Recommendation of the					Total.
	All Provincial Shows	Scientific Committee	Floral Committee	Foliage Committee	Other Committees	
Gold Medal	1	1	3	1	—	6
Silver-gilt Flora	5	5	17	1	1	21
Silver-gilt Knightian	2	—	9	—	—	11
Silver-gilt Banksian	1	—	1	10	—	12
Silver Flora	13	—	68	34	—	115
Silver Knightian	2	—	16	—	—	18
Silver Banksian	8	—	22	78	13	112
Bronze Flora	—	—	—	7	—	7
Bronze Knightian	—	—	4	—	—	4
Bronze Banksian	—	—	5	26	5	36
First Class Certificate	4	—	8	36	36	84
Award of Merit	17	—	23	210	10	257
Botanical Certificate	1	—	2	17	—	20
Cultural Commendation	8	—	13	6	35	62
Highly Commended	10	—	—	—	—	10
Commended	3	—	—	—	—	3
Total	75	1	102	463	303	4148

The Council must again express their opinion that there still appears to be a tendency to multiply unduly the awards recommended, and they therefore request the several Committees to consider seriously whether there is not a real danger of impairing the value of these distinctions by such increase of their number; and whether it would not be possible, as well as politic, to be somewhat less generous in the recommendation of awards during the ensuing year. This is a question which the Council cannot but regard with solicitude, and they hope that every Member of the Committee will consider that he has a real and shared responsibility for the welfare of the Society in this matter.

The work of the Committees has of late increased so considerably that the delay of communication between the Council and the Committees has on several occasions caused great inconvenience. The Council, therefore, think it well to revert to an old rule of the Society, that the Chairmen of the principal Committees shall in future be chosen from among the Members of Council.

At the unanimous request of the Orchid Committee, and on certain members of it undertaking to pay a third of the expense, the Council have arranged to have paintings made of all the flowers certified by this Committee. Exhibitors must, therefore, distinctly understand, that in submitting their flowers in future to the Committee, they thereby tacitly consent to their being painted should they obtain any award, and must hold themselves ready to give reasonable facility to the Society's artist to do so. The Orchid Committee desire to have these paintings as an accurate record of the characters and peculiarities of the plants to which awards are made, finding it practically impossible for their members to bear in mind the details of numerous flowers when seen but once.

The Council desire to draw the attention of all Fellows of

the Society to the more extended use which the Scientific Committee might be to them if they availed themselves more freely of their privileges in submitting instances of injuries to or injuries caused by insects or otherwise. The Scientific Committee is composed of gentlemen qualified to give the best advice on all such subjects, either in respect to the prevention or cure of disease. The Committee is also glad to receive specimens of malformation or other subjects of Horticultural or Botanical interest.

The Council wish to express their thanks to the Director of the Royal Gardens, Kew, for allowing them to consult Mr. Messrs. F. L. S. on the subject of the new building for the Scientific Committee; and to the Director for his readiness in giving them the advantage of his knowledge and advice.

The Society's Great Show held (by the continued kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was as successful as ever, and it is a matter of satisfaction to the Council to find that this Meeting is now universally acknowledged to be the leading Horticultural exhibition of this country. The best thanks of the Society are due to all who kindly brought their plants for exhibition, or otherwise contributed to the success of this Show.

The Exhibition of British Garden Fruit held by the Society at the Crystal Palace, on October 1, 2, and 3, was, considering the season, eminently satisfactory to all gentlemen who will be found in Vol. XX, Part 2, of the *Journal*, issued in December.

As an object lesson in British Fruit cultivation this Annual Show stands unrivalled, and is of national importance. The Council invite Fellows and other gentlemen to support it, but cannot be too widely known that the continuance of the Show by year is absolutely dependent on at least £100 being raised by subscription each year towards the Prize Fund. The Show involves the Council in a very large expenditure without the possibility of any return. They have therefore established the rule that they will not continue it unless sufficient interest in it is taken by Fellows and their friends to raise £100 towards the Prize Fund. Subscriptions for this purpose should be sent at once to the Secretary, 117, Victoria Street, Westminster, and if the list prove satisfactory the Secretary will send a circular to the effect that the Show will be held on September 30 and October 1 and 2, 1897. The list of subscribers for 1896 will be found on page 129 of Vol. XX, Part 2, of the Society's *Journal*.

Deputations were sent by the Council at the invitation of the local authorities to attend the great horticultural gatherings at York in June, and Chester in August, 1896. Full particulars of these visits will be found in the Society's *Journal*, Vol. XX, Part 1, p. 27, and Vol. XX, Part 2, p. 130. The Council cannot, however, refrain from taking this opportunity of congratulating York and Chester on the admirable displays of Horticulture and the enterprising spirit at their respective fairs and gales, and of recording the very great pleasure which these visits gave, and their appreciation of the great courtesy and hospitality with which they were received in both cities.

The *Journal* of the Society has been continued so as to enable Fellows at a distance to enter more fully into and reap the benefits of the study and work of those actively engaged at headquarters. Vol. XIX, Part 3, and Parts 1 and 2 of Vol. XX, were issued during the year, and Vol. XX, Part 3, is now almost ready for issue.

In January, 1893, the Council published a list of all Plants, Flowers, Fruits, and Vegetables certified from the year 1870 to 1892. A Supplement is now ready, bringing the list down to December, 1896. Each part is issued at the price of one Shilling, but the two together may be obtained for Eighteenpence, at the Society's Office.

An examination in the principles and practice of Horticulture was held on May 1, concurrently in different parts of the United Kingdom, a centre being established wherever a magistrate, or clergyman, or schoolmaster, or other responsible person accustomed to examine work, consented to act in connection with the Society's behalf, and in accordance with the rules laid down for its conduct. No limit as to age, position, or previous training of the candidates was imposed, and the examination was open to both sexes. 173 candidates presented themselves for examination. The answers and solutions of those who succeeded in satisfying the examiners, together with the number of marks assigned to each, will be found in the Society's *Journal*, Vol. XX, Part 1, 1896, page 58.

It is proposed to hold a similar examination in 1897, but at the request of those most nearly concerned, the date has been altered from the 1st of May to the 1st of June, and the examinations held at the beginning of May by the Science and Art Department, candidates wishing to sit for the examination should make application during February to the Secretary, R. H. Esch, 117, Victoria Street, Westminster.

The Council have, with much pleasure, that Mr. N. Sherwood, Esq., Master of the Worshipful Company of Gardeners, was most kindly offered, in connection with the Society's 1897 examination, a Scholarship of £25 a year for two years; full particulars of which will be found in the Society's Arrangements for 1897, lately issued to all Fellows. Another similar offer has been made by Mr. G. W. Burrows, Esq., a Member of the Court of the same Worshipful Company.

Acting in conjunction with the Lindley Trustees, the Council have devoted considerable attention to the Library. All serial publications have been kept up to date, a large number of new books have been purchased, and the following new books, amongst others, added to the Library,

viz.: "The Student's Handbook of British Mosses," "Les Végétales Américaines," "Useful Plants of Japan," "Orchids of South Africa," "Scott's Flowerless Plants," &c. &c.

A sum of £125 has been received for the Catalogue Fund, which was started in 1894, and the proof sheets of the Catalogue now in the hands of the printer.

The hearty thanks of the Society are due to all the Members of the Standing Committees—viz., the Scientific, the Fruit and Vegetable, the Floral, the Orchard, and the Narcissus Committees, for the kind and patient attention which they have severally given to their departments. The members of the Staff of the Society are also due to all those who, either at home or abroad, have so kindly presented books to the Library, or plants or seeds to the Gardens. A list of the donors has been prepared, and will be found in the Society's Journal, Vol. XX., Part 3, 1897, now almost ready for issue. Where so many have been generous it almost appears invidious to mention any by name, yet the Council think it only their duty on behalf of the Fellows to publicly thank the principal donors, amongst whom have been Messrs. George Bunyard & Co., of Maidstone; Mr. John Fraser, of Woodford; Messrs. Lew & Son, of Hammersmith; Messrs. Paul & Son, of Clonshatt; Messrs. J. R. Pearson & Sons, of Chilwell; Messrs. T. Rivers & Son, of Sawbridgeworth; and Messrs. James Veitch & Sons, of Chelsea.

The Council wish to express, in their own names and in that of the Fellows of the Society, their great indebtedness to all who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of the fortnightly Meetings in the Drill Hall. They are glad to find by the increased and increasing number of visitors that the Society's fortnightly Meetings are at last becoming appreciated by the Fellows and Public in general. In their judgment the shows which take place at short intervals throughout the year, furnish horticultural displays and teach horticultural lessons which cannot be obtained elsewhere in the kingdom.

The Council have the sad duty of recording the death of 22 Fellows during the year, and among them they regret to find the names of Baron Sir Ferdinand von Keller, one of the most staunch and energetic supporters of the Society in Australia, Dr. Trimen, Bruce Findlay, Richard Boxam, Henry Schotham, T. A. Cledstones, Anthony Waterer, the Earl of Darley, Sir Joseph Prestwich, Lord Sverdrup, Robert Warner, Sir Julian Goldsmid, George Prince, and Marianne Lysons.

The following Table will show the Society's progress in regard to numerical strength during the past year:—

DEATHS IN 1896.		FELLOWS ELECTED 1896.

A scheme for the affiliation of Local Horticultural Societies was put forward in 1896, and 83 Local Societies have availed themselves of it. The Council express the hope that Fellows will promote the affiliation of Local Horticultural and Cottage Garden Societies in their own immediate neighbourhood.

As the result of some of the Fellows, the Council have arranged to send a reminder of every show in the work preceding it, to any Fellow who will send to the R. H. S. Office, 117, Victoria Street, Westminster, 22 Halfpenny Post Office, fully addressed to himself, or to whomsoever he wishes the reminder sent.

The Council recommend that the salaries of the principal officers of the Society, the Secretary, the Assistant Secretary, the Superintendent, and the Assistant Superintendent should continue as at present.

The Council have had before them various proposals for celebrating the attainment by Her Most Gracious Majesty the Queen, Patron of the Society, of the longest reign in English history. Some of these proposals were for various reasons or for other reasons to be impracticable, others were found to involve a far larger expenditure of money than the Society can command or could reasonably hope in so short a period to collect. They have therefore, after most careful consideration, decided, with Her Majesty's gracious permission (see letter on p. 69 of the present issue), to strike a special medal or medallion, to be called the "Victoria Medal of Horticulture," and to be awarded *honoris causa* in the domain of Horticulture. They will also (if) join in the celebration of the event which is to take place at the Great Show to be held at Shrewsbury in August, to which they have received very cordial invitation.

The Council, in closing their Report, desire most respect-

fully to tender to Her Majesty their most sincere and thankful congratulations on the approaching completion of the reign of Her Majesty Queen Victoria, and to assure her that they are confident that every Fellow of the Society will join with them in saying "God save the Queen."

EDINBURGH BOTANICAL.

JANUARY 14.—The monthly meeting of the above society was held at 5, St. Andrew Square, Edinburgh, on Thursday evening last, at 8 o'clock, Dr. A. P. AIRKEN in the chair.

MR. AIRKEN.—After the reading of the "report of the proceedings of the Council," the public business was proceeded with. The most important communication upon the billot was from Professor WILLIAM SORBUSVILLE, of the Durham College of Science, entitled "Experiments with Nitragin." After pointing out the various developments of the nitragin question during the past few years, and giving a slight review of the work of Professor SORBUS and Tharand, and Dr. HICNER in the patenting of these bacteria known as "nitragin," and sold at M. 2.75 per bottle, by Meister Lucius and Brunina's successors at Hockstadt Mainz, this being sufficient quantity wherever it to dress one morgen of land for the year, or to give a slight increase in the yield of experiments carried out in a garden attached to the college.

These experiments were pointed out as being carried on in duplicate, the proper methods being used to inoculate the soils. In the case of the first-mentioned experiment with Peas, 1 pint (Dickson's First and Best), the use of nitragin had apparently increased the yield 6 per cent. over the not inoculated plots. In the second, namely, one with Broad Beans, two-thirds of a pint (Early London Pod), a loss was shown when nitragin was used. The loss by inoculation being 1 1/2 per cent. Thus showing an increase of weight in the not inoculated plot.

In the experiment with Lucerne and Broad Red Clover, the plots were not duplicated. The produce being weighed green immediately after cutting. In neither case did the nitragin benefit the plants. The uninoculated produce being heavier by 24 per cent. in the case of the Lucerne, and in the case of the Clover 88 per cent. than that grown upon inoculated ground. Three ounces of seed were employed for 1 r each plot of Lucerne, and 1 1/2 oz. for each Clover plot. In the cases of Red Clover and Lucerne it was stated that neither had ever been cultivated in the gardens, the condition, therefore, being distinctly favourable for the experiment. The loss upon the plots upon the plants. As Peas and Beans had been cultivated during recent years in the garden, it was stated that it was not surprising that the application of a pure culture of these bacteria should have been unproductive. The paper was freely discussed by the members, and among others, by Professor J. P. BALFOUR, who in answer to a question asked by the corrector of the term bacteria, spoke of the word "bacterioides," being the better fitted to express correctly these cultures.

MR. A. D. RICHARDSON gave the following notes of the *antecedent* record taken at the Botanic Garden during the year 1896:—Barometer at 10 a.m. on 22 days, mean, 29.74 inches, on the 20th; lowest, 28.86 inches, at 9 a.m. on the 5th; mean, 29.57 inches. Shade thermometer: highest, 56.25° on the 26th; lowest, 26.95° on the 1st; mean, 39.57°.

Frost occurred on ten days. Radiation thermometer: highest in sun, 87.2° on the 20th; lowest on grass, 18.96° on the 21st; in shade, 65.00° on the 22d; on 22 days, mean, 60.3° sunshining for total, 107 hours. Snowless days, 21. Rainfall: total for month, 3.45 inches. The greatest fall occurred on the 4th, 0.500 inches. Rainy days, 23.

A review of notes for 1894-5 showed the mean barometer reading to be 29.850 inches. The highest thermometer reading, 74.8° on May 11; lowest, 22.8° on January 25; mean, 48.2°. Total sunshine for 1896 was 1069.7 hours, being 133.3 hours less than 1895. Total rainfall, 23.75 inches. A communication was read by Mr. Richardson which had been received by Professor Balfour from Professor Koehne, on some notes of the collection Aria of the genus Pyrus (which we give at the end of this report, &c.). Mr. L. F. HARRIS read his "Notes on Plants in Plant Houses of the Royal Botanic Gardens, Edinburgh," and exhibited *Roridula goniatica* in flower.

Hybrid Forms of Pyrus.—Professor Koehne's observations upon the genus *Pyrus* are now being collected at G. M. Landsborough of Kilmarieck, in Arran, last year (which were transmitted by Professor Balfour to Professor Conwentz of Dantzig, an authority on the genus), and also on specimens collected by Mr. Augustin Ley in Breconshire. The result of the sorting to Professor Koehne, the sole of the forms he received by him from Breconshire and Arran, belong to two species, viz., 1. *Aria suecica*, Koehne (*Crataegus Aria var. suecica*, Linn.; *Pyrus intermedia*, Ehrh.; *Sorbus scandica*, Friess; *Pyrus decipiens*, Bechst.; *Aria scandica*, Deene.; *Pyrus scandica*, Bähning), and 2. *Sorbus aucuparia*, Linn. (*Pyrus aucuparia*, Gort.).

Of the two specimens mentioned by Professor Koehne as having been received from Breconshire, one (collected from a limestone cliff near Methery Tyddil by Mr. Ley on May 28, 1895), he believes to be the typical *Aria suecica*, Koehne; while the other he considers to be a hybrid between that form and *Sorbus aucuparia*, Linn. and which he considers to be the former. All the Arran plants of which specimens were received by Professor Koehne, he declares to be hybrids. Two from Glen Catacol he considers to be the typical hybrid *Aria suecica* x *Sorbus aucuparia* (*Crataegus Aria var. fennica*, Linn.; *Sorbus aucuparia*, Linn. and W. Koch.; *Sorbus fennica*, C. Koch.) while all the others he considers to be intermediate forms between this and *A. suecica*.

It would, therefore, appear that *A. suecica*, Koehne, had not been collected in Arran by Dr. Landsborough; and as Professor Conwentz, when he visited the Royal Botanic Garden, Edinburgh, last year did not find that species in the Herbarium collection, there seems to be some doubt as to its occurrence in Arran, especially as the collection contains a considerable number of specimens of what are supposed to be that species from various parts of the island.

Professor Koehne further remarks that he is persuaded that if careful search be made, intermediate forms between the typical hybrid and *S. aucuparia* will be found, and he states that these forms "are scarcely to be distinguished from *Sorbus aucuparia*, since they have completely pinnate leaves, in which, however, the upper leaflets are a little decurrent on the midrib of the compound leaf, or are slightly fused together." A. D. R.

SOME OBSERVATIONS ON UREDINEÆ.

In a previous article (*Gardeners' Chronicle*, vol. vii., p. 773), it was shown that *Puccinia bistorte* is heterocyclic in character, and that the common earth-nut (*Conopodium denudatum*) serves as host-plant for the aecidiospores. During the spring months of the past year, close attention was again devoted to the study of this uredine, and a quantity of leaves of *Polygonum bistorta* bearing the teleutospores were over-wintered for this purpose. As a rule, it is not easy at the close of winter to find a trace of the teleutospores, at that time the leaves of the host being completely decayed. Last winter, however, was exceptionally mild, and during February and March fragments of bistort leaves dotted with sori of teleutospores were readily to be found, and early in March these were observed to be in an active state of germination. By the end of March aecidiospores were unusually abundant on the leaves of the earth-nut.

In various works *Polygonum viviparum* is also given as a host for this uredine, but in previous cultures, while the aecidiospores readily produced uredospores on *Polygonum bistorta*, the result always ended in failure on *Polygonum viviparum*. From this I was inclined to think that two species had been confused, more especially when Dr. H. O. Juel described (*Mjohol. Beil. iv., Öfversigt, &c.*, 1895, p. 373) the life history of a *Puccinia* which has its teleutospores on *Polygonum viviparum*.

With a view to repeating the experiments, care was taken to thoroughly establish in my garden a number of plants of both species of *Polygonum*, together with *Conopodium denudatum*, which at the end of March were in a healthy, thriving condition.

The over-wintered teleutospores were examined microscopically many times during March, but no signs of germination were noticed, and the following cultures were made with freshly-gathered material.

On March 22 a copious supply of germinating teleutospores were applied to the leaves of several plants of *Conopodium denudatum*, with the result that on March 31, whitish, slightly swollen spots were apparent on the upper surface of several leaves. On April 8 the aecidium cups had burst through the cuticle, and on April 11 some of the aecidiospores were ripe.

On April 13, germinating aecidiospores artificially produced) were applied to *Polygonum bistorta* and *P. viviparum*, and produced uredospores on the former on April 26, succeeded by teleutospores on May 6, while on *Polygonum viviparum* uredospores were abundant on April 28, and teleutospores evident on May 9. The leaves of the latter were now more discoloured on the upper surface than those of *P. bistorta*. Ripe uredospores, produced as above on *Polygonum viviparum*, were applied on May 18 to the leaves of *P. bistorta*, and produced teleutospores on May 31. The experiments were repeated several times, with precisely the same results.

The only reason that can be assigned for not producing any result on *Polygonum viviparum* in former cultures is that the plants were not sufficiently well established, some difficulty being experienced in obtaining plants when they were required, but the above briefly-stated results are convincing that *Puccinia bistorta* has its uredospores and teleutospores on both species of *Polygonum*. On April 12, over-wintered teleutospores on *Polygonum bistorta* germinated finely, and a number of leaves contain-

ing the fungus were taken to a field and fixed near several plants of Conopodium denudatum. On visiting the plants on May 7, scoliospores were found to be fully developed.

The writer will be glad to supply material to any mycologist interested in this species.

During the Christmas holidays of 1895, while in the Lake district, teleutospores of a Puccinia were collected on one of the larger sedges—probably Carex acuta (on the margin of Lake Windermere, and near a large Gooseberry bush, the leaves of which hitherto had been abundantly invaded by Aecidium grossulariae).

One half the material was forwarded to Dr. H. Klebahn, of Hamburg, and the remainder retained for my own experiments. The teleutospores were actively germinating on April 16, and on that date applied to Urtica dioica and Ribes grossularia, but no result ensued in either case, and the experiment was repeated on May 7, but again with no effect. Dr. Klebahn, however, proved the fungus to be Puccinia Pringsheimiana, Kleb., and writes that "in two cultures 29.4.15/5 and 8.5-21/5, it produced Aecidia on Ribes grossularia, while Urtica dioica remained free." The teleutospores of this species have hitherto not been detected in Britain, and doubtless have been confounded with P. caricis, Schum. I hope to repeat the experiment, and to have the host plants thoroughly established for the purpose. H. T. Sappitt, Halifax, Yorks.

MARKETS.

COVENT GARDEN, JANUARY 21.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal submarkets, who receive the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they will fluctuate, not only from day to day, but often several times in the day.]

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table listing prices for various plants in pots, including Adiantum, Aspidistra, Cyclamen, and others, with prices per dozen.

CUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table listing prices for cut flowers, including Anemone, Arums, Carnations, and others, with prices per bunch or dozen.

ORCHID-BLOOM IN VARIETY.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table listing prices for various fruits, including Apples, Grapes, and others, with prices per bushel or ton.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table listing prices for various vegetables, including Artichokes, Beans, Cauliflowers, and others, with prices per bushel or ton.

POTATOES.

The cold weather may influence a better demand, but owing to the large stocks on hand, no advance in price is anticipated.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Large table showing weather data including temperature, rainfall, and bright sun for various days in January 1897.

The districts indicated by number in the first column are the following: 0, Scotland; 1, Scotland; 2, England; 3, England; 4, Midland Counties; 5, England; 6, Scotland; 7, England; 8, England; 9, Ireland; 10, Ireland.

NOTICES TO CORRESPONDENTS.

ADIANTUM: Ferns. Your practice of sprinkling the Ferns ought to be discontinued, and other means adopted for keeping the fronds, or rather the air surrounding the plants, humid. Sprinkle the paths, stages, sides of the pots, several times daily, (but never the hot-water pipes), and more often in summer than at other seasons; and in affording water, first let the plants get moderately dry, and then apply as much water as will moisten the soil throughout. The application of a very mild liquid-manure is helpful during growth. The constant application of driplets of water is certain to bring the soil into a soured condition, and render the plants unhealthy. Adiantum succeeds best in low, span-roofed houses running north and south, or in lean-to's facing the north provided with earthen beds on which to stand the plants, and gravel paths and floor; and if a wide shallow tank can be built in each house and left uncovered, much will have been done to render the surroundings suited to the plants.

Books: T. T. An Introduction to Structural Botany, by Dr. D. H. Scott (London, Adam and Charles Black).

CHRYSANTHEMUMS: A. P. Madame Carnot and its yellow sport C. J. Warren; International, Vivand Motel, Chas. Davis, Mutual Friend, M. Pankoucke, Chas. Shrimpton, Phoebus, Mlle. M. A. de Galbert, Col. W. B. Smith, M. Cheon de Lechâ, Reine d'Angleterre, Jno. Shrimpton, Baron de Buffères, Ed. Molyneux, Edith Tabar, and Mlle. Thérèse Rey. The above will constitute a first-class collection of eighteen Japanese varieties for exhibition purposes. There are several very fine ones that are being distributed this season, including Calvat's Australian Gold, &c.; but the usefulness of most of these for the purpose you mention has yet to be proved. Of incurveds, you might include Queen of England, Empress of India, Golden Empress of India, Lord Alcester, Mrs. R. C. Kingstom, Baron Hirsch, C. H. Curtis, Mrs. S. Coleman, Princess of Wales, Prince Alfred, M. R. Bahuant, Jno. Doughty, Brookleigh Gem, Madame Darrier, Major Bonaffon, Princess Teck, Mons. F. Mistral, and Violet Tomlin.

EOCHARIS: T. G. Yes; the common Eucharis or bulb-nite in quantity.

GARDENIA CANKER: J. H. H. We had to examine and report upon this canker some two years ago, and were unable then, as now, to indicate either cause or cure. No fungus is associated with it, except as a saprophyte on the dead spots. We had thought that the corky thickening of the bark was to be altered by change of soil, but this has now been tried—without effect. M. C. C.

NAMES OF FRUITS: H. H. Letter received, but no fruits.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as consult the following number.—Bussat, Yacucium Mortinia (Andes of Ecuador)—W. J. J., Pentille, Pittosporum tenuifolium. C. B. Cannes, Salvia leucantha—P. H. 1, Not recognised, 2, Nepenthes x Stewarti, a hybrid of American origin.

POTATO, SUTTON'S MAGNUM BONTUM: H. T. This variety was raised by the late Mr. Clarke, and introduced by the firm of Messrs. Sutton & Sons, Reading.

SALIX VITELLINA: H. G. H. The unripe tips of the shoot would be liable to injury from hard frosts, and also from wind whipping. The first kind of injury would occur in any kind of soil; and plantations of Willow not exposed to the south would be more liable than those that are thus exposed.

SCHIBERTIA GRAVEOLENS: Constant Reader. This plant is now put under Physianthus graveolens. We are unaware if it has produced seed in this country.

STEPHANOTIS FLOREBUNDA: Constant Reader. If you train out the annual growths (the stronger) before they become entangled, at 8 to 10 inches apart, and then get them well ripened, they will flower abundantly along the greater part of their growth. This applies more particularly to young plants, which have not made much firm woody shoots. Older plants that have filled their allotted space, should have some old shoots not producing much bloom removed in part, and stout young shoots laid in to replace it. Usually, short lateral shoots spring from much of the old wood, which bloom freely towards their base, and may have the tips pinched off; and the weaker laterals not being likely to bloom, should be cut-back, so as to form flowering-spurs of from 2 to 3 inches in length. The main points are to get well-ripened shoots, and thin out or spur-back from time to time all healthy growths, and train thinly on a trellis, placed within 3 inches of the roof of a stove. Do not prune till growth has begun.

DEATH.—At Aberdeen, on January 10, THOMAS DARLING, Nurseryman (Cardno & Darling), in the eighty-fourth year of his age.

THE

Gardeners' Chronicle.

SATURDAY, JANUARY 30, 1897.

THE SURVIVAL OF THE UNLIKE.*

THIS volume is a collection of evolution essays suggested by the study of domestic plants. Part I. contains nine "essays touching the general fact and philosophy of evolution; fifteen essays "expound the fact and causes of variation," constituting Part II.; while, Part III. contains the remaining six "essays tracing the evolution of particular types of plants."

The author's motive, he tells us, "is the emphasis which is placed upon unlikenesses, and of their survival because they are unlike." He denies that "organic matter was originally endowed with the power of reproducing all its corporeal attributes, or that like produced like. . . . Heredity is an acquired force, and normally and originally unlike produces unlike."

Mr. Bailey apparently draws the above conclusion from the extraordinary instability observable under cultivation, in which the permanency of racial characters is so difficult, if not impossible to acquire, as in Tomatos; but while race after race may appear and "run out," yet the Tomato, as a garden fruit, is perfectly fixed and hereditary. Similarly, there may be any number of races derived from Beta maritima, but the Beet and the Wurtzel are fixed types by heredity, however numerous may be their races. It would seem necessary to emphasize this, as the heredity of acquired characters in plants has been called in question because races are so unstable.

When, however, we turn to Nature, then the opposite view at first forces itself upon the attention, viz., a constancy and fixity of characters by heredity, constituting strongly-marked specific distinctions. It was probably this which gave rise to the idea that species were absolute entities in Nature, originally created as they are now, as might be well illustrated by Brassica oleracea, which has few or no varieties in Nature; but they are almost innumerable under cultivation. If we knew nothing of garden productions, that "mutability as a law of Nature" would never have been suggested. That no true variety will arise if the environment be constant, is a belief based on a large amount of observation; but that new variations only arise in consequence of "changed conditions of life," as Darwin and Wallace call them, is accepted, I suppose, by all evolutionists in Europe. Indeed, those essays abundantly corroborate this belief.

In adopting the phrase, "the survival of the fittest," he would define them as the "unlike,"

"In Nature, perfect adaptation is the end; she knows nothing *per se* as species or as fixed types. Hence there are as many species as there are unlike conditions in physical or environmental Nature."

This is all profoundly true, but our author seems a little inclined to forget that constant environments do exist, and that species subjected to them show no inclination to vary, as *Salix polaris*, since the glacial epoch; and the flowers of the garlands in the ancient Egyptian tombs are the same as to-day. Under horticulture, however, the reverse conditions prevail, and unlikenesses become the rule, and, thanks to this, new races are born every day.

To say, therefore, that "unlikenesses survive because they are unlike," is to transpose the cause and effect. Unlikeness to a parent is correlated with a better adaptation to the new environment, and is a result of the responsive power of the living protoplasm to the direct action of the surroundings. If a plant can adapt itself to changed conditions of life without varying, it evidently does not survive because of its likeness. Thus, *Oxalis cornua*, originally introduced into Malta from the Cape in 1806, is now spread over the whole of the Mediterranean regions on both sides of the sea from east to west, but has never changed in the least degree in its form.

When, however, Mr. Bailey appeals to facts, he arrives at the following and correct conclusion:—"I believe that the greater part of the present differences in organisms are the result directly and indirectly of external stimuli." And, therefore, mutability depends upon environment.

He suggests the following three causes of variation:—(1), External stimuli; (2), Inherent acquired energy (as seen in sports, primarily due to cultivation); and (3), sexual intermixing.

With regard to natural selection, he observes, "It has been the great misfortune of the interpretation of Darwin's writings, that his hypothesis of natural selection has so completely overtopped everything else in the reader's mind, that other important matters have been overlooked" This is very true; but it is admitted by Darwinians that natural selection is probably incapable of proof. Why such should be the case, if it be true, is a mystery. The present work is really a strong contribution to the anti-Darwinian literature from the horticultural point of view; for, although the author admits natural selection, he shows conclusively that it is a quite unnecessary factor in the origin of cultivated varieties and races. The author would see some exceptions to the rule, "that differences arise as the result of variations in the environment," such as the loss of floral reproduction when the vegetative system is in excess, as in Potatos and other plants propagated by bulbs, &c.; but this is really no exception. It is only a secondary or indirect result of the environment, for the latter is the cause of the large-sized tuber, and the principle of enlargement then follows—just as the enlarged corollas of the ray-flowers of the Corn-flower are neuter. So, too, if high cultivation be withdrawn, the plant reverts. The author accepts panmixia as the explanation; but surely, it is simply a deteriorated environment which brings about a deteriorated tuber, just as a rich soil enlarges it. "Weismann," he says, "attributes the greater number of those varieties which are usually attributed to the direct influence of external conditions of life, to be

attributed to panmixia." Why so? Why assume a non-proven hypothetical cause when the environment alone is amply sufficient?

As the author in the preface would regard his observations on bud-variation as his chief contribution to positive science, we will pass on to consider what he has to say on this subject. As a plant is a composite being, in that every part may be able to reproduce the whole, so every part can vary independently and give rise to sports or bud-variations, which arise as local adaptations on the plant. Just as seedlings are more variable under cultivation, so is bud-variation. Carrière in 1865 mentioned 154 named examples which Darwin recognised to be like seed variations "as being the direct result of the conditions of life to which the plant has been exposed." Mr. Bailey has paid great attention to the phenomena of bud-variation, and shows how varieties can and do frequently arise by it, quite irrespective of sexual processes.

Thus some seed varieties will not necessarily come true by cuttings, as the Tomato, and a long discussion is given of the large amount of variation which has arisen in the New Town Pippin,* which first arose in New York State, but has been widely dispersed by grafting; and different States have developed different forms of this Apple, respectively. "Still another proof of the similarity of bud-varieties and seed-varieties is the fact that the seeds of bud-varieties are quite as likely to reproduce the variety as the seeds of seed-varieties are to reproduce their parents." Thus, the Moss Rose reappears in seedlings, and can be transmitted by crossing. Of a peculiar Tomato, the author found that, "while most of the seeds 'came true,' but few of the second cuttings did, and, moreover, they 'sported' into several very unlike forms," with both red and yellow fruits.

As further illustrations of asexual variation among plants which bear no seeds, may be mentioned the Pineapple, Banana, and Bread-fruit, the Weeping Willow, seedless "top" Onion, and also the root of the Horseradish, and of the Jerusalem Artichoke; while those of Agarics have arisen of which not one has any sexes at all. A sexual variation is sometimes very rapid. Thus, "within two years the Chilian Strawberry varied from its wild type so as to be indistinguishable from the common garden Strawberry, which many botanists regard as specifically distinct from the Chilian." "Such a case directly refutes Weismann's hypothesis, "that all permanent or progressive variation is the result of sexual union."

This leads the author to show that true species are evolved under cultivation, in that many garden forms, as of the Tomato, Phaseolus, &c., differ among themselves quite as much or more than wild species do; and it may be as well to add that the old idea that species would not cross, is refuted every day; so that the idea of species rests now solely on form. Mr. Bailey very rightly observes that—"Species-making for ever enforces the idea of the distinctness and immutability of organic forms, but study of organisms themselves for ever enforces an opposite conception. . . . A new species, therefore, is made simply for convenience sake—hence systematic botanists look askance at horticulture. Asa Gray declared that the modern garden-Roses are "too much mixed by crossing, and changed by variation, to be subjects of botanical study." Considering

* A notice of this essay was contributed to the *Gardeners' Chronicle*, October 1, 1896, p. 31.

* By L. H. Bailey (New York: The Macmillan Co., 1896).

that we cannot certainly identify the original species of the Peach, Plum, Orange, Lemon, Wine-Grape, Sweet Potato, Indian Corn, Melon, Bean, Pumpkin, Wheat, &c., it is immaterial whether they are called species or varieties—they are new forms. . . . The horticulturist is one of the very few men whose distinct business and profession is evolution. He, of all other men, has the experimental proof that species come and go." *George Henslow*.

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

CLEISOSTOMA ZOLLINGERIANUM, Krzl.*

A VERY curious plant of Vanda-like habit, but with very short spikes of only a single flower, and few empty bracts rising from the sheaths of fallen leaves in the basal part of the stem. The flowers are about 2.5 cm. in diameter, and resemble in colour a little to those of *Saccolabium bellatulum*. The sepals are narrow-oblong, the petals linear and spatulate to the top; the colour is a very bright yellow, with two or three broad bands of mauve-purple. The lip has two straight diverging linear side-lobes, the tops of which are blunt and a little emarginated, whilst the middle lobe is triangular and curved backwards and downwards. In the disk is a thick cushion of long golden-yellow hairs; the basal part between the side-lobes, the mouth of the short spur, and the characteristic lamella or plate on the base of the column are covered with dense but shorter hairs. The spur is very short and saecate. The column is also very short.

As said before, the flower resembles in general a small flower of *Saccolabium bellatulum*, still it is a true *Cleisostoma*. Species of this genus are not very frequent in cultivation, except in botanical gardens, where they are cultivated from scientific points of view.

The next allied species with which I am acquainted is *Cleisostoma Dawsonianum*, Rehb. f., described in the *Gardeners' Chronicle*, 1888, p. 815; but the lip of this species is five-lobed, and the column has two arms ending in pencil-shaped hairs. Except these two characters, which are of the highest systematical value, the whole of both plants seems to be nearly the same; especially the brush-like or cushion-like hairs of the middle lobe, and the rounded plate on the base of the column are undoubtedly very similar. I am indebted to Mr. Zollinger-Jenny, of Zurich, Switzerland, for living material and a sketch of the original plant. It is not the first time I have the pleasure to mention the name of this gentleman. I have received from him on several occasions rare plants, imported all from the same area in the far east. *F. Krausslin*.

AGLAONEMA OBLONGIFOLIUM, Schott, var. CURTISII, N. E. Br. (new var.).

A handsome form of *Aglaonema oblongifolium*, perhaps better known as *A. nitidum*, has lately flowered with Messrs. J. Veitch & Sons, to whom it was sent from Penang by Mr. C. Curtis. As with the other species of the genus, it is not the flowers, but the well-marked variegation of its foliage, that make it an attractive plant to the horticulturist. In size shape of foliage, and in the inflorescence, it does not differ in any way from the ordinary dark glossy-green form of *A. oblongifolium*; but the leaves, which have petioles 3 to 9 inches long, and oblong acute blades 4½ to 14 inches long, by 1½ to 4 inches in

* *Cleisostoma Zollingerianum*, Krzl.—Caulis valido sub-compresso ad 40 cm. alto; foliis distichis oblongis apice bilobis lacin. longis, 3.5 cm. latis; racemis in inferiore parte caulis e vaginis nascentibus, brevibus nudioribus (f. bracteis minutis triangularibus sepalis ovatis unguiculatis obtusis; petalis sub-pilosis linearibus supra spatulatis; labelli lobis lateralis cum intermedio cuneatis linearibus apice reflexis marginatis interioribus triangulo-recurvis apice auriculatis breviterque, palmari lobis pilosis in disco infra et apice glabro, fance et lamella fovea rotundata pilosis, caldari alio ovato saecato; gynoecio minus truncato. Sepala petalorum 1.2 cm. longa, sepala 3 mm., petala 5.2 mm. lata, lobus lateralis purpureo-rufo, lobus interior pallide lateralis, pilosus et palmariis area. Inseti: Sandeher.

breadth, are most distinctly and prettily variegated with white along the course of the principal lateral veins.

It is hoped that this variegation will prove to be permanent, for it is rather effective. But in 1885, a plant at Kow, that was also sent from Penang by Mr. Curtis, had one leaf near the basal part of the stem variegated exactly in the same way as Messrs. Veitch & Son's plant, and all the other leaves on the plant were of the usual deep glossy green of the typical form. *N. E. Brown*.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM INSIGNE SANDERÆ.

IN your issue of November 28 last, p. 657, "J. H. T." replying to "J. A." says that there was only one plant originally of *Cypridium insigne Sanderæ*, part going to Baron Schroder, and the other part to Mr. Measures, both pieces flowering alike. How then comes it that Mr. Ball, Wilmslow, has a plant named C. *Sanderæ* which is quite different in shape and colour to the original one? Also, that Mr. Fred Hardy, Tyntesfield, has another named

LELIA ALBIDA STOBARTIANA.

Under this name the late Professor Reichenbach evidently intended to place all the varieties with the same characteristic orange colouring, for in the original description of the type, in which he refers to other specimens of it, *Gardeners' Chronicle*, vii., 1877, p. 271, he says, "This is a very pretty novelty, sometimes with very large flowers." This week specimens of it have been received from W. C. Walker, Esq., Winchmore Hill, and H. Cary Batten, Esq., Abbots Leigh, Bristol. The flowers are large for the species; white, with the tips of the sepals and petals coloured rose-purple for about one-third of their length, and the front lobe of the lip of a rather darker rose-purple with an orange keel in the centre. It is a pretty variety of a very useful winter-flowering species.

LUDDEMANNIA LEHMANNI.

In describing this very striking and showy Orchid, Reichenbach designated it "a fresh member of the mysterious genus *Luddemannia*," and until recently but little was known of the plant. For some time past it has been in flower in the collection of R. I. Measures, Esq., Cambridge Lodge, Camberwell (gr., Mr. H. J. Chapman). The large pseudobulbs

FIG. 18.—SPECIMENS OF CRESTED CYCLAMENS. (SEE PP. 70, 81.)

Sanderæ, which differs from both the above? Both these varieties must be spurious, since they are not C. *Sanderæ*; but, at any rate, the one Mr. Ball has is really a very fine flower, and much superior to Mr. Hardy's in point of size and colour. Orchidists seem to have a curious way of sometimes multiplying names for the same variety, and also of reversing this process by having several varieties under the same name. S. S. (The statement of "J. H. T." referred to above, is quite correct. There are not two varieties of C. *insigne Sanderæ*, though possibly the allied, but inferior, C. *insigne Sanderianum*, and other similarly inferior varieties, may have got confounded with it in some gardens. Ed.]

CYPRIPEDIUM CALLOSUM SANDERÆ.

Not until Norman C. Cookson, Esq., of Oakwood, Wylam, in a letter dated January 18, conveyed the information—"So far I have no seedling *Cypridium callosum Sanderæ* up"—was I aware that the remarks in the *Gardeners' Chronicle*, January 2, p. 1, under the heading of "Novelties of 1896," in which Mr. Cookson's success in raising C. *Lawrenceanum* Hyeuum, and kindred subjects true from seeds, is mentioned, was not correct so far as C. *callosum Sanderæ* is concerned. Mr. Cookson, however, hopes to raise it in a similar manner to the kindred C. *Lawrenceanum* Hyeuum, illustrated from his home-raised specimen in the *Gardeners' Chronicle*, January 16, p. 37.

and stout plicate leaves much resemble those of the *Acinetas*, and from the base descends a pendulous raceme of many wax-like orange-coloured flowers, tinted on the reverse side of the sepal with copper colour. The individual flowers are both curious and pretty, and the plant being evergreen is always ornamental. *James O'Brien*.

CYCLAMENS.

THE strains and races of *Cyclamen*, which form so beautiful a display at this season of the year, are all the result of variation under cultivation of one species, *C. persicum*; so that in this case the "improvement" cannot be attributed to cross-fertilisation. Lately, there have been fresh departures from the type which bid fair to be the forerunners of different forms, and are thus of great interest to students of evolution, as well as to florists. Whatever we may think of them now from the æsthetic point of view, it is certain that they will develop into forms of greater beauty in the future.

The illustrations (figs. 18, 19) show a variation which we first observed a few years ago, in which the petals branch so as to form crests and fringes analogous to what we see in many of the *Kails* (see *Gardeners' Chronicle*, May 7, 1887, fig. 118). Now Messrs. Low have taken the matter in hand, with the result shown in the woodcut—an additional figure

(fig. 18c) is given in anticipation, as showing what we are likely to get.

Another variation consists in the branching of the edge of the petals, so as to form a fringe analogous to what we have in the Chinese Primrose. This race was first brought under our notice by M. de Langhe-Vervaeke, of St. Gilles, Brussels, who designates his strains as "Papilio" (fig. 19). Specimens of this *Cyclamen persicum* var. *papilio* were recently brought under the notice of the Floral Committee, and were specially remarkable for the breadth of the petal, which was often less reflexed than usual (see p. 51 in *Gardeners' Chronicle*, January 16). No doubt these variations

A NURSERYMAN'S PARADISE.

LAST summer, while on a visit to northern Italy, a call was made by me at Pallanza, a small town on Maggiore, Italy's largest lake. The situation of this fair spot on a promontory of the western shore is very fine, but the most favoured position of all, viz., the actual tip of the promontory immediately beyond the town, is owned and occupied by Messrs. Rovelli Bros., nurserymen. From their beautiful gardens an almost uninterrupted view is to be had of the lake, from the encircling Swiss mountains on the north to the pretty rolling country at the foot of Maggiore.

to be wondered at that Mr. Rovelli should have determined to establish for himself an exotic nursery. Nor could he have chosen a more ideal position for such a purpose.

It may be stated at the outset that the strength of the collection is in its out-door growth of trees and shrubs, of which such a wonderful assortment, and so many rare and beautiful kinds, may be met with, that one can only attempt to give notes of some of the most important ones.

Such a series of specimens could not well be grown otherwise than under the Pallanza conditions of atmosphere. The temperature is very moderate on account of the shelter afforded from the north and east by the encircling Alps, and also, no doubt, because of the tempering influence of the vast sheets of water evaporating on either side of the nursery. The minimum winter temperature of the nights is only from 3° to 5° below zero of Centigrade, or 5° to 9° of frost according to the Fahrenheit scale. During the day-time, the minimum is about 3° Fahr. only of frost. Except during unusually hard winters, the night temperature may show a somewhat lower reading, but the variation is said to be always small.

Several of the rarer sorts of Asiatic and American trees attain in Messrs. Rovelli's nursery to a great height, and show a luxuriance of growth almost without parallel away from their native habitat. Several trees are especially noteworthy too, on account of their great rarity, notably a magnificent plant of *Keteleeria* (*Abies*) *Fortunei*, which Messrs. Rovelli consider to be unique (see *Gardeners' Chronicle*, 1884, vol. xx., pp. 128, 129, figs. 82, 83). In point of size, this is undoubtedly so, but since returning home, two other specimens in England have come under our notice, one with Messrs. Veitch & Sons, and the other in the arboretum of J. Rasbleigh, Esq., Menai, Cornwall. The Pallanza specimen measures 14 metres in height, and 120 metres through the foliage, or about 45 feet high, and a little over 39 feet through. Resembling a Cedar in appearance, when fully grown, *Keteleeria* (*Abies*) *Fortunei* is unique among Firs. The branchlets are sub-pendulous, the leaves pointed, about an inch in length, and either scattered or ranged in a spiral fashion round the branchlets. The cones (see *Gardeners' Chronicle*, 1884, vol. xxi., p. 348), reaching 6 inches in length, taper somewhat from base to apex. Its habitat is south-eastern China, where it may be found on the mountains to the north of Foo Chow in abundance.

Of the genus *Pinus* growing in Messrs. Rovelli's nursery, the following are worthy of mention:—

Pinus patula (Mexico), a very distinct species, about 45 feet in height; foliage spreading and pendulous. Veitch, in his *Manual of Conifers*, 1881, p. 172, says:—"A beautiful Pine, with spreading branches and long pendulous foliage. In its young state it is 'as like a green fountain as a green Pine,' on account of its bright green, drooping slender leaves, which quite conceal the stem and branches." (See *Gardeners' Chronicle*, 1885, vol. xxiii., pp. 108, 109, figs. 19, 20.)

Pinus longifolia, a tall, sparingly-branched species, with vivid green pendulous foliage. A native of the valleys of Nepal and Bhutan, India; one of the most valuable timber trees in the Himalayan region.

Pinus polustris, a grand specimen, some 45 feet in height. Native of North America.

Pinus Russelliana, foliage borne in tufts at the extremity of the branches; leaves very long and pendulous. This is a fine and distinct-looking tree, of somewhat tender constitution. Habitat, Real del Monte, Mexico.

Pinus insignis (California).—This well-known species in English nurseries may, at Pallanza, be seen 45 feet high at least!

Pinus Lambertiana is a species noted as being the tallest growing Pine known; in its native home it is said to reach 200 or 250 feet in height. Its cones are proportionately large, from 15 to 29 inches long, and its seeds are edible. Found in California, Oregon, &c.

The Pallanza collection is specially rich also in the genus *Cupressus*, and one is struck at once by their

FIG. 19.—A FRINGED CYCLAMEN FLOWER, *C. PERSICUM* "PAPILIO."

originate in some disturbance of nutrition at a particular stage of growth, but this explanation does not lead us very far in determining the proximate causation. In any case, it is desirable to record the first beginnings of changes which may ultimately prove of great horticultural importance.

In this connection we may also mention a variety, flowers of which have been sent us by Mr. Perry, gardener at Higham House, Colchester, and raised, as he tells us, between Messrs. Sutton & Sons' variety *C. p.* Butterfly, and an old strain of *C. persicum*. The flower nearly equals in size the first named, but is not pure white, there being a purplish stain at the edge of the orifice.

It was in this unique position that in 1848 the late Mr. Rovelli, acquiring several acres of land, established a nursery. Prior to that date Mr. Rovelli had for years held the responsible post of Director of the Borromean Islands—a miniature archipelago in Maggiore, close to Pallanza. These islands have been the property of the Borromeo family since the 17th century, in the last decade of which the barrenness of the Isola Bella was turned into loveliness by the formation of terraced gardens, stocked with luxuriantly-growing tropical plants and trees, with the addition also of a stately chateau.

The love of arboriculture and knowledge of exotics having been acquired in this lovely spot, it is hardly

gracefulness and beauty, as well as by their vast proportions.

Cupressus Hugelii (= *Benthami*), a specimen 15 feet in height.

Cupressus Comeyana, a variety of *C. torulosa*, from the Himalayan region, and possibly from China.

Cupressus species? "from the hills of India," 15 feet high.

Cupressus torulosa majestica, 10 feet.

Many *Thuja*s have also attained great heights. *T. gigantea* as much as 15 feet.

The so-called Umbrella-Pine of Japan, *Sciadopitys verticillata*, may here be seen in fine character, 20 feet in height, and beautifully furnished.

Of other choice specimens, *Cunninghamia sinensis glauca*, *Abies bracteata*, and *A. lasiocarpa* (*Lowiana*?) each attain to 40 feet, and *Araucaria brasiliensis* to nearly 50 feet in height—truly a noble tree.

Of all the rich assortment, perhaps the most beautiful is the graceful, free-growing, but somewhat tender *Pseuderis Kumpferi*, which, on account of its long, delicate green foliage, has a character at once charming and unique, in strong contrast to the majority of the Fir-tree tribe. This comparatively little-known species may here be seen as a large tree (see *Gardener's Chronicle*, 1884, vol. xxi, p. 581, fig. 112).

On the northern slope of the nursery promontory there is a grove of *Camellias* of the choicest kinds—large trees and small, some veritable giants of great age and others suitable for pot-culture: all healthy and well grown, including among their number the finest types known to commerce. It is surely a cause for no little regret that these beautiful flowering trees should have grown into disfavour of late, for though somewhat formal in their growth and inflorescence, they fill a place which notwithstanding modern introductions has not yet been superseded, and it is to be hoped that these Asiatic gems will shortly once more become popular.

Of out-door growing Palms, Messrs. Lovelli have a large and valuable assortment, and it is wonderful how their various points and peculiarities are displayed to advantage when growing naturally in the open ground, whereas in greenhouses they are often so cramped that an attempt at scientific comparison is rendered most difficult.

Hardy Bamboos too, which are now becoming so deservedly popular, are here in abundance. Fresh impetus has now been given to their culture by great private growers, notably by A. B. Freeman Mitford, Esq., of Batsford Park, whose invaluable paper read before the Royal Horticultural Society, and published in their *Proceedings* for July, 1896, should have a most beneficial influence in furthering the study and cultivation of Bamboos in England.

Many of the rarer kinds are still hard to obtain, though we venture to predict that the day will soon arrive when no great south-country garden will be considered complete without its collection of hardy Bamboos. *J. B.*

NURSERY NOTES.

ORCHIDS AT MESSRS. H. LOW & CO'S,
CLAPHAM.

Those of us who have been accustomed to pay visits to the celebrated London nurseries for the last thirty or forty years have seen many changes. It used to be a pleasure thirty years ago to visit Messrs. Low's, and inspect the Orchids and fine collection of Cape and New Holland plants. From there it was a mile or two further out to the Lea Bridge Nurseries of Messrs. John & James Fraser, where the collection of specimen hard-wooded plants and Azaleas were grown—the winners of many first prizes at the leading metropolitan exhibitions. Gradually but surely the famous Lea Bridge Nurseries have been absorbed by the builder of villas to let or "for sale on easy terms." Mr. John Fraser has moved to higher and better ground with a purer air at Woodford. Messrs. Low are now going through the same process of development. In a few more years the Clapton Nurseries, known to most of us since our

boyhood, will probably be seized upon by the vendor of villas. In the meantime, the Enfield Nurseries of Messrs. Low are developing into importance, and new houses of considerable magnitude have been built for the Cape and New Holland plants, which are not yet out of fashion; and now the Orchid-houses are being built, the Cattleyas have been sent to Enfield, and other things will follow. Dwellers in the east and north east of London are also feeling the effects of the fog to a greater extent year by year. Mr. Fraser found it so at Lea Bridge. Mr. John Ward, at Leytonstone, tells me that he cannot grow plants there that he used to grow well fifteen or twenty years ago. Mr. Low makes the same complaint, and I am in the same predicament, although I am further out than either of them. Tens, if not hundreds, of thousands of houses have been built in fifteen years in the east and north east, and the smoke of these rising heavenwards is doubtless the cause of so many good growers failing to grow plants as they used to grow them, and forcing us to seek a purer air further from London. There are some Orchids still doing well at Clapton, and first and foremost are *Phalenopsis*. A large span-roofed house was filled with these plants recently. The flowers of *Phalenopsis* open badly, or not at all, in foggy weather, but the health and vigour of the plants remain excellent. The rarer and more beautiful varieties are amongst the supposed natural hybrids. *Phalenopsis intermedia Portei* is a very fine form; has sepals and petals white, with purplish base, and the lip rich rose-purple and reddish spotted. *P. intermedia Brymeriana* is also a very delightful form. *P. leucorhoda* was also there in all its beauty, another hybrid which we owe to the agency of insects between *P. Aphrodite* and *P. Schilleriana*. There were also many fine plants in flower of *P. Schilleriana*, *P. Stuartiana*, and *P. amabilis*. The last three the most distinct and beautiful of Orchids.

A houseful of *Miltonia Roezlii* showed how well this fine species thrives in the London smoke. I have grown this plant well, and seen it well grown in other collections, but never before have I seen such a fine lot of plants as were to be seen here. Many of the white and blotched varieties were in flower, and the flowers do not suffer. Next to these are the *Cypripediums*. Mr. Low has acquired a fine collection of hybrid forms—the Tautz collection which contained many fine varieties, which have flowered well; doing well in the London atmosphere, the flowers last a long time in good condition. There are many now in flower, principally English-raised hybrids. *C. Morganii* is one of the best, it is a cross between *C. superbiens* and *C. Stonei*. The dorsal sepal is whitish with purplish veins, and the petals about 6 inches in length, are freely spotted like *C. Stonei platytonium*, and it is quite as handsome, and perhaps more elegant. *C. leucorhodium*, a lovely variety, raised by crossing *C. Roezlii* with *C. Schlimii abillorum*. This is to me the most fascinating of garden varieties, the ivory-white of the upper sepal, petals, and lip, shading to delicate rose and rose-pink, are lovely. A plant of *Measuriana* is in flower; it is one of the best of the *C. venustum* crosses. The whole flower, but chiefly the dorsal sepal, is veined with green from *C. venustum*, but the lip and sepals show the *C. villosum* parentage. *C. Lathamianum* is distinct and handsome, a cross between *C. Spicerianum* and *C. villosum*. The reverse cross has also been raised, and named *C. Hera* and *C. Bellona*; the two were in flower together, and seemed to be much alike. *C. Sallieri*, from *C. villosum* and *C. insigne*, raised in France, is also very fine as a garden hybrid. *C. Madame George Truffaut* was opening its flowers, and promised to have very rich and dark-coloured blooms; its parentage is *C. Stoneii* and *C. ciliolare*. Of the *C. insigne* varieties, there are *C. Sandersii* and *C. Sandersianum*, with some other fine varieties not in flower, but of great commercial value.

I have left *C. Lecanum* until the last, but Messrs. Low possess all the best varieties; and as many of them are now in flower, one can judge of their merits.

C. Lecanum superbum, Low's variety, is not the largest, but the flowers are the most elegant and prettiest of the collection; the upper sepal is

pure white, beautifully spotted violet. *C. L. giganteum* is large and handsome. *C. L. compactum* is a fine form of superbum; but there is much variation in the large collection.

Amongst rare and beautiful things in flower was a charming *Lælia*. "A rare plant even in Brazil," L. Lindleyana, the flowers are small in size, delicate bluish shading to purple. It is figured in *Botanical Magazine*, tab. 5149, as *Cattleya Lindleyana*. Only a few *Dendrobies* were in flower, *D. heterocarpon*, the well known parent of the best garden varieties; *D. Dominianum*, delicate rose-purple; *A. riles falcatum* *Houlletianum*, yellowish flowers, purple spotted. There is also a lovely pure-white variety of *Cattleya Gaskelliana*; the entire flower pure white with a stain of yellow in the throat. An immense number of plants of *Agavecum sesquipedale* were in flower, with smaller number of *A. obtusum*.

The last plant that I noted is *Dendrobium Johnsonii*, which has pretty pure-white flowers, the crest of the lip beautifully marked violet-purple. *J. D.*

MESSRS. SUTTON & SONS, READING.

On Wednesday, 20th inst., I was enabled to visit this nursery and view the *Primulas* and *Cyclamens* at present in bloom. The *Primulas* are arranged in batches of one colour, and so blended in regard to colours as to make them appear very fascinating. They are exhibited in great variety, and their flowers are of great size and beauty. There were remarked on one side of a house plants of *Primula sinensis stellata*, known commonly as Sutton's Star *Primula*, which was one mass of white flowers, with occasionally a flake of crimson in the star-like blossoms. The foliage resembles that of *P. sinensis*, and the flowers are borne in tiers one above the other in profusion.

The "Giant" *Primulas*, with single flowers, were noticed as being very vigorous in growth, and in some instances in flower, the flowers being as large as a crown piece. The plants were arranged in batches of colour. Of named varieties that were particularly pleasing, mention may be made of Pearl, Brilliant Rose, Royal White, Reading Scarlet, do. Blue, and do. Pink, Snowdrift, Gipsy, and Rose Queen.

The double flowered varieties in the scarlet, pink, blue, white, and flaked, were the perfection of *Primulas*.

The *Cyclamens* pre-ented a brilliant display, arranged in large batches like the *Primulas*, and I filleg several houses. The colours are exceedingly varied, and range from white, red, rose, pink, crimson, and purple. The most noticeable varieties were *Butterfly*, a pure white flower of great size; *Salmon Queen*, a variety with flowers of brilliant pink, and finely-marked leaves; *Vulcan*, a crimson-coloured flower of striking proportions. These plants are so sturdily grown that sticks are not needed. *R. C.*

CELERY-GROWING.

A CORRESPONDENT of *American Gardening* gives an account of his method of growing Celery, from which we extract the following particulars:—

"I now have very fine Celery grown in rows at an average distance of 1 foot apart, i.e., two rows, 6 or 7 inches apart, with an 18-inch space between them. Boards are set on both sides of the double rows when the plants are about half grown. The boards should be kept well apart until the Celery has nearly reached its growth, so as to keep the leaves green and exposed to the air. The boards may be held in place by a short piece of board with notches sawed in both ends and placed on the others, so as to hold them the right distance apart.

"The space between the rows was mulched with manure or other material that would hold moisture. Then I turned water on the rows and kept them thoroughly wet. The water was taken from a brook nearby, and I elevated 6 or 8 feet in a water-tank, and distribute I over the piece with iron pipes and hose. One could almost see the plants grow.

"When the Celery had about got its full growth the boards were crowded close together, and the blanching was completed in a very few days. The result was a large growth of well-blanching Celery.

"The advantages of this method are that about three times as much Celery can be grown on the land as by the old plan of setting it in wide rows; two rows being boarded together, it saves one-half the boards; no earth is put around it, which saves washing the Celery. If the rows are mulched, it keeps down the weeds and retains moisture. No one will succeed with this plan except on very rich soil, and when the rows are so close together irrigation is indispensable.

"This method is only adapted to early Celery and the self-blanching varieties. White Plume Celery plants are grown in hot-beds for the earliest Celery; followed by the Golden Self-blanching for late fall use.

"For winter Celery I set the Giant Pascal, Half Dwarf, and Golden Heart in rows 1 foot apart, leaving some wide rows to stand in when working it. This is irrigated the same as the early Celery, but is not hauled or handled, as it blanches well after being stored in the cellar or trenches for winter."

Selected specimens of Celery fetch a fancy price, so that the writer says he was getting for such specimens over 30 dollars per square rod, or at the rate of 5000 dollars per acre: "Ordinary Celery paid me at the rate of 300 dollars to 400 dollars per acre, or less than one-tenth of that which was grown by special culture and marketed without the help of the commission dealer.

"By comparing the profits of these two shipments it is easy to see where the money is in gardening. In the labour required to grow them there was but little difference. The greater profit in the first instance was made by using large quantities of fertilisers and irrigation."

AMERICAN NOTES.

NEW SWEET PEAS.

EVERYTHING goes to show that the Sweet Peas will retain this year the remarkable favour which they have been developing for several seasons past. The methods and the material foundation furnished by Mr. Eckford have been rapidly utilised and adapted in this country. There are many Sweet-Pea amateurs and professional experts in the Eastern States; but California is now the scene of most of the commercial variety-breeding and seed-growing. Immense tracts of land are there given up to the production of Sweet Pea seeds in a specially favourable climate, and in the charge of notable specialists. A very promising list of new varieties is offered for 1897.

SPINACH.

Perhaps the best of recent contributions in horticultural lines from American Experiment Stations is Professor L. F. Kinney's bulletin on Spinach. He reviews critically the history of the development of our garden varieties, their botanical origin, and gives a classification as the result of his field study, embracing practically all varieties known in this country. According to Professor Kinney, all the garden varieties of the commonest species (*Spinacea oleracea*), may be reduced to four types—1, Norfolk, or Bloomsdale group; 2, round-leaved; 3, thick-leaved; and 4, prickly-seeded Spinach. Besides these, there are occasionally grown New Zealand Spinach (*Pterogonia expansa*), and Mountain Spinach (*Atriplex hortensis*). A thorough study of cultural methods for market gardeners is added.

HORTICULTURAL INSTRUCTION AND THE "SURVIVAL OF THE UNLIKE."

The recent publication of Prof. Bailey's *Survival of the Unlike* (see p. 69), marks a great development in American methods of horticultural instruction, and less significantly indicates a recent widening of the field of evolutionary philosophy. Within the last ten years the few agricultural colleges in this country were mostly of the training-school type, giving elementary manual instruction. The recent notable extension of agricultural courses into universities and institutions of higher learning, has had a tendency to put horticultural instruction into a basis like that occupied by related natural sciences. Thus, students

of horticulture daily handle the most profound problems of vegetable physiology and developmental philosophy. They take up theoretically and experimentally such problems as are discussed by Geddes, Weismann, Nageli, and Bailey. Professor Bailey has himself been a leader in this sort of horticultural teaching; and his new book may be best understood as an expression of that idea. It deals philosophically with the ultimate principles governing the

appearance is sufficiently indicated in the woodcut (fig. 20). We can only add that the flower-segments are white, with a pale purple spot at the base externally, but purplish internally. The filaments and anthers are both purplish. As the collections from Chitral get examined, we shall doubtless hear more of what is, in any case, a pretty garden Tulip, probably an albino of some known species.

THE LILIES OF THE PACIFIC COAST.

THE Pacific coast of the United States is wonderfully rich in members of the Lily family. With nearly forty *Calochorti*, over twenty *Brodieas*, and thirty *Alliums*, nine *Fritillarias*, and ten *Erythroniums*, as many or more *Liliums*, and fifty other species distributed among twenty-five genera, the Liliaceae of the Pacific slope include a grand total of over one hundred and seventy species in a vast and comparatively unknown region, the exploration of which annually adds new species, or proves the existence of forms described by the earlier botanists, and since lost sight of. I doubt if there is any other region in the world where the Lily family is so rich and varied.

The number of *Liliums*, or true Lilies, on the coast, varies according to the nomenclature followed. *The Botany of California*, published in 1880, mentions eight species and one variety. Mr. Baker more correctly, as I think, distributes the same material into fifteen species and varieties in his synopsis of the genus. These species can be divided into several groups, according to their natural affinities. *Lilium Washingtonianum* and its varieties, with the nearly related *L. rubescens*, will form the first of these groups, and into the second will naturally fall *L. Columbianum*, *L. Humboldtii* and its varieties, and *L. Bloomerianum*, which is also known as *L. Humboldtii*, var. *ocellatum*. *L. Bolanderi*, too, shares in the solid ovoid bulb and leaf-character of this group, although its flowers differ in form.

A third group, and a very large one it is, will contain the western relatives of *Lilium superbum*, large bell-shaped Lilies with rhizomatous roots and revolute flowers. These are *L. pardalinum*, *L. Roezlii*, and *L. Varei*, with the innumerable forms of *L. pardalinum*, some of which, as *L. californicum*, *L. Bourgei*, and *L. puberulum*, are often treated as species. This wonderfully varied group is connected by a close chain of intermediate forms, possibly crosses, with the next group, which consists of the western relatives of *L. canadense*. In this group of small-flowered bell Lilies, *L. parvum* is nearly as various in its forms as is *L. pardalinum*; but *L. maritimum* is, as far as my observation goes, strictly monotypic. The type of *L. parvum* and *L. maritimum* have funnel-formed flowers.

Lilium Parryi is closely related to the *Pardalinum* group, differing only in having trumpet-shaped flowers. In growth, it can hardly be distinguished from *L. pardalinum*.

Of these eleven species, *Lilium pardalinum* is most widely distributed, being scattered from central California to British Columbia, and eastwardly to the shores of Lake Winnipeg. *L. Washingtonianum* inhabits a long and narrow belt in the main Sierra Nevada range, and in the Cascades to British America. *L. Parryi* is found in Arizona as well as in its original location in southern California, and *L. Columbianum* is found to extend far east of the Cascades in the Columbia River valley, but with these exceptions these Lilies belong to the mountainous regions of the Pacific coast proper in the Sierra Nevada and coast ranges. *Carl Parry*, in "Garden and Forest."

FIG. 20.—TULIP FROM CHITRAL. FLOWERS WHITE.

origin and distribution of varieties as those principles are to be seen exemplified in the fruits, flowers and vegetables with which the horticulturist has to deal. F. A. Waugh.

A NEW TULIP.

At the last meeting of the Royal Horticultural Society, Messrs. Sander exhibited a pot of what we are constrained to call a new Tulip, for its specific name has not yet been accurately determined. Messrs. Sander inform us that it came from Chitral. Its general

TROPICAL SEEDS AND PLANTS.—Seed catalogues are so numerous, that any special mention of particular examples would be unfair unless they are marked by some special peculiarity. This is the case with Messrs. J. P. WILLIAMS & BROTHERS, of Henaragoda, Ceylon, whose catalogue contains a descriptive list of tropical plants suitable for cultivation on a commercial scale.

THE WEEK'S WORK.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Droppore, Maidenhead.

Subtropical Plants.—Seeds of some of the slower germinating species should now be sown, viz., *Canna*, *Grevillea*, and *Encalyptus*. The seeds of *Canna* germinate quickly if before sowing them they are soaked for twenty-four hours in water which is kept rather warm. Some of the novelties of the Crozy section of *Canna* have beautiful flowers, and handsome, distinct looking foliage, and mostly they are of a dwarf habit. Plants which have been sown may now be increased by cutting up the rhizomes into pieces with one or more buds, potting them into pots of 5 or 6 inches in diameter. After potting and watering them slightly, place in an intermediate-house, or plunge to a bed of leaves having a mild heat.

Caranations.—Those of the "Marguerite" type usually raised from seed may now be sown early if required to make an out-door display in the month of August. The flowers of this variety are also admirable for cutting at a time when most of the other varieties have run out of bloom. The seeds may be sown in small shallow boxes or pans filled with sandy-loam and leaf-soil, standing these on a mild hot-bed till the seeds germinate. Then removing to cooler quarters, and pricking them off into other boxes with two pairs of leaves have been made. The seed of the white variety may be relied upon to produce plants which come true, and the white, fringed blossoms are attractive and useful in the autumn for a variety of purposes.

Sweet Peas.—For the production of early blossoms, seed should be sown forthwith in pots placed in a late Peach-, or other forcing-house, with a temperature of 40 to 45°, and immediately the plumule pushes through the mould, the pots should be transferred to a cold-frame. As a means of making the most of choice varieties, the seed of which is dear and scarce, sowing in pots is to be recommended, and if six or eight seeds are sown in a small 4½ inch potful may be turned out in the spring without loss. Sweet Peas look well in the borders in clumps of three or more potfuls, or they may be put out in lines as usual. Where space can be spared in the kitchen garden, a long row or two should be sown for cutting from, and the soil usually being richer than in the flower-garden, the production of flowers is greater and longer continued if the seed-pots are kept picked off. The colouring of many of the newer varieties is rich and effective, and a dozen good ones will be found in the following—Blanche Buzpe and Emily Henderson, two good whites; Mars, bright fiery crimson; Countess of Radnor, delicate mauve; Lady Penzance, fine bright rose; Princess Beatrice, a popular pink variety; Captain of the Blues, pale blue and purple; Primrose Queen, pale primrose; Senator, bronzy purple; Dorothy Tompat, rosy mauve; Boreatou, dark maroon; Monarch, bronzy crimson and violet.

Begonias.—The tuberous-rooted Begonia has now become popular as a bedding-plant, and for a wet summer it is as such, in advance of the Pelargonium. The past two summers have not been "Begonia summers," but a position can generally be found for a bed or two, where if kept fairly moist, the plants are sure to make free-growth and flower well. Old tubers should be kept cool for a little time longer, unless it is wished to increase any of them by division. Preparatory to starting them for this purpose, the tubers should be placed closely together in boxes or pans, upon a layer of leaf-mould or Cocoa-nut-fibre-refuse, and just covered with the same. They then require to be put where there is enough warmth to start them very slowly into growth. A slight dewing over with tepid water should be afforded the mould when it appears to be dry. When the new shoots have reached a height of 1 inch, the tubers should be cut up into as many pieces as may be desirable, reserving one or more shoots to each, dipping the cut parts in fines and or charcoal powder, and potting them singly. Very little heat should be applied, as it is essential that a sturdy growth be made. If seedlings are required, seed should be sown forthwith. For this purpose the single erect flowering varieties are the best. The nurseryman sell Begonia seed in separate colours, which come fairly true to kind. As the seed is very minute, especial care must be bestowed on the sowing of it; and small square, shallow boxes or earthenware pans (not new) should be chosen for the purpose. Place 1 inch of crocks over the bottom,

and then some rough leaf-mould, and having some finely sifted peat, leaf-soil and sandy loam in equal proportions, fill the boxes, &c., pressing the soil firmly and making the surface smooth and level. Scatter the seed thinly and evenly over the surface, no sand being used before or after sowing, but cover closely with a piece of slate or glass, and plunge the boxes or pans in a gentle bottom-heat affording little if any water before germination has taken place. The surface-soils should not be allowed to become dry, and if the sheets of glass are carefully shaded from sunshine, so no water will be required before the plants appear. In the case of the pans getting very dry, partially immerse them in warm water till the soil is made moist, but without allowing the water to rise quite to the surface of the soil. Fibrous-rooted Begonias of the superflores type may be raised in the same way, several of the varieties as *Crimson Gem*, and others of rose and pink shades, are very free of growth and flower, and of use in forming distinct beds of colour or for mixed bedding.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Heating the Houses.—For several days past cold winds have prevailed, penetrating the Orchid-houses, and rendering heavy firing a necessity. As the plants suffer at such seasons from the aridity caused by hot-water pipes highly heated, no more heat must be employed than is really necessary; at the same time, fluctuation in the temperature to any great extent should be avoided. As a means of maintaining the proper degree of warmth, without heating the hot-water pipes too much, some garden-mats should be laid along the lower part of the roof at dusk, making them secure against the wind. As an experiment in this direction, I have drawn down the wooden lattice blinds on several of the houses, letting them down above the mats, and have found them to be useful in keeping the mats from being shifted by wind, and preventing to a perceptible degree the wind impinging on the glass, thereby keeping the houses warmer with less fire-heat. Houses as covered have not the stuffy air that is generally noticeable when thick canvas-blinds are used for the same purpose. Where much artificial heat is used, its effect may be obviated in part by the admission of air whenever this is practicable or desirable, and by damping the soil or floor beneath the hot-water pipes several times daily. During the winter, the mistake is sometimes made of maintaining a hot, moist, growing atmosphere for the Cattleyas and East Indian and Mexican Orchids, thereby causing weak growth, and sometimes spot on the leaves, and various forms of ill-health in the plants, which if not observable at the time, make their appearance soon afterwards. It is better for the plants if a moderately low and even temperature be maintained until the sun gains power later on, and it recuperates them naturally. The Odontoglossums of the cool-house feel the effects of artificial heat more than any other species, and much judgment is needed in maintaining the warmth from falling below 45°. Just before sunset, if the frost be severe, the temperature of this house may fall a few degrees below its proper standard, still no more heat should be turned on, otherwise when the house is covered for the night the warmth will be higher than is desirable. In this house many of the plants are showing flower-spikes, and careful inspection of the plants by night for slugs and small snails will be very desirable, in view of the ravages done by these creatures. The Masdevallias must also be daily examined, slugs having a great liking for the young growths. If slugs abound, rare and valuable plants should be stood upon inverted pots placed in saucers filled with water, and even then the safety of the plants cannot be guaranteed, as slugs may be hiding amongst the growths or compost, hence the need for a daily examination of the plants.

Calceolajugus is an attractive plant, whose flower-spikes arise from the young growths at this season. When the plant is cultivated in the same house as *Odontoglossum crispum* it usually deteriorates, but if it be placed in the drier and slightly warmer Masdevallia-house during the winter, it keeps in good condition. From the time the flower-spikes appear on the plant it should be afforded water in abundance each time it becomes thoroughly dry, but not kept always saturated, or the black-spot will quickly disfigure the young leaves, and eventually cause the decay of the growths and flower-spikes. Repotting may be done after the spikes are removed, or the flowers fade.

Zygopetalon Clagii, a hybrid between *Z. maxillare* x *Z. crinitum*, requires a course of treatment iden-

tical with that which suits *Calceolajugus*; *Z. maxillare* may also be accommodated in the Masdevallia-house, or at the warmer part of the Odontoglossum-house. It is a species which is found growing in a state of nature on the stems of Tree Ferns, and if possible it should be fastened to a piece of the same, stood upright in a flower-pot, and made secure with a filling of crocks, &c. Now that the plant has begun to grow, it should be afforded water liberally.

The Cattleya-house.—The plants of *C. Trianae* now prominently showing their flower-buds in the sheaths should be more abundantly watered at the roots, and as the flowers open the quantity should be lessened by degrees, and the plants kept moderately dry till growth re-commences.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Top-Dressing Orchards, &c.—Take advantage of frosty weather to wheel or cart manure on to orchards, and spread it evenly over the grass. In the spring a chain or bush-harrow may be used to pulverise and scatter the manure and worm-casts. Good dressings of manure should also be wheeled on to fruit-reef quarters, where the distances at which the trees are planted admit of vegetable crops of various kinds, such as Potatoes, Cabbages, Lettuces, and Turnips being taken. This kind of work may be done when it is too cold to proceed with the mowing of wall trees. The manure should be dug or forked into the land as soon as the conditions are favourable; care being exercised not to dig deep enough to injure the roots of the trees, which should receive the first consideration. In the case of orchards generally, the necessity for annual or bi-annual top-dressing of the ground is too often overlooked. Crops of fruits are gathered, the grass is mown for fodder, and nothing is given back to the land to compensate for what has been extracted. This results in an impoverished state of the soil, and consequent poor crops upon the trees. Such circumstances occur even on farms or estates where a skilled and generous method of culture is afforded to cereal and root crops; yet were orchards treated with equal liberality, they would yield more profitable returns than either, taking one year with another. Dutch-heaps which have been turned once or twice during the last twelve or eighteen months make useful material for top-dressing orchards; but if good farm-yard manure be laid on to the thickness of 1 or 2 inches, this will be productive of better results. An occasional dressing of leaf-mould will prove advantageous to trees growing in stiff soil.

The Training of Wall Trees should be pushed forward during favourable weather, when the work can be comfortably and properly done. It may be done after the sun has shone forth in frosty weather, commencing on the south wall in the morning, and following the course of the sun to walls having south-west and westerly aspect. The men should retire to the packing-shed, or other suitable place, after the sun has gone down, where they may cut up shreds, and sort over old nails for using the following day, which work should be resumed in the morning until the sun shines forth. Thus, the handling of nails, shreds, branches, and hammer, may be performed with speed and precision by fingers unnumbed by cold. The training of espalier-trees should also be proceeded with, leaving sufficient room on the ties to prevent them cutting into the branches as these become larger.

THE KITCHEN GARDEN.

By W. FIFE, Gardener, Highclere Castle, Newbury.

Mushrooms.—Fresh beds may now be made, to come into bearing early in the spring. There is always a little difficulty at the present season in getting the manure into a suitable condition, and I have found it advisable to add about a quarter of the whole of dry loam, and turn the heap two or three times at intervals, to mix it thoroughly. It should remain in a heap after the last time of mixing for one day before making it into a Mushroom-bed. The bed should be made in the usual manner, pressing or beating it firmly together as the work proceeds. As soon as the heat has risen to 75°, the spawn may be inserted, and the bed soiled at once. The mixture of loam with the manure will prevent any excessive heat, arising in the bed, and the produce will be flesher, and superior in quality than when manure only is used. If no convenience exists for Mushroom-growing indoors, a bed or beds may now be formed outside with every prospect of success. A dry spot must be chosen, and the material of which

to build the beds prepared by shaking it over, and separating the longest of the straw; then turn it over on alternate days for a week till thoroughly sweetened, when the bed may at once be made up in the form of a ridge, 3 feet wide at the base, and as much in height, beating the dung very firmly, and covering it when finished with a thick coat of litter, or with double mats, till the heat rises to the requisite height, when the straw should be inserted and 2 inches of soil put over the whole, and well beaten with a spade, again covering it thickly to retain the warmth and protect it from the weather.

Jerusalem Artichokes.—These tubers should be lifted and sorted into sizes, the largest being laid by for use, and those of medium size and good shape reserved for planting. This may be done at once if the ground be in a workable condition. Soil of good depth and fairly rich, is necessary to ensure a good crop of tubers; and let the rows be 2½ feet to 3 feet apart, and the sets 18 inches apart. In addition to the usefulness of the roots as a vegetable, the tops may be made to form a screen to objectionable features during the summer season. The white is the best table variety.

Mint and Thyme.—Roots should be lifted and planted in shallow boxes to afford a supply of shoots in the spring. Cover the roots with soil to a depth of 2 inches, afford water, and place in a temperature of 60° to 65°.

Potatoes for Planting.—All garden Potatoes reserved for planting should be spread out thinly on shelves or in shallow boxes. The early and second-early varieties will in most cases have begun to sprout, and if allowed to remain in heaps, or in a dark shed or cellar, they will deteriorate. Tubers for garden planting should be sprouted before they are planted, but the sprouts should be stout and sturdy, to ensure that they must be arranged in a single layer, placing them with the eye-end uppermost in a place where the light reaches them, and where frost cannot enter. Where Potatoes are grown in large quantities in fields, it is not possible to treat them all in this manner; still, these should now have the longer shoots removed if growth has commenced. Potatoes stored for consumption should be served in the same way, as if allowed to make a lot of long sprouts they are poor eating. Keep them as cool as is consistent with safety, and covered with straw or bat mats.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

Succession Vines.—Such Vines, the forcing of which began about December 1, will now be breaking into growth, at which stage they do not require to be so heavily syringed, especially if the weather be sunless, much moisture at such times causing the points of the shoots and sometimes entire shoots to damp off. Where beds of fermenting materials are used in the vineries, it will be found beneficial to the Vines to turn the beds over occasionally to liberate the ammonia and moisture, thereby doing away with the necessity for much overhead syringing. Some gardeners may think this plan of using beds of fermenting materials old-fashioned, but it is not the less beneficial to the Vines, especially when these are aged, the roots breaking much stronger and the foliage coming stronger and healthier. I would, if stable-manure and labour were available, use these heaps in all my vineries, and I am sure, if the practice were common, instances of Vines eaten up with red-spider would be less often observed. As soon as the best growths are discernible, the weaker ones should be removed with finger and thumb, thus throwing the energies of the Vines into those intended to remain. All shoots carrying a bunch of Grapes should be stopped two joints beyond the bunch, the trellis being filled with the next break, thus causing the sap to be directed to the bunches. As the flowering period is approached, the atmospheric moisture should be gradually reduced, at the same time the night temperature raised to from 65° to 70°, with a corresponding rise by day. Afford a little ventilation whenever the conditions by day are favourable; remove the rods of free-setting varieties every day about noon, and fertilise Muscats and other shy-setting sorts, by means of pollen carried from bunches of Black Hamburghs by means of a small box and a camel-hair pencil.

Late Vineries.—All Vines remaining unpruned to this date must now be pruned without delay, dressing every wound made with knife or saw with styptic, or painter's knotting, in case of bleeding later on. Wash the Vines with Gishurst

Compound soap, at the rate of not more than 4 ounces to the gallon of water; clean the wood-work, glass, &c., with soap-suds, and take off the surface-soil of the inside borders if spongy and much compacted by tramping; give a dressing of good loam, to which has been added fair proportions of lime-rubble and soot, beating the whole firmly down with a steel fork. Lightly prick up borders not so treated, sprinkle over the surface a moderate dressing of Thompson's, Veitch's, or Wood's manure (all equally good). The borders may then be covered with a layer of stable-litter, so as to preserve a tidy appearance, and prevent the soil being carried on to the paths, &c. Afford warm water copiously to the borders, preparatory to starting the Vines next month.

Carefully examine hotted Grapes for bad berries, for my experience is that they are keeping very badly this season.

Succession Peach and Nectarine-houses.—The buds on trees which were started about January 1, and now expanding, should be afforded fumigation with tobacco to kill aphids. Overhead syringings should be discontinued as soon as the flowers begin to open; a moderate drenching on the ground on fine days being found sufficient during the period of flowering. Another house may now be started if a constant supply of fruit be required. The pruning of the trees in later houses should now be carried out without further delay, and the trees washed, and fastened to the trellises. The later houses should be kept as cool as possible, closing them only during very severe frosts or high winds. If the trees are infested with scale, the XL All plant-wash will be found a capital dressing for them, and should be applied with soft brushes, using it in a very weak solution on the younger wood. Use it last year on some badly infested trees in a cold house, which were but little troubled with scale afterwards. On pruning these trees the other day I was pleased to find scarcely a trace of the insects on them. Keep the borders in late houses regularly watered; drought at this season being a common cause of buds dropping later on.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoop, Luton.

Camellias.—Attention should be given at this season to plants of the Camellia trained on the walls of the greenhouse and conservatory, sponging the leaves if they are infested with the black fungus with some soap-suds, in which a little flowers of sulphur have been dissolved; or if scale infests them, with an insecticide. When the leaves of the Camellia are merely dusty, it is sufficient to rub them with a soft, dry cloth. If the foliage has an unhealthy appearance, the drainage may require looking to, and in any case a surfacing of fresh soil, consisting of loam, peat, leaf-mould, and soot, will be required, after removing the upper-crust down to the roots. Borders containing aged plants being filled with roots, are benefited with doses of liquid-manure containing a small quantity of soap. If there are thrips on the plants, use XL All vapour for several nights in succession.

Fuchsias.—Large aged plants must not be allowed to become very dry at the root, or many of the roots will perish; and at this season such plants should be hard-pruned, and put on one side, previous to starting them in warmth next month.

Scribneryana (Jacobinia) Gheisbreghtiana.—Any plants which may have passed out of flower should be cut back, and a reduced quantity of water afforded. When the plant starts to grow again, and short-jointed cuttings can be obtained, propagation may take place. Strike the cuttings in bottom-heat of 80°, and pot-off as soon as they are rooted, using 60's, and a mixture of one part of loam, one of leaf-mould, and one of sharp sand. When established, haul them in and keep them in a cold frame during the summer months.

Andropogon Lupaninus.—This plant should have its leading shoots shortened back, and cuttings with a heel taken as soon as the shoots are about 3 inches long. These strike in a mixture of leaf-mould and sand in slight bottom-heat under hand-lights, and should be potted-off when rooted. They do best in the stove during the spring months. When shifting them into their flowering-pots, say 6-inch ones, a mixture of half peat, one quarter loam, one quarter leaf-mould, with plenty of sharp clean sand and charcoal, should be employed. In the warmest part of the year, the plant does well in an ordinary garden frame, and in September it should be removed to the intermediate-house. Aged examples of these plants make good material wherewith to fill baskets to be hung in the stove when in flower.

Impatiens.—Plants which were pruned hard during the flowering season will now be past their best, and attention should be directed to obtaining a sufficient number of healthy cuttings in the course of the next month. After shortening back the growths and clearing the plants of scale, place them on a shelf close to the glass, in a house having a temperature of 55° to 60° during the winter, over the root. The roots afford a means of propagating the plants by cutting them into small pieces, and placing them in pans of sandy soil in heat.

The Forcing-house.—Continue to place fresh batches of bulbs and plants in this house at intervals, using the precautions advised in a previous Calendar.

THE APIARY.

By EXPERT.

Honey as Food.—In a recent issue of the *American Bee Journal*, Professor Cook, a great authority on the scientific side of bee-keeping, contributes an excellent article on "Honey as Food," in the course of which he says, after referring to the necessary constituents of a perfect food, the inorganic elements, like water, salt, phosphate, carbonate of lime, &c., the non-nitrogenous organic containing oxygen, hydrogen, and carbon, illustrated in starch, the various sugars, and the fats, says, "The digestion of food is simply to render it osmotic, or capable of being taken through an organic membrane capable of being absorbed." We eat starch; it is non-osmotic, and would lie in the stomach and intestines indefinitely, except that by digestion it is changed to a glucose-like sugar by the action of the liver, which is very osmotic, and so absorbed from the alimentary canal into the blood. Cane-sugar, though somewhat osmotic, is not readily absorbed, nor is it readily assimilated, even though it pass into the blood; thus cane-sugar must be digested or changed into a glucose-like sugar. Bees gather nectar from the flowers, and as they seize it, or draw it from the flowers, they mingle with it a kind of saliva or ferment from their upper head gland and the large glands of the thorax, and thus transform it into honey, which contains almost exclusively a reducing sugar, and not cane-sugar. Thus bees do to nectar what we do to cane-sugar—they transform it into a more osmotic and more assimilable glucose-like sugar. We call this in our case digestion of the cane-sugar, and it is just the same when the bees do it. If anyone prefers, he may call it transformation. In any case, it makes honey a safer food than cane-sugar, and we do well to eat it more generally, and it is especially desirable as food for children.

Children should be given all the honey at each meal-time they will eat. It is safer; will do away with the morbid longing for candy and other sweets, and, in lessening the desire, will doubtless diminish the amount of cane-sugar eaten. Thus, if cane-sugar does work mischief with health, the harm may be prevented. There can be no doubt that in eating honey our digestive machinery is saved work that it would have to perform if we ate cane-sugar; and in case it is overworked and feeble, this may be just the respite that will save from a breakdown. Again, if cane-sugar is absorbed without change, it will be removed by the kidneys, and may result in their breakdown, and so physicians may be correct in asserting that the large consumption of cane-sugar by the nineteenth-century man is harmful to the great eliminators, the kidneys, and so a menace to health and long life. It may be urged in reply to the above that honey is a poison to many. This is not the sugar of the honey, but some other element; very likely the formic acid, or perhaps the extract from the flowers. I speak from the fact that the deleterious element is the formic acid added to the sweet by the bee. This keeps the honey from fermentation, and is not harmful to many—only occasionally a person is unable to eat it.

Snow.—Keep all snow clear of the entrances to hives—this is very essential, more particularly at this time of year; and replace candy where required.

ORIGIN OF MAIZE.—Some few years since, the late Dr. SERENO WATSON received from Mexico several plants of Maize, of which the seedlings were examined by the Professor, and by him named *Zea canina*. According to an article by Dr. Huxstrey, this plant originated as an accidental cross between the cultivated Maize and "Totocintle," or *Euchloa mexicana*. It is further surmised that Maize may have originated by hybridisation in this way.

EDITORIAL NOTICES.

AVERAGE TEMPERATURE for the ENSUING WEEK, deduced from Observations of Forty-three years, at CHISWICK—59° 25'.

ACTUAL TEMPERATURES:—

LONDON—JANUARY 27: MAX, 41°; MIN, 29°.
PROVINCES, JANUARY 27 (6 P.M.): MAX, 41°; VALDEIRA,
MAD., 32°; ABERDEEN

The Report of the Royal Horticultural Society, reprinted in our last issue, must be considered on the whole as a very satisfactory document. It shows that good work is being done; and good management is also obvious. It is gratifying to learn that the renovations at Chiswick, which have been in hand so long, are at length completed; and eminently satisfactory to know that the Council have every reason to congratulate themselves on the selection they made to fill the office of garden-superintendent vacated by Mr. BARRON. What is now wanted is to make Chiswick more useful than it is to the gardening public. The trials carried out there are only of limited value, and as a rule add little or nothing to horticultural knowledge, and contribute as little to its progress. They show that, under circumstances as they exist at Chiswick in a particular season, one variety may be better than another, but what is the cause of that diversity is not considered, nor is any hint given in what directions we may look for future progress—hints such as the observations of the plants during growth should assuredly supply. A standard collection of the best and most suitable varieties of flowers, fruits and vegetables, should be kept for the purposes of identification and comparison by gardeners. From these collections inferior sorts, unless in some way of special interest, should be eliminated. In all possible ways, Chiswick should be made a model garden, where the visitor might be sure to see all novelties, and the most approved methods of gardening carried out in all departments so far as circumstances permit.

We regret to have to renew our protest that no effort was made last year to secure the attendance at Chiswick of the Fellows at stated times, or even of the members of the several committees as a whole. This year again the Council takes no pains to bring the Fellows to a garden on which they have expended within the year £1870, or, with the necessary reductions, £1500. Of course, any Fellow can go any day he chooses, and some, perhaps, do; but the bulk of the Fellows are not likely to go unless for some special purposes.

We throw out for consideration a proposal that a combined meeting of all the committees be held in the garden during the coming summer. The purpose of this meeting should be to discuss subjects of common interest to all the committees, such, for instance, as the preposterous number of awards to which the Council very properly draw attention, the revision of the rules of judging, the selection of new members for the ensuing year, the relation of the committees to the council, the course of action to be recommended to the council, and other matters of that kind as the circumstances of the time may suggest or render necessary. The formal business meeting over, an adjournment might be made to the trial grounds and to the various houses, and if some of the fellows felt disposed to take luncheon after their labours, means should be taken to satisfy their requirements! Doubtless, under these circumstances, many Fellows who are not members of the committees would be found willing to visit the garden on "inspection day." In any case, let us get to Chiswick and have the opportunity to see and hear what is going on. The Temple Show and the Fruit Show at the Crystal Palace afford opportunities for Fellows and gardeners to meet, but their time is naturally taken up with the shows themselves, and neither the Temple nor the Crystal Palace is Chiswick.

The visits of the Society to some of the great provincial centres seem to have given satisfaction, and indeed anything which is calculated to widen and deepen the influence of the Society in the provinces must be beneficial.

Mr. SHERWOOD's generous offer of a scholarship of £25 for two years in connection with the Society's examination in horticulture is most encouraging, and no doubt it will be confined to actual gardeners, or to those intending to follow gardening as a means of livelihood, else some well trained pupil-teacher or schoolmaster would run off with a prize presumably intended for gardeners only. Indeed, this is one weak point in the present scheme of examinations. Anyone within the limitations of age may enter for the examinations, and in consequence we have boys, and men, and girls, policemen and shoemakers, and we know not who besides, competing one against the other, and with gardeners, amateur or professional. Still more unfair is it that lads from a garden-bothy miles away from a town, or from any centre where they can get instruction, should be obliged to compete with students from Chelmsford, who have an excellent training, and those from Swanley or other colleges.

Last in order among the paragraphs of the Report is one relating to the proposals for duly celebrating the diamond jubilee of the QUEEN'S reign. Various proposals, it appears, have been made, and at length the Council, with at least the tacit assent of Her Majesty, have decided to strike a special medal or medallion, to be called the Victoria Medal of Horticulture, to be awarded "hauris causi in the domain of horti-

culture." If the recipients be carefully selected, and not too numerous, this should be a coveted distinction. It is one which many have rendered themselves entitled to by years of honorary service to the Society, and through it to horticulture. Up to the present, the Society has left it to certain independent "memorial" trustees to award distinctions which would more suitably come from the Society, and even the Lindley Medal for good cultivation has not been awarded for years.

THE additions that have during the past few years been made to our already very extensive list of edible Peas, have most largely been to the medium tall section, which is perhaps the most generally acceptable section cultivated. Varieties that range from 2 feet to 33 feet in height, are excellent for all descriptions of culture. Grown in fields for market picking they are of moderate height, the internodes being short, growth sturdy, and the pods freely produced. When grown in the richest of garden soil and staked, they pod low down, and also to the very top, and therein not the waste, ordinarily of 3 feet, of barren growth which is usually found on tall Peas. So good, too, have been the varieties recently introduced, that all round hard Peas are practically eliminated from lists except for very early purposes in fields; for in gardens the dwarf wrinkled first earlies now have the primary place. It is sometimes remarked that modern Peas have less flavour than was found in the old marrows, such as British Queen, Ne plus Ultra, &c. But much depends who her flavour be confounded with sweetness, for some of the old marrows were rich in sugar, and by many persons regarded as far too sweet. If the more modern Peas be less sugary, that can hardly be termed loss, as there is with many excellent flavour; also with these as with Potatoes, flavour is often through condiments, an added quantity. But whilst such advantages or disadvantages can be claimed for modern Peas, there can be absolutely no doubt but that in the matter of productiveness great advance has been made. It is not merely in the length and in the number of pods that we see this, but where cultivation is even fair, it is seen that these long pods fill well; so that when the best of all tests of productiveness is applied, that of the shelled quantity, it is found that Pea produce is as remarkable as is that of pod. Pea production in the form of new varieties, apart altogether from the stimulus given to it by competitions, has naturally been in the direction of fine pod production, and so long as these pods have been well filled, with not large, but good, soft, succulent Peas, and abundantly set on the plants, there has been great gain. Of that there can be no doubt whatever. Last summer some twenty-five varieties of dwarf or medium height Peas were grown in Surrey, in both light and porous soil, and in stiff loam. In one case the plants were staked, in the other subjected to ordinary field treatment. All were wrinkled Peas with one exception; Princess Royal, once a favourite, second early marrow, grown in this case with Prince of Wales, and one or two other old sorts, to test the merits of the newer ones. In both cases the seed was sown thickly, much more thinly than is the rule in gardens, though not in fields; and one good result was that in spite of the prolonged heat and drought, all did well, and gave capital crops. It is surprising how Peas thinly sown, especially the robust marrows, will

FIG. 21.—NIPPONIA KAWAIIANA VAR. ALBIDA: FLOWERS SNOW-WHITE. (SEE P. 78.)

make side-shoots, and more than compensate for thinness of plants. The laid Peas in the stiff loam, judged by ripe seed production, gave rather the best results; but on the light dry soil the results were more than satisfactory, and none that is classed as first early was sown—but all were of mid-season, and late cropping varieties, the object being to manifest to the surrounding allotment-holders the value of new varieties such as grown, over those in common use, or which run unduly fall. Of these latter the failures to secure crops during the past summer were many; indeed, they would succeed only where there were great depth of soil and ample manure, and abundant waterings were furnished up till at least the month of August. Selections were made of the leading varieties of four prominent seedsmen, and in the result in each case certain selected ones were specially the best, though all were relatively very good. The best two varieties under 24 inches were The Daisy and Dwarf Defiance, both first-rate second earlys for small gardens and allotments. Of those rather taller, a remarkably prolific early one was Senator. This variety attracted great notice, because of its excellent cropping powers, and though not so large as some others, yet it had well-filled pods. Stratagem, Sharpe's Queen, Promotion, Shropshire Hero, Enterprise, Invincible, and Magnum Bonum, the latter having the finest pods, were all first-rate, and seem worthy of wide acceptance, though most of them are largely grown now. Two very superior Peas of medium height grown at Chiswick, and certificated later at the Drill Hall, are Boston Unrivalled, and the Gladstone, the latter apparently a specially superior late variety. Others good later on are Autocrat, regarded as one of the best; and Late Queen. It is thus evident that in the section referred to, we have many excellent varieties.

HYBRID NYPHÆAS.—The illustration (fig. 21) at p. 77 shows another of the fine race of hardy Water Lilies which we owe to the patience and skill of M. LATOUR-MARLAC. In some respects it is the finest of all, the leaves having a diameter of 12 inches. They are olive-green, and destitute of the purplish spots which occur in other varieties. The flowers are pure white. Like the other varieties, this is perfectly hardy, so that it forms a magnificent addition to our gardens. Unfortunately, we do not know the precise origin of these fine varieties, but the ordinary cultivator will think their beauty outweighs all other considerations. Our illustration was taken from a plant growing in a pond at Gunnersbury under the charge of Mr. HUDSON.

LINNEAN SOCIETY.—At an evening meeting to be held on Thursday, February 4, at 8 p.m., papers will be read:—1, "A Revision of the Tribe *Nauclæa* (Nat. Ord. Rubiaceae)," by Dr. G. D. HAYLAND, F.L.S.; and, 2, "A Contribution to the History of New Zealand *Belinodermis*," by W. H. FARQUHAR.

EDINBURGH SCHOOL OF RURAL ECONOMY.—Mr. D. T. FISHER is delivering a course of lectures on "Landscape Gardening" at the Royal Botanic Garden, Edinburgh. The following syllabus shows how the lecturer treats his subject. The object and scope of the science and practice of landscape gardening. Dressing, keeping, and beautifying the surface. Choice and conformation of ground-line. Vital importance of considerable variety and sufficient depth of soil. Preparing the earth for its great artistic work. Drainage, enrichment, sub-cropping, &c. Forms of landscapes. Formal or geometrical gardens and demesnes. Natural, English, or mixed gardens and landscapes. Furnishing and planting of landscapes. Times, methods, materials. Filling in neutrals with Oaks, Beeches, and other trees. Lighting up landscapes

with flowering trees. Planting in shadows with Conifers. Fringing landscapes with flowering shrubs and plants. The "Rosa-rising" of landscapes. The decoration and beautifying of our cities and homes.

ESSEX SCHOOL OF HORTICULTURE.—The *Journal of the Essex Technical Laboratories* (Chelmsford) announces that an advanced course of instruction will be given at the County School of Horticulture during the first three weeks of February; and that a piece of land 3 acres in extent has been secured near Chelmsford for the establishment of a botanic and demonstration garden.

THE NATIONAL AGRICULTURAL UNION is determined to impress upon its Parliamentary representatives the urgent necessity for a new clause in the Finance Act, to abolish the injustice of the Land Tax assessment. In many instances the Land Tax, instead of being diminished by the Finance Act of last year, as it was expected, has been increased. By means of the official organ of the Union, evidence is being collected on the subject, which in due course will be laid before Parliament.

ANTWERP ROYAL HORTICULTURAL AND AGRICULTURAL SOCIETY.—This society, founded in 1825, and which hitherto has organised 165 exhibitions, has lately become incorporated with the Antwerp Royal Zoological Society. Large buildings are to be constructed in the gardens of the latter, to include a *salle des fêtes*, winter-garden, museum, conference hall, and refreshment rooms. The horticultural shows will henceforth be held in the Zoological Society's Hall, the first fixture being July 31 next. Conferences on Zoology and Horticulture will be held at intervals under the auspices of the two Antwerp societies, now so happily amalgamated. *Ch. De B.*

AMSTERDAM.—A *Chrysanthemum Club* has been established in this city on the lines of the National *Chrysanthemum Society*.

GENEVA EXHIBITION.—*Prix d'Honneur* have been awarded to various firms for market-garden produce: to MM. Froebel of Zurich, Bocard and Thibaud of Geneva, for ornamental trees and shrubs; to M. Yachoux, for Roses; to M. Bocard, for cut Roses; to Messrs. Froebel, for new plants and stove plants; to Messrs. Yachoux, for greenhouse plants; to M. Pillet, for bulbous plants; to M. Corveon, for hardy herbaceous plants—the same gentleman also received a prize for horticultural literature and instruction.

SWEET PEAS.—The *Florists' Exchange* for Jan. 2 gives a series of outlines showing the average size and form of the standard in twelve of ECKFORD'S newer varieties. The largest diameter is 38 millimetres (1½ inch about). In form the standard is flat or involute on one or other, or on both margins. The notch at the apex varies in depth, and the short stalk at the base is equally variable.

AT HAYWARD'S HEATH, on the 22nd inst., it was decided to hold a *Chrysanthemum show* there during the coming autumn. It will be promoted by members of the Horticultural Society, but the accounts are to be kept separate.

CHISWICK GARDENERS' ASSOCIATION.—At the usual fortnightly meeting of this body, held on the 21st inst., Mr. S. T. WRIGHT, President, in the chair, Mr. J. HUDSON, Gunnersbury House Gardens, read a paper on "Apples and Pears."

NATIONAL CHRYSANTHEMUM SOCIETY.—A meeting of the general committee was held at Anderson's Hotel on the 25th inst., Mr. E. WYNN presiding; after the transaction of some formal business, the following resolution was unanimously passed:—"The Committee of the National *Chrysanthemum Society* desire to place on record their sense of the loss sustained by the society through the death at Forest Hill of Mr. W. PIERCE, a well-known member, and an exhibitor at the shows of the society. They bear in grateful remembrance his constant endeavours to improve and popularise the section of early-flowering varieties, and the useful additions he

made to the section from time to time." A letter was read from Mr. J. W. WILKINSON, the secretary of the Royal Aquarium Company, stating that the directors would give the same amount of money to each of the four exhibitions as in 1895, and confirming the selected dates of the same. Mr. C. HARRAN PAINTE, the foreign corresponding secretary, laid upon the table the large Gold Medal awarded to the National *Chrysanthemum Society* by the Agricultural and Horticultural Society of Ghent in November last for a collection of cut blooms of English growth taken over by the department, and also the official Certificate of Merit, awarded to a fine bloom of Madame Carnot, in the collection. A report from the Special Classification Committee of Growers was then read by the Secretary, and after some discussion it was unanimously passed, and a hearty vote of thanks was given to the committee for their services. The judges nominated by the schedule sub-committee to make the awards were, with one or two exceptions, elected. Eleven candidates for membership were elected, including three Fellows; and the Dorking and district *Chrysanthemum Society* was admitted to affiliation.

A MEMBERS' DINNER of the Hartlepool and District Gardeners' Mutual Improvement Society was held at West Hartlepool on the 20th inst. About forty persons were present, and the event, which is the first one the Society has celebrated, was presided over by His Worship the MAYOR. The Society is doing considerable service to horticulture in the district, by affording means for the interchange of ideas and practices among its members.

ILEX LATIFOLIA.—From Kilmacnragh we receive specimens of *Ilex latifolia* in berry. It is a fine Holly, which might pardonably be passed over as a Cherry Laurel or a green Aucuba. The globose berries are like those of the common Holly, but smaller and paler in colour.

MR. HUGH FRASER.—The *Edinburgh Evening Dispatch* publishes a photograph of Mr. HUGH FRASER, who is about to retire from the service of MESSRS. MATHYEN & SONS, nurserymen, through failing health. Mr. FRASER has been with this firm during the last forty-eight years, and as a member of the Edinburgh Naturalist's Field Club and Microscopical Society, the Edinburgh Botanical Society, and the Scottish Horticultural Association, is widely known and respected. He is the author of a book upon Conifers and Rhododendrons, published by Messrs. BLACKWOOD & SONS, and has frequently contributed horticultural articles to scientific and popular magazines.

THE LOUGHBOROUGH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION held their fortnightly meeting in the Co-operative Rooms, Woodgate, on Tuesday evening, the 19th inst. Mr. A. HANMERE of Beau Manor Gardens, occupied the chair. The subject-matter for the evening was Mr. POWELL'S "Notes on the Deciduous *Dendrobium*," the cultivation of which was detailed in a lucid manner. The essayist brought the following species to the meeting, viz.:—*Dendrobium nobile*, *D. nobilifolium*, *D. Leechianum*, *D. Wardianum*, *D. Cooksoni*, *D. Ainsworthii*, and *D. splendensissimum*, thus adding much interest to his remarks. Quorn Lodge was long celebrated for its collection of Orchids, but since the death of the late Mr. HOPE, the greater part of the collection has been dispersed; only a few varieties, which are of use as cut flowers, &c., being retained.

ISLE OF WIGHT CHRYSANTHEMUM SOCIETY.—The annual meeting of the Isle of Wight *Chrysanthemum Society* was held at Newport, on Saturday, January 16, 1897. The financial statement showed the Society to have commenced the past year with £23 9s. 5d. The total takings at the last show amounted to £30 7s. 5d., which with donations and subscriptions brought the total receipts up to £93 11s. 4d. The balance remaining for next year is £22 7s. In the election of officers, Sir CHARLES SEELY, Bart., was re-elected President; Dr. GROVES,

E.A., J.P., Chairman; Dr. M. L. E. COOMBS, Treasurer; and Mr. J. TAYLOR, Assistant-Secretary. Votes of thanks were passed to all those who in any way rendered assistance at the last show.

THE RAINFALL AT ROTHAMSTED FOR THE YEAR 1896 was as follows:—

Month.	1896.		1896, more (+) or less (-) than average.
	Rainfall in 1896.	Average Rainfall 40 years.	
	Inches.	Inches.	Inches.
January	1.12	2.45	- 1.33
February	0.59	1.74	- 1.15
March	3.75	1.73	+ 2.02
April	0.95	1.97	- 1.02
May	0.48	2.33	- 1.85
June	2.25	2.41	- 0.16
July	1.27	2.73	- 1.46
August	2.91	2.66	+ 0.25
September	8.08	2.75	+ 5.33
October	1.46	3.19	- 1.73
November	1.39	3.77	- 2.38
December	1.42	2.17	+ 0.75
Total 12 months ...	31.91	28.64	+ 3.27

The total rainfall for the twelve months of 1896, writes Mr. J. J. WILLIS, amounted, according to the gauge of Sir J. B. LAWS at Rothamsted, Hertfordshire, to 31.91 inches. This is 2.7 inches, or nearly 273 tons of water per acre, in excess of the average rainfall extending over a period of forty years. The foregoing data shows that seven months of the year gave less than the average rainfall, whilst the four months of March, September, October, and December, gave a total of more than 20 inches of rain, equal to about two-thirds of the year's fall. The rainfall of 1896 was very similar in quantity to that of 1894, but was very differently distributed over the various months.

UNIVERSITY OF DUBLIN.—The Provost and Senior Fellows of Trinity College, Dublin, have directed that Dr. EDWARD PERCIVAL WRIGHT shall continue to hold the Professorship of Botany in the University of Dublin for another term of seven years, from May 10, 1897. *Irish Times.*

GARDENING AS A REMEDIAL AGENT.—One of the saddest afflictions that befalls humanity, and one of the most trying to the friends and bystanders, is epilepsy. The uncertainties and dangers attaching to it, the frequent absence of all warning, to say nothing of other details which would be out of place here, too often render the sufferer incapable of continuous work. If not so incapacitated, he has, not unaturally, very great difficulty in procuring employment, or it may be is absolutely unable to do so. And yet open air exercise and healthy garden or field-labour are among the most valued means known to physicians of mitigating the disease. With this view, some descendants of the good Samaritan have established a National Society for the employment of epileptics, and a "colony" for the reception of such as are thus afflicted has been founded at Chalfont in Buckinghamshire. Here important work is being carried on, and here, as we are authoritatively informed, the physicians are meeting with success. Gardening operations of various kinds occupy a large share in the treatment, on which account the emjoined letter from the secretary may interest many of our readers.—

"It may probably interest your readers to know that the 'Colony' recently established at Chalfont St. Peter, Bucks, for the employment of epileptics in gardening, farming, and other occupations, has already proved a great success, and is being very rapidly developed. The 'colonists' live in detached houses, each containing eighteen to twenty-four inmates, and several new houses will be erected in the course of the year. Everything that adds to the brightness and attractiveness of the surroundings increases the happiness of the colonists, and indirectly tends to the improvement of their health. Round each of the houses, therefore, will be a small flower garden, and gifts of trees or shrubs would be highly appreciated. Perhaps I may also mention another gift that would be much valued by the colonists, namely, an old wickerette or other vehicle in which, on holidays, they might be taken for drives, and

enabled to see something of the very beautiful country that surrounds the colony. Gifts such as those mentioned, or any others that could be utilised upon farm or garden, should be addressed to the Bailiff, The Colony, Chalfont St. Peter (the farm Road Station), and would be most gratefully received and acknowledged. "I am, &c., "G. PERS GANSELL, "Secretary."

"National Society for Employment of Epileptics," "12, Buckingham Street, Strand, W.C."

THE TRADE OF 1896.—The well-being of the community is so bound up with its foreign and colonial trade, that no excuse need be pleaded for a brief survey of last year's imports and exports, to which once a month for years past the attention of the reader has been directed under the heading of "Stock-taking." Some idea of the vastness of the interests involved may be formed from the fact that, together, last year's imports and exports were valued at £681,729,544, as against £642,573,674 in 1895, or an increase for the past year of some £39,155,870. The figures are enough to take one's breath away. The past year's imports, as will be seen, are placed at £411,807,335, as against £416,080,658, showing a gain of £25,117,077, or over two millions sterling a month. The following figures are those which principally concern us here—taken from the summary table:—

IMPORTS FOR THE YEAR	1895.	1896.	Difference.
	£	£	£
Total value	416,080,658	411,807,335	+ 25,117,677
(A) Articles of food and drink—duty free	149,242,879	148,301,708	+ 941,171
(B) Articles of food and drink—duty-free	25,978,790	25,693,796	+ 284,994
Raw materials for textile manufactures	79,769,681	71,766,939	+ 8,002,742
Raw materials for sundry industries and manufactures	11,921,397	47,240,940	- 35,319,543
(A) Miscellaneous articles	11,367,741	15,066,432	- 3,698,691
(B) Parcel Post	978,191	1,912,348	- 934,157

Looking over the mass of figures in the section devoted to articles of food—duty free, we learn that the total imports of butter from foreign countries and various colonies foot up at £15,344,083 in value; cheese at £4,900,428; eggs at £4,184,567; poultry and game were entered to the amount of £605,458. The value of fruits imported, including Oranges and Lemons, is placed at £5,540,069; but the following little table will be somewhat more explanatory—it gives for the year what we record month by month:—

IMPORTS FOR THE YEAR	1895.	1896.	Difference.
FRUITS, RAW.—			
Apples bush	3,292,262	6,177,142	- 2,884,880
Cherries "	19,632	219,267	- 199,635
Plums "	40,468	360,246	- 319,778
Pears "	667,146	483,823	+ 183,323
Grapes "	866,287	885,254	- 18,967
Unenumerated "	1,249,363	1,427,165	- 177,802
Onions "	5,744,798	6,085,505	- 340,707
Potatoes cwt	5,788,139	2,211,627	+ 3,576,512
Vegetables, raw, unenumerated value	41,271,269	41,284,631	- 13,362

The value of articles of food, dutiable and duty-free, is, as will be seen, £171,995,414—a very large proportion of the total imports, and full of encouragement to those who maintain that it is possible to retain at home much of the money sent out of it for foreign provisions. As to—

EXPORTS.

the total for last year is £239,932,269, as compared with £225,890,016 in the preceding year—showing an increase of £14,042,253—an amount which, without doubt, would have been doubled had politics been less prominent in many parts of the world. The gain in metals and articles manufactured therefrom, except machinery, increased by £1,686,315; articles manufactured, and partly so, viz., yarns and textile fabrics, increased by £3,976,277; machinery

and millwork have had a gain of £1,880,377. It is worthy of note that apparel and articles of personal use put on £1,166,215 extra. But no more examples need be quoted as to the soundness of the export trade in articles of British and Irish manufacture. In all of the above there is, we submit, a lesson for all the world—foreign and colonial—that furnished by free trade; herein is to be found the greatest good for the greatest number—here, more than elsewhere, can the best man win.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—A special meeting of this Association was held at Newport on Saturday last. Dr. GROVES (Chairman of the Association) presided over a very good attendance of members. A unanimous vote of thanks was accorded C. L. COACHER, Esq., the new manager of the Isle of Wight Central Railway, for his efforts in assisting the Association in the promotion of agriculture and gardening, the principal industries of the island, by reducing the rates of carriage of garden and farm produce to London and other places on the mainland. It was also resolved that the association should be affiliated with the Royal Horticultural Society. A sub-committee was appointed to draw up a scheme for the re-organisation of the association. By the combined efforts of the market gardeners in the island, and the members of the above association, much good can be done towards developing its horticultural and agricultural industries.

GINKGO BILOBA.—A Japanese botanist—Dr. HERASE of the Botanical Institute, Tokio—claims to have discovered spermatozoids in this plant; and another professor at the same University professes to have found similar bodies in *Cycas revoluta*. If these very remarkable discoveries are confirmed, an important link between the Conifers and the higher Cryptogams will have been brought to light; but for the present, it is safe to await the confirmation of these researches.

NEW PUBLICATIONS.—*The Forester* (PRINCETON, N. Jersey), which now becomes a monthly journal, under the editorship of Mr. JOHN GIFFORD.—*A Manual and Dictionary of Flowering Plants and Ferns*, by J. C. WILLIS, M.A., Director of the Royal Botanic Garden, Ceylon (CLAY & SONS, Cambridge University Press Warehouse, Ave Maria Lane).—*Fruit Culture for Amateurs*, by S. T. WRIGHT (L. URCOTT GILL).—*Diseases of Plants induced by Cryptogamic Parasites*, by Dr. KARL FRIEHEIHER VON TOUBEU; English edition by WILLIAM G. SMITH, Ph.D. (LONGMANS).—*An Illustrated Flora of the Northern United States, Canada, and the British Possessions*, by N. L. BRITTON, Ph. D. & Hon. ADDISON BROWN (New York Scribners).—*British Moss Flora*, Part xviii., by R. BRAITHWAITE, M.D. (303, Clapham Road).

HOLME LACEY, HEREFORD-SHIRE.

THIS, the seat of R. Oliverson, Esq., is a fine old place, standing amidst beautiful scenery, and renowned for its extensive bedding-out. About 50,000 plants are annually displayed, and through the generosity of Mr. Oliverson, the public are privileged to visit his beautiful gardens. The mansion is about half a mile from Holme Lacey station, and for nearly the whole distance finely-clipped Holly hedges line either side the road. Next to strike the eye are massive Yew hedges in perfect health, and clipped to perfection; and the Yew trees are cut annually by that very useful implement, the French pruner, and pruned and clipped into a variety of forms, some quite novel. There are, too, some fine Conifers to be seen.

Just now in the hall are some excellent groups, consisting of *Chrysanthemums*, *Richardias*, *Euphorbias*, *Azaleas*, *Primulas*, *Lily of the Valley*, *Cyclamens*, &c., and in the houses and frames there are plenty of plants to continue the display. The *Richardias* in 14-inch pots are extremely fine, both in growth of leaves and pathos. I found these were reported as soon as the leaves had died down. *Cyclamens*, Veitch's strain, were carrying as many as thirty six flowers, and

plenty more still to open. The *Euphorbia* (*Poinsettia*) had bracts which measured 18 inches across.

In the greenhouse there is a fine show of flowers, and a plant which deserves to be much more grown—*Stigmaphyllon ciliatum*—which should be seen in the best collection of climbers. Its flowers resemble those of *Ocimum flexuosum*, and the plant is very free-flowering.

The Orchid-house and stove combined contain a nice healthy collection of plants; in flower were *Calanthe Veitchii*, *C. vesitata*, and *C. oculata*; *Phaius grandiflorus*, *Dendrobium Phalenopsis* *Schroderianum*, and *D. nobile* *Wardianum*. The old conservatory is a home for *Camellias*, &c.

The five vineries contain Vines in perfect health, although a vast number of plants are grown in them to keep up the heavy demand for plants and flowers in the dwelling. Mention may specially be made of *Smilax*, growing near the back wall, and trained up pieces of string; and of large healthy batches of *Freesia* and *Lachenalia triolor*.

The Peach-houses are in fine form, the trees grown on the extension system, and some of the trees bought two years ago, look fully ten years old, and have borne heavy crops of fruit. Under the back-roof of the three-quarter span Melon and Cucumber-houses are well-grown plants of *Stephanotis floribunda* and *Allamandas*; and the stage beneath carries well-grown plants of *Adiantum Farleyense*, *Eucharis grandiflora*, and *Spiraea japonica*, with blossoms just opening. The front portion is devoted to batches of early-flowering plants, bulbs, &c., and to plant-propagation purposes till the Cucumber and Melon plants are ready to plant out.

The kitchen-garden walls are well furnished with fine trees, and the quarters well cropped with vegetables, and here, as elsewhere, careful cultivation is exhibited. I learnt that after the first Peas are picked and over, the haulm only is cleared away, and Runner Beans are dibbled in, the plants affording fine late gatherings, thus saving the time of staking and digging at that very busy time of the year. I noticed in full flower a fine plant of *Chimonanthus* fragrans on a south wall, a beautiful shrub that should be more commonly grown than it is. The general keeping of the garden reflects great credit on Mr. Randall, the head-gardener, W. E.

NEW INVENTION.

We have had submitted to us for examination the "Clozone" Orchid-pot, brought out by the Messrs. Rosher, of Ipswich, designed to help the gardeners in the successful culture of Orchids and other epiphytal plants. "Air plants" demand plenty of humid air, from which their aerial roots derive necessary nourishment, while the base of pseudobulbs from which springs the young growth or leads, must be well above the inimical influence of soured or saturated soil. Perfect drainage is the *sine qua non* of success. No crocks are necessary in potting, thus saving time to the gardener. A layer of moss, a few nodules of charcoal, peat, and sphagnum placed in the lower part of the pot, and secured by wire or raffia to the raised centre, on the top of which the Orchid is fastened. Under the hollow, perforated cone the air passes freely, and conduces to the health of the plant, causing the emission of strong and healthy roots, which burrow among the soil, from which all superfluous moisture (after watering by immersion or otherwise) rapidly drains away. The smaller sizes are made to suspend from the roof of the Orchid-houses, are light, and pretty in form, and ornamental when planted; they are, too, most handy to water by plunging. The larger sizes for standing on the stages are mounted on small feet of clay, to admit of the free passage of air and rapid drainage. For the preparatory potting of newly-imported Orchids, as well as for maturing the growth of established plants, these "Clozone" pots will be found useful. Fresh peat and sphagnum can be added without undue disturbance or breakage of tender roots. The pot is well designed to meet the conditions above described.

CULTURAL MEMORANDA.

LUCULLIA GRATISSIMA.

This is a very handsome plant, amenable to pot culture, but thriving best in a bed or border in a conservatory, where plenty of room can be afforded it. The rooting medium should consist of fibrous loam, peat in equal parts, silver-sand, and plenty of sandstone broken into small pieces, also a small portion of lime-rubble. On the occasion of a recent visit paid to Firbeck Hall, South Yorkshire, the residence of the Rev. H. G. Jebb, I observed in the large conservatory a specimen which perhaps has no equal in the country. This was planted about the year 1880, and at the time of my visit it was carrying between 500 and 600 heads of fully-expanded flowers. The flower heads contain numerous flowers, one of two fine heads given me by the gardener being found to consist of no less than 106 fully-open flowers (fig. 22.) It is surprising that this beautiful *Himalayan* plant is not more common in gardens, seeing the ease with which it can be cultivated, and the comparatively flowerless portion of the year during which its flowers appear. *H. M., Lancashire.* (Like the beautiful so-called greenhouse *Rhododendrons* raised in such numbers by Messrs. J. Veitch & Sons, the plant requires a temperature during winter, spring, and autumn, intermediate between that of the greenhouse and the stove. In summer, artificial heat is scarcely required. Our illustration is taken from a plant in the collection of J. Hope, Esq., Belmont, Millothian, Ed.)

SCOTLAND.

GLASGOW PUBLIC PARKS.

THERE are fourteen public parks in and around Glasgow, covering in the aggregate about 1000 acres, which have been acquired, not counting the cost of "Glasgow Green," at a sum verging upon 2450,000 of these no fewer than eleven have been purchased since 1890, and laid out and dealt with according to the respective needs of the locality. Like every manufacturing centre of importance, tree and shrub life suffer greatly from smoke and other impurities, and hence much of the space is under grass, with plantations for margins; and where the people mostly congregate, bedding out is introduced on a large scale—bulbs for spring, and miscellaneous plants for summer, involving, of course, considerable labour. The opening of the Botanic Gardens to the public is a great boon, and one that is greatly appreciated; and the principal parks, such as Kelvin Grove and the Queen's Park, are splendid examples of decorative and ornamental gardening. The lands of Campbhill, which are adjacent, and form a connecting link with Queen's Park, add considerably from a woodland point of view to the people's estate, there being some fine specimens of timber trees about it which are carefully conserved, and the walks and drives are broadened to suit city life.

An important and rather unusual feature that has been introduced since Mr. James Whitton's appointment—which, by the way, is a popular one in every respect—in the erection of a range of glasshouses for supplying not only the needs of ornamental summer gardening, but for meeting the demands made upon the superintendent for plants for the decoration of the City Hall on all important occasions, and for the many rising institutions which are kept up by the charity of opulent citizens. There is a block of ten houses, five on either side of a spacious corridor, with an ornamental dome. The corridor itself is 174 feet long, 24 feet wide, and 13 feet high. The houses, which stand at right angles, are each 89 feet long, and vary in width according to the material ground within. These houses are thrown open to the public, barring two set apart for propagating purposes. During my visit the *Chrysanthemums*, which are galore now-a-days, and are about the cheapest and showiest furnishing-material that can be grown, were very gay, one almost felt a relief turning from the masses of unkempt Japanese—"toozie," as the Scotch say, beyond measure to the quite beautiful flowers of such

a variety, for instance, as *Mary Anderson*. There is a nice set got together of the more useful decorative Palms—*Kentias* and of the *Dracenas* and *Crotons*, the stock of which is large, and always a pleasure to look upon. *Camellias*, too, were noticed in large numbers, and this is a place to recall people's attention to a class of plants now-a-days undeservedly neglected. The graceful panicle *Imnea elegans* is grown by the hundred, as is the useful *Francoa ramosa*. *Lapagarias* and *Stephanotis*, and some of the showier stove-plants, *Sikkim* and hybrid *Sikkim Rhododendrons* are grown in quantity, chiefly for forcing out flowers; and then the stock of bedding plants is large and varied. Two or three of the houses are all but filled with Orchids of temperate and tropical climates. I was glad to observe a fine and varied lot of *Mastodermis*, in beautiful health too, one of the very best of the *Haryana* type, probably *M. H. splendens*. There is nice young stock of *Odonotoglossum crispum* and its congeners. *Cypridiums* were bright and beautiful, especially the forms of *C. insignis*. *Cattleya labiata*, now one of the cheapest and most celebrated of the family, was in good flower. A great number of others in variety were coming along. *Nepenthes*, too, and quantities of *Ferns*, and the useful prostrate *Asparagus* were noted in two or three varieties. The stock of *Eucharis grandiflora* and *Pancratiums* is getting considerable, and the plants show vigour.

There is a very large Winter Garden in course of construction on Glasgow Green, where the giants of vegetation will be easily accommodated. Altogether, public gardening in the "Second City" is broadening in its influence, and although the people's purse are expended a little more freely than heretofore, it is not in my belief without suitable returns in the matter of healthful recreation and enjoyment. *J. A.*

HOME CORRESPONDENCE.

PEARS OF GOOD AND BAD QUALITY.—In reply to Mr. J. Easter's inquiry of the variety *Conseller de la Cour* in a recent issue of the *Gardeners' Chronicle*, I find that this variety does well with me as a pyramid, bearing fine melting fruit, but of a colour that is not very attractive, being of a greenish-yellow when ripe, which would doubtless go against it as a market fruit. The soil here is a sandy loam, with a mixture of clay, and being rather light, it suits Huxley's Victoria Pear. *G. T., West Park, Salisbury.*

—As no one has replied to Mr. Easter's inquiry (*Gardeners' Chronicle*, p. 48) respecting the quality of *Conseller de la Cour* Pear in the south, I would remark that with me it is one of the best October and November Pears; flavour good, size large, and the tree generally bearing good and regular crops; it is also a very good grower. I have the variety as large pyramids on the Quince stock. If allowed to over-crop, of course the quality of the fruit would be impaired. It succeeds Louise Bonne of Jersey. Louise Bonne, *Conseller de la Cour*, *Duycenck du Conice*, *Hacon's Incomparable*, and *Joséphine de Malines* on large pyramids are my most useful Pears. *James John Easter, Stanmore, Middlesex.*

THE FUTURE OF THE CYCLAMEN.—A few years ago a Cyclamen was exhibited at one of the meetings of the Royal Horticultural Society, with an inconspicuous white crest running up the centre of each petal. One of these blouses was illustrated in the *Gardeners' Chronicle* at the time, and the block was reproduced a few weeks ago in illustration of an exhibit by Messrs. Hugg Low & Co., at the December meeting held at the Drill Hall. The old block, however, did no sort of justice to the advance made by Messrs. Low & Co., and at my request the firm kindly supplied me with several typical blouses. One of the best of these is shown (fig. 183), where it will be seen that not only has the crest growth now become in some blouses highly developed into a series of white crests one above the other, but the petals show bold outgrowths towards the base of the flowers, and exhibit slight indications of notching or fringing. On a very careful examination of the compound fringe, a slight twist can be detected in each outgrowth after the manner of the petals. On looking to the calyx, faint indications of notching can be detected in some examples. In the Primulaceae the natural order to which the Cyclamen

belongs, the stamens are not alternate with the petals, as is usually the case in other natural orders of plants, but opposite to the centres of the petals. The future of the florists' Cyclamens must be, therefore, as sketched at C, a large number of petal out-crowths lapping over each other and not alternate. *W. G. Smith.*

A HYBRID CINERARIA.—I can fully bear out Mr. Harrow's statement respecting the *Cineraria* mentioned by him in last week's *Gardeners' Chronicle*, p. 63. When on a visit to the Sheffield Botanical Gardens the first week in November last, I had the pleasure of seeing the plant referred to, which was then in full bloom, and I was much struck with its beauty, and what I may term, its utility, as it is of a more decorative value than the ordinary garden *Cineraria*. The habit of the plant is elegant, and more branched, the leaves not so large, and the peduncles longer, and there being rather wavy make the flowers very suitable for cutting. The flowers are self-coloured, bright, and pleasing. It is an unfortunate feature

running a little. The potting is done with moderate firmness, the compost being neither too moist nor too dry. No water should be applied before the pots ring well when struck with the knuckles, but syringing them over-head as may seem necessary in dry weather. Cyclamens grow freely during the summer in cool frames on a north aspect till September, when they should be removed to a south aspect, where they can remain until the middle or end of October by covering the plants at night to ward off frost. After this date they should be removed to a temperate-house, and placed close to the glass; and if stood on inverted pots over moist ashes, all the better. By October the pots will be filled with roots, and weak liquid-manure afforded twice a week will assist them very much. I have now in my charge over 150 Cyclamens which came from Sutton & Sons, and which are opening plenty of fine flowers. Cyclamen roots are very strong, and I consider that pretty firm potting is desirable. If my method of managing old cornus is acceptable to your readers, I

new strain—one was for the petals to become decidedly short, broad, and rounded, rather than oblong-spatulate, as in the case of the type; and in a few cases they were some way towards flattening-out, though remaining saucer-shaped. The strain was designated *Papilio*, which is scarcely a correct and appropriate one. The most attractive variety was one in which the petals were bright deep rose, with short, broad, rounded petals slightly fringed, opening out in the form of a single rose, and reflexing; another was white, saucer-shaped, and the large petals much fringed, but here the tendency was to incurv rather than reflex. Another white was of the same size and form, but the centre was bright crimson, as in the case of the mouth of the corolla of the improved form of *C. persicum*; but this was not so much fringed on the petal edges as in the case of the previous one. Another had pale rose blossoms, with a rose-crimson centre, the petals fringed and incurving. Another blush-tinted variety had the fringed petals

FIG. 22.—LUCULIA GRATISSIMA. (SEE P. 80.)

that this species fails to produce seed, it being such a valuable addition to winter-flowering plants. It appeared to be very free and continuous flowerer. To work up a stock from cuttings sufficiently large to put on the market must take a long time, notwithstanding its free-rooting properties. *J. H. W.*

CYCLAMENS NOT OPENING THEIR FLOWERS.—I read with attention the articles which have appeared on this subject, but without discovering anything novel in the method of cultivation pursued by the writers. Your correspondent, "C. B. W.," did not state whether his Cyclamens were seedlings or old cornus; but with both, good drainage is an essential point. I have grown good numbers of Cyclamens, although I am but a working gardener, and I never had plants which did not open their flowers properly. The kind of compost I generally made use of consisted of decayed fibry loam two parts, no matter what colour, but preferably that from stiff land, decayed leaf-mould one part, coarse silver-sand one part. I make the drainage perfect, at the same time letting it take up as little space as possible; or the crocks a small quantity of moss is placed, and above this a few rough pieces of the loam,

will write again when the flowering-time has passed. *J. L., The Woodlands, Staffs.*

THE WEATHER IN CUMBERLAND.—The weather in these parts has been very severe lately, and boisterous snow-storms have been experienced almost daily. The neighbouring hills are clad with snow, and we have a covering 6 inches or more deep all round. Our thermometer on the night of the 17th registered 24° of frost, and nightly we have had 8°, 10°, and 12°; registering on the 23rd, Saturday night, 29° of frost. *Arthur Smith, Eden Hall, Longworth.*

A NEW STRAIN OF CYCLAMEN PERSICUM.—That there will be differences of opinion as to the value of the strain of *Cyclamen persicum* Mr. de Langhe, *lieu de Constantinople*, Brussels, exhibited at the meeting of the Royal Horticultural Society on 12th inst., there can be no doubt; but that they represent something quite distinct and out of the common (see fig. 19, p. 71). The possibilities of development in them should lead them to be regarded with favour rather than with disfavour. There could be observed two tendencies in the

hooded with rose; in this case the petals were reflexing, and appeared as if they would eventually assume the normal shape. Another, and one of the most promising, had but one flower expanded, the ground was blush, but the central stain of bright crimson was much diffused; the much-fringed petals were bluish-white on the edges. Some salmon-tinted varieties were diversely and irregularly shaped, but all more or less coloured about the mouth of the corolla. The Floral Committee did wisely in giving an Award of Merit to the strain because of its distinctness. *R. D.*

GRAPES AT EXHIBITIONS. In regard to this controversial matter, Mr. Kirk, I think, must be aware of the fact that I acted as a censor at the exhibition indicated, and had three hours' work among hardy fruits. The committee of management knew well the sad circumstances which necessitated my hurried exit from that fine show, and I should have been excused performing my duty had I desired it. I was therefore prevented from making a careful inspection of the Grapes. As to criticising the awards of the Royal Horticultural Society at the Crystal Palace, this is a statement which is untenable, as neither in

thought, word, or deed, have I disparaged the awards of the judges on this occasion. I, however, fear that we are not likely to get rid of the friction—so common at exhibitions—if horticultural societies do not submit something definite for the guidance of judges and exhibitors alike. *M. Temple, Carron, N.B.*

THE NEW "BLUE" PRIMROSES.—The variety *G. Wilcox* is a beautiful hardy plant for the spring garden, and I send a few flowers for your inspection of different shades of colour from seedlings. I obtained a packet of seeds in February, 1896, and sowed the seed, as soon as received, in a mixture of loam and leaf-mould and sand, in a pan which I placed in gentle heat. The plants (thirteen) came up, and in the month of May I potted them off into 60's, and placed them in a cold pit; in July they were shifted into 32-pots, and these plants are large in size and in full bloom, all but one being of blue or purple shades of colour. They form a pretty addition to early spring flowers, and as the plant is readily increased by division after flowering, it makes a useful plant for the spring garden. Seeds may be sown as soon as ripe. [Pretty shades of colour, but certainly purple—*not blue*. Ed.] *Wm. Smeath, The Gardens, Basing Park, January 11.*

FORCING RHUBARB.—Mr. Wythes, in his note on this subject, appears to forget that Rhubarb is, rather should be, grown to eat. My own experience with forced market Rhubarb is that it is bitter and unpleasant. Varieties are grown which are really unfit for table use, and in my own experience many families have discontinued its use owing to the uncertainty as to what they will get. For a first early of the only variety we have found worth growing is *Linneus*, which Mr. Wythes does not even mention; and after a long and mostly unpleasant experience, we now grow only *Linneus* and *Victoria*, but we do not grow for market, and therefore flavour and quality are of importance. *Thos. Webster, 47, Clapham, Chelsea.* [Our own experience is, that the smaller the Rhubarb-stalks, and the poorer the land on which it is grown, the better is the flavour. Ed.]

THE LATE MR. JAMES WEBBER.—Your correspondent, "A. D.," p. 19, wrote in graceful terms of the late Mr. J. Webber, every word of which I fully endorse, having known him for 40 years, and as a gentleman, knowing him otherwise than simply as a successful market salesman. Doubtless he did much good to the gardeners whom he came into contact with, both by his lessons on the packing of soft fruits, and by the offering of substantial prizes for the best methods of packing. He originated, and carried on single-handed for several years, those valuable object-lessons which greatly improved the methods of packing in general use, and which, had not troublesome times overtaken the Royal Horticultural Society, would, very probably, have been taken up by the exhibitor that they had been so delivered. Three judges were appointed—one a wholesale market man, a retailer, and a gentleman's gardener, South Kensington being the point of rendezvous. Being then in charge of a dual gardening establishment whence nearly all the produce was sold, I entered the competition, and was rewarded with the much-coveted honour, which everybody regarded as the blue ribbon of the season. The fruit afterwards was sent on to Mr. George Monro in the usual way, and realised a high price. Mr. Webber kindly criticised the weak points of the methods I pursued, and gave me some valuable hints, which I utilised, and won in the next year's contest. Circumstances afterwards prevented my competing again, and Mr. Coleman and others took up the running. After my first success, I offered to stand out, but Mr. Webber would not hear of it, and particularly wished my method to be shown as an example of good packing for market. Clean, sweet moss was the chief packing-material used; and even now it is hard to beat it, for when well prepared its elasticity is perfect. Mr. Webber condemned cotton-wool, bran, &c., and always maintained that the cost of the packing-material was of

the greatest importance, it being seldom returned to the sender; and there was no wood-wool in those days, and now-a-days there does not seem to be time to prepare the moss. I have used moss for fruit-packing for the past thirty years without having a complaint; of course, it was well prepared, beaten and teased, and put away in bags when in a quite dry state. Mr. Webber's philanthropy in regard to the gardening charities, it is to be hoped, will be indicated by other Covent-Garden salesmen. *W. Cramp, Malthesfield.*

WOOD-ASHES AS A MANURE.—Mr. T. H. Smith, in his letter on the above subject, overlooks the most important point I raised, i.e., that the dust-ash of coal should be identical in composition and properties with the ash from wood; and if this is the case, hundreds of thousands of tons of this, which could be collected at a very small expense, are annually thrown away. Since my first letter, I have obtained analyses of many samples of coal-ash, but they vary so enormously, that it appears to be difficult to get at an average value, some samples being almost worthless, whilst others are very valuable, judging by their chemical composition. There are many manufacturers in this country where from five to fifty tons of fine coal-ash are made every week; and this could be had for little more than the cost of screening, which would not exceed 1s. or 1s. 6d. per ton. The experiment should be worth trying on a fairly large scale. *Thos. Fleet-her, Groppehall, Cheshire.*

FERDINAND VON MUELLER.—The news of the death of Sir Ferdinand Von Mueller came to me just as I was preparing to send him freshly-ripened seed of *Elymus araneus*, which, after reading his success with *Amphiphila*, I was about to ask him to try; having ascertained that the herbivores of the *Elymus* are freely eaten, and, to all appearance, liked by the horse, it would have many advantages over the *Amphiphila* in the production of food, as well as in its birding roots, and although the appearance and harshness of the foliage may seem unlikely, yet it is noted by Parnell that the *Elymus* contains more sugar than any other British grass, which may be a reason for the horse looking for more when it is offered to him. The last letter I received from Sir F. Von Mueller contains a hint of the probable occurrence on our coasts of an overlooked plant, and its entire contents are just in the style he usually employed: "Briefly of the enthusiasm which carried him through the work he accomplished, and built up his own monument. *William Mitten.*"—"It was most kind of you, dear Mr. Mitten, to send me the large number of Mosses and their allies, by which the collection here in the two herbarium halls (containing nearly a million sheets) becomes so much enriched, and where, so far as human foresight goes, your authentic specimens will be utilised through centuries to come." The Rev. Mr. Powell's collection has a special interest; he showed it to me when we were in England very many years ago, the specimens then to be taken to you. As I have explored through the whole Austral Alps, I am much interested in what you say about your last alpine tour. As you doubtless are conversant also among British and other Phanerogams, may I direct your attention to the probability of *Kochia hirsuta* occurring also on British shores intermingled with *Suaeda maritima*. As the northern forms which I know from Schleswig, [they] are often almost glabrous, [and] are easily passed as *S. maritima*, but generally some hairlets (spots) can be observed in the axils of the leaves, and the upper part of the stem is so rarely turned spirally. Of course the embryo of the two plants is very distinct. Are you sure, that of the numerous mosses which you examined so kindly for us here, a sufficiency is left for your own herbarium? I will keep this, sending for awhile together, so that any specimens particularly mentioned can still be shared by you. Have you kept a record of the localities? If so, such would be well worth publishing in one of the home periodicals, as our knowledge of the geographic distribution of Australian Evasculares is still very imperfect. Let me hope you are happy and well, and will long yet enjoy the triumph of being identified with the moss-dora of the whole world.—Ever respectfully and gratefully yours, *Ferd. von Mueller.*"

GRAPES AT PENRYN CASTLE, BANGOR.—It seems to be the prevailing idea with gardeners that the best Grapes are to be found only at horticultural exhibitions. Fortunately, this is not entirely the case; and at all events, anyone calling, as I did recently at Penryn Castle, will find the reputation for good

Grapes, for which Penryn gardens are famed, well sustained at this season. Here were to be observed bunches of Muscat of Alexandria weighing from 3 to 4 lb. each, with large bright amber-coloured berries, the bunches perfect in symmetry and finish. *Lady Downes'* Seedling was equally good of its kind, berries enormous in size, showing the thinning had been properly performed. An agreeable surprise was to find the new Grape, *Lady Hutt*, in such fine condition, the vine carrying fruit being inarched on to *Lady Downes'* Seedling. The bunches of this variety weighed from 2 to 3 lb. each, with large globular berries, white-green in colour, perfect in finish, plump and fresh, and looking as if they would keep till March or April. This is undoubtedly the finest flavoured late-keeping white Grape in existence, and their condition was a proof that whatever Mr. Speed takes in hand is done well. The whole of the vintages at Penryn were planted thirty or more years ago, and it is a marvel that such high quality in the Grapes is so long maintained. The system followed is not half-hearted extension, followed by severe disbudding, nor is anything sacrificed to appearances. The growing of the foliage, as well as overcropping are most carefully avoided, and the borders come in for a large share of attention; and in the work of renewing them more sharp grit is used than was formerly the case, the better to promote the porosity of the soil when the fibre of the turf soil used decays. Still, no loose, light, or spongy borders are tolerated. *W. Cramp, Malthesfield.*

CEDRUS DEODARA.—I have been much interested in reading the notes on the above variety of Cedar, but owing to rheumatism in my right arm, I have been unable to use my pen. Had I been able, I would have written ere this, as I consider far too little is written in the *Gard. Chron.* about five varieties and species of trees. In regard to this Cedar, I must say that the variety as introduced in the year 1831, and grown and sold by the thousand, is, I consider, a very uncanny tree, particularly as a timber-tree. I have seen it growing nearly all over England, and in several parts of Scotland; and, as compared with the Cedar of Lebanon and many other fine Conifers, it is of very little use. The late Mr. Anthony Waterer, who was one of the best judges of a garden, told me, knowing the tree, that the variety "Allury" like water, and he asked me what I thought of the Deodar? My answer was, "No good," to which he responded, "You are quite right." But what I wish to say now is, that I believe the true Indian Cedar was introduced not in 1831, but two centuries earlier. This tree is quite distinct from the *C. deodara* of to-day, differing also from the Lebanon Cedar. Several Cedars are growing here, and they are all called Lebanon Cedars, although they are quite distinct from the ordinary Cedar of Lebanon, which cannot be mistaken, its distinct tabular form of branches making it conspicuously different from any other kind of Coniferous tree. The tree of which I consider to be the true Indian Cedar has an upright habit of growth. Three examples here are more than 100 feet in height, with trunks which have a circumference of 15 feet; whereas the Lebanon Cedar runs 70 to 80 feet in height, and 11, 12, and 13 feet in circumference. Some of the readers of the *Gardeners' Chronicle* will ask who introduced them to this country? My answer is, who can name the introducer of the first *Cedrus Libani* to this country? Certain it is, that long before the Royal Horticultural Society was ever seen here at Douglas, Lobb, and others, saw the light of day, many of our finest kinds of trees were introduced from abroad, although little is known of the actual introducers. Mr. Wiles, Unsted Park, Godalming, writing in the *Gardeners' Chronicle* of December 19, 1896, says, the Deodar can be seen at Peper Harrow Park "of great age and size." This will I think help to bear me out, that there are to be seen the true "Indian Deodar, a tree quite distinct from the one known and grown in our nurseries during the last forty years. In conclusion, I beg to say that I have never seen the Cedars at Peper Harrow Park." *J. C. Louch, Albany Park Gardens.*

PARENTAGE OF SOME VARIETIES OF THE ROSE.—I read with great interest Dr. Williamson's notes on Roses, but in those upon the "Parentage of Roses," appearing on p. 56 of the present volume, there is an error which should not go uncorrected. He is evidently confused with Therèse Levet and Etienne Levet. Therèse Levet (H.P. is *syn.* with Madame Louis Leveque H.P.), a seedling from Jules Margottin in 1874; but it was not the parent of Duke ofife. Were it not that your corres-

pendent writes that Duke of Fife was obtained from Thérèse Levet, and the last-named from Jules Margottin, I should have thought it a printer's error in substituting Thérèse for Étienne; Étienne Levet, a totally distinct Rose, being the parent of Messrs. Cockers' Duke of Fife. The growth, as well as the raiser's claim, confirms this in every way. There is a Tea Rose under the name of *Souvenir de Thérèse Levet*, introduced by Léçqne in 1839, and also a Tea variety named *Madame Louis Léçqne*, introduced by the same raiser ten years later. When naming those raised by the late Henry Bennett, Dr. Williamson says, "all of these have almost ideal characteristics; they are vigorous (italics are mine), in habit, &c.;" if *Cleopatra*, Princess of Wales, and Princess Beatrice are vigorous with him, it is an exception to their general habit. I doubt if even the Rev. F. Burdaise, the grower of the beautiful *Cleopatra* exhibited at Windsor in the Queen's Cup class some few years back would venture to call it anything but a moderate grower. Indeed, I understood him to say it was difficult to find the plant afterwards. There was no doubt about the bloom, as all who saw it will confirm. *Le Rais* is an old favourite of mine; it was sent out by Lafay in 1843-4, and under the name of *Reine du Midi* by Roland in 1879, and is also known as *Reine des Français*. A. Piper.

CUPRESSUS MACROCARPA.—In answer to the enquiry of "F. M." in last week's *Gardeners' Chronicle* about the *Cupressus macrocarpa* that were planted here forty years ago, he is glad to know they are still there, and are now about 40 feet high, but they have never recovered from the serious damage done to them by a continuation of cold, violent winds about three years ago. They were beautiful specimens twenty years ago. It is one of the most beautiful of ornamental evergreens, and of remarkably rapid growth. It is quite hardy here so far as frost is concerned, but must not be exposed to high winds. I planted a quantity of them in the "Long Walk" here (which "F. M." knows well some years ago, and they are now beautiful compact specimens, thickly clothed with foliage of a bright green colour. Perhaps "F. M." will remember another tree planted by Mr. Moore at or about the same time as the *Cupressus*, namely, the Chinese Juniper, which also stands on the lawn in front of the plant-houses; it is now 20 feet high, closely branched from the ground to the top, and with its bright catkins in summer is an object of much beauty. I only mention this to show how well they do planted on the whinstone rock, with only 6 inches to 15 inches of soil to grow in; and in very dry summers the lawn is always burnt up, which once shows that the Juniper will not stand any undue accumulation of water at the roots. David Inglis, Horlick Hill Gardens, Lezbury.

LADY HUTT AND APPLEBY TOWERS GRAPES.—In your issue of January 16, Mr. Lambert refers to these varieties as having seen them here in 1895. I am pleased to say they were better in 1896 than when he saw them. The best samples of Lady Hutt were grown on a rod grafted on a Vine of Golden Queen, and these Grapes were of a bright yellow colour, and of very good flavour. Grafted on White Tokay they were not quite so good either in colour or flavour. On its own roots, and also grafted on the Black Hamburgh in a later house, the fruit was ripe about October, and were of the usual greenish colour, of which complaint is so often made; neither were they so good in flavour, although, had they been earlier ripe, they might have been better in both respects. I am rather partial to this variety; at the same time, I think that it is not so good in flavour here as Mrs. Pearson, and I question very much if it will keep much longer than that Grape. Appleby Towers, I like the better of the two. I have it on its own roots, grafted on Alicante, Gros Colman, and Lady Downes', and from the latter I have had the finest bunches. I like it better as a keeper than Alicante, but it requires severe and careful thinning, for if at all crowded in the bunch, it is very apt to damp in the centre of the bunches. In point of flavour it is here a little superior to Black Alicante. I bought a few nice bunches of it last week that I think will keep well till the month of March is out. The foliage here of a beautiful light red colour. But for shaking hands with the new Grapes coming in in the months of May and June, which we have done here for many years, we must still depend on Lady Downes' Seedling, an old and well-tried friend to many a gardener who has to keep up a supply all the year round; for it is still the best keeping variety that we possess. J. Wallis, Kedge Hall Gardens.

— It is now some three years ago that I grafted a scion of Appley Towers on a Vine of Black Hamburgh, growing in our late vinery. I have gathered fruit from the graft for the past two seasons; last year it carried six bunches, two of the largest weighing between 3 and 4 lb. each. Two smaller bunches I exhibited in the "Any Variety Class" at the Shrewsbury Show, taking 3rd prize, being beaten by fine examples of Madresfield Court. Then again, the 3rd prize bunches beat fine bunches of Gros Maroc in the same class. I consider Appley Towers possesses many good qualities, and as it gets better known it will be more extensively cultivated. It resembles Lady Downes' Seedling, forming one shoulder to the bunch, but is more massive, has larger berries, and the skin is not quite so tough. The berries are of the same shape as Lady Downes, and their flavour is superior to the Black Alicante. It seems to be an excellent keeper, some of the bunches having hung on the Vines for more than three months without shrivelling or deteriorating in flavour; moreover, the bunch does not scald as does Lady Downes. The variety Lady Hutt I have not grown, and cannot therefore speak of its qualities. Chas. Roberts, Halston, Shropshire.

GROS MAROC GRAPE, ETC.—I am, as a Scottish grower, very much interested in the discussion going on in the columns of the *Gardeners' Chronicle* in regard to the merits or demerits of Gros Maroc Grapes, and I am surprised that this discussion has been so long deferred, especially in face of the decision of the judges at the last September show held in Edinburgh, in placing Gros Maroc before Muscat Hamburgh and Madresfield Court in the class "for any other black Grape," more especially as the latter varieties were shown in splendid condition. I remember distinctly remarking to my friend, Mr. Boyd, who exhibited Muscat Hamburgh how fine they were, and I thought the bunches of Madresfield Court in the same class were perhaps the best of their kind in the show. That was not the only surprise; there were others in store—real "eye-openers," in the class for "six bunches in at least three varieties," and in the class for "four bunches, distinct." In the six-bunch class the judges awarded the 2nd prize to a stand containing four bunches of Alwrick Seedling, one bunch B. Alicante, and one Gros Maroc, against other stands having Black Hamburgh, Madresfield Court, Muscat Hamburgh, and Muscat of Alexandria. The same thing occurred in the four-bunch class; in fact, it would seem that quality was not recognised, as the coarsest and ugliest-shaped bunches of the coarsest varieties were those which had the preference. What do northern gardeners think of that? I noticed at the same show that the judges preferred the flavour of Black Hamburgh Grapes to that of Muscat Hamburgh. Mr. Temple (p. 728 of the last volume) goes on to lament the absence of these fine Grapes, Black Hamburgh, &c., from our exhibition tables of fruit at northern shows, and to say what grand Grapes were exhibited twenty and thirty years ago by the late Mr. Johnston, Meredith, &c. We are all of us perfectly well aware that quality was not neglected in Grapes in their day, but that fact is not disputed. Who is to blame for driving out the grand Grapes from our exhibitions if judges persist in ignoring good Black Hamburgh and Muscates in preference to such uneatable stuff as Alwrick Seedling, Gros Maroc, and Gros Colman, varieties which have nothing to commend them but their appearance. So long as these varieties are preferred and publicly recognised as superior to Black Hamburgh and Muscates, I am afraid the latter will continue to be conspicuous by their absence. David Andrie, The Gardens, Lubert House, Stirlingshire.

Obituary.

ALEXANDER CURLE.—It is with much regret we have to announce the death of Mr. Alexander Curle, which took place very suddenly on January 5, at his residence at Priorwood, just overlooking the ruins of Melrose Abbey. Over 300 mourners formed the funeral procession. Mr. Curle took a keen interest in all matters pertaining to art, archaeology, agriculture and botany, and he had an observant eye for all things beautiful in Nature, but it is more in our province to refer to him as a horticulturist. All his life long he loved his garden.

About eighteen years ago he commenced the culture of Orchids with a good general collection. Cattleyas were his favourites, and he was fortunate in securing

some very fine varieties, his motto being that a good plant required no more space and attention than an indifferent one. *Cypripedium* and *Masdevallias* were his next specialties, and of these he has left a very fine collection. He was successful in crossing *M. macrura* with *M. tovarensis*, which has produced a lovely hybrid, named in his honour *Masdevallia Curlei*.

Unlike many specialists, he had a capital knowledge of all classes of horticulture, and his whole garden and grounds were an interesting study. He also paid special attention to the culture of fruit-trees, and was well versed in their adaptability for various sorts of soil and temperatures.

TRADE NOTICE.

We understand that Mr. W. BURTON, well known in the gardening world, has re-entered the nursery business, and is now engaged with Mr. John Russell, of Hampstead, Brentwood, Richmond, &c.

— PARASITS. A better demand has prevailed the last few days. Prices range from 10s. to 100s. per bn., according to variety and quality. Large stocks still on hand.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns: TEMPERATURE, RAINFALL, BRIGHT SUN., ACCUMULATED, and a grid of daily weather data (Day, Deg., Day, Deg., Day, Deg., Day, Deg., 10th, 10th, Ins.) for January 20-29, 1897.

The districts indicated by number in the first column are the following: 0, Scotland N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties, 5, England, including London, 6, Principal Grazing, & Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; *Channel Islands.

ENQUIRIES.

"He that questioneth much shall learn much."—Bacon. CHRYSANTHEMUM SPORTS.—Mr. Henslow, Drayton House, Ealing, London, will be greatly obliged to cultivators of the Chrysanthemum if they will kindly inform him of any sports which they have had during the last two or three seasons, and to state the name of the parent plant as well as the colours of the flowers of both parent and sport; also to describe any special treatment the parents may have had. If they can suggest any other cause of the sport, he will be glad to know of it.

"R. D.R." asks: Is it usual for Magnolia grandiflora to set seeds in this climate out-of-doors? I have, he says, a large tree against my house (south aspect) which has now a fine seed-pod the size of a pullet's egg, conical in form, and with reflex spines. There is only one such pod, and it is the first that has appeared, though the tree has been there for thirty-six years. Is the seed likely to germinate? I have also had seed-pods of the common white Jasmine last summer for the second time in thirty years, but on north aspect. For figure of this plant see Gardeners' Chronicle, January 18, 1896, p. 80.

A correspondent, "E. P.," would be greatly obliged if some of our correspondents would tell him whether Citrinaria plants have leaves which curl up. He has them in a greenhouse with a night temperature of 45° to 50°; and higher by day, with sun-heat and ventilation.

NOTICES TO CORRESPONDENTS.

ADDRESSES: Will White Rose kindly furnish his full name and address, not necessarily for publication, but as a guarantee of his good faith. A WHITE FLOWERED CLIVEIA MINUTA: A. D. White-flowered forms of the species are not common. BEE: N. H. We should suppose that, in selling you Brazilian Bees for ordinary Red Bees, a mistake was made by the shopman, and that the firm of seed-dealers would make you some compensation. Of course, it would be necessary for you to prove that the produce was Brazilian Bees.

BOOKS: F. B. G. The Orchid Album, The Lindenia, Brussels; Copman's Dictionnaire, Iconographique des Orchidées. For culture, Williams' Orchid Growers' Manual.—R. H. Newton's Lawncare Gardener was published by Harbottle & Bogue, of Piccadilly. You might meet with this book and Kemp's How to Lay Out a Garden, at the second-hand book-shops, at very reasonable prices.

DIAGRAMS FOR CLASS-WORK: F. Regan. We think you would obtain these from or through Messrs. Williams & Norgate, booksellers, Henrietta Street, Covent Garden, W.C.

ESCAROLE: J. O'B. This is a mis-spelling of the Italian word Escarolo, or Endivia Escarolo, the Broad-leaved or Batavian Endive.

FUNGUS-PROOF SEED BOXES: R. F. G. Of "soft" woods the best would probably be Menel or red deal, and of hardwoods Oak, Eucalyptus, Teak. As an aid to preservation the wood might be primed with red-lead paint, and then receive two coats of paint of any desired colour.

GALVANISED WIRES: H. H. R. What the kind of action is that galvanised iron wire exerts on vegetation when in contact with it is not quite understood, but that it is injurious has been many times demonstrated. If the wire be coated with lead paint once or twice, no injury, except that which would be the result of severe pressure, is prevented. Plain iron wire, if coated with boiled linseed-oil, preserves it from rust for a time.

JERUSALEM CHERRY: C. X. We believe the name is sometimes applied to Solanum pseudocarpum, but it is not very appropriate, seeing that the plant has nothing to do either with Cherries or with Jerusalem!

NAMES OF FRUITS: E. H. P. 1, Golden Pearmain; 2, Mère du Montage.—C. Chaply, Mabbot's Pearmain.—J. Harris. Fruit much bruised—not recognised.—H. J. A., Fotherham. Round Winter Nonsuch.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—R. S. Bletia hincantia.—C. S. & Co., Limited. Chick Pea, Cicor arithum; Casa Banca is probably not a Pea at all, but a bulblet of Ornithogalum.—Newchurch. Lælia anceps Sanderiana.—S. S. Lycaste macrorrhizon, illustrated Bot. Mag., t. 4228, as Maxillaria macrorrhizon.—Noxie. The spiny crest of your very handsome spotted Odontoglossum seems to indicate some traces of hybrid origin, but it approaches O. crispum much nearer than O. Wilckeanum usually does. The white one is O. crispum, and the other O. luteo-purpureum, which two crossed would give O. Wilckeanum.—H. A. The varieties of Cattleya Trianaei seem to be very indifferent. They may be better another year, but never good. E. James. 1, Panax fruticoso; 2, P. laciniata.—E. S. Jersey. Probably Anagallis tenella, but we cannot be sure without flowers.—R. C. H. It appears to be Lælia anceps Williamsii.

ORCHARD LAND IN DEVON: Devonian. We should not advise you to plant Apple trees on the crab, or Pears on the wilding Pear on the shallow black loam overlying blue clay, as such trees would at the best be short lived, and the first-tanned would very probably get badly cankered when the roots of all kinds, Ficus as bushes or standards, and Pears and Apples on dwarfing stocks. Good drainage in any would be necessary over the whole area, including the land that was once an orchard, and was drained forty years ago. The drains should go below, or into the clay. The 3-acre field of red loam seems to be even less likely to carry fruit-trees for any great length of time. It would be well before deciding to rent this piece to inspect some orchards planted on a similar formation in the neighbourhood. In any case, it would grow bush fruit, Strawberries, and Ficus, and Apples, and Pears, on dwarfing stocks, and no drainage would be necessary, the gravel being immediately under the surface-soil. The northern aspect of much of the land would be an advantage in delaying the opening of the flowers of the fruit-trees.

PANCRATIDUM AND AMARYLLIS: C. R. H. We cannot find space in this column for full instructions. You should consult back volumes of the Gardeners' Chronicle, in which, within recent years, numerous articles on both subjects, especially the latter, have appeared.

POPLARS: N. C. In answer to your question, we give you the very latest information, taken from Britton's and Brown's Illustrated Flora of the Northern United States, &c., the first volume of which reached us on the same day as your question. The following table gives the American species. The Carolina Poplar is the last on the list, and is most generally known as P. monilifera, which name you will find it most convenient to retain, but deltoides is, it appears, an earlier name:—

- Petioles terete or channelled, scarcely or not at all flattened laterally. (POPLARS.)
Leaves persistent, and distinctly white, tomentose beneath. ... 1. P. alba.
Leaves glabrous, or very nearly so when mature, crenulate.
Foliage densely tomentose when young; capsulæ slender-pedicelled ... 2. P. balsamifera var. canadensis; capsule very shortly pedicelled.
Leaves broadly ovate, rounded or cordate at the base ... 3. P. balsamifera.
Leaves lanceolate or ovate-lanceolate, mostly narrowed at the base.
Leaves acute, short-petioled ... 3. P. angustifolia.
Leaves acuminate, long-petioled. ... 4. P. acuminata.
Foliage densely tomentose when young; capsulæ slender-pedicelled ... 5. P. therythylla.
Petioles strongly flattened laterally. (ASPENS.)
Leaves coarsely serrulate-dentate ... 6. P. grandidentata.
Leaves crenulate-dentulate.
Leaves ovate or suborbicular, short-petioled.
Leaves broadly deltoid, abruptly acuminate.
Leaves obtuse at the base; capsulæ rarely sessile.
Leaves truncate at the base; capsulæ slender-pedicelled ... 9. P. deltoides.

POTATO DISEASE: P. J. C. Many thanks for your reference. We do not think it has been proved that the bacteria of the wet-rot have anything to do with the Phytophthora. Assertion is not evidence.

TO KILL HYPOCHERIS RADICATA: E. M. Use rich mineral manures, such as sulphate of ammonia, superphosphate of lime, and the like; these, if applied for a few years, will cause the grasses to grow so densely as to smother out the weed.

VALLOTA PURPUREA: R. F. G. Pot the bulbs singly in 48's, or five in a large 32. If the bulbs are received when resting, do not let them remain out of the soil longer than can be helped, but pot them firmly in a mixture of two-thirds fibrous-loam, one-third leaf-mould, and sand in sufficient quantity to ensure the passage of water. Let the drainage be good, but do not let it occupy much space. As re-rotting should not be done frequently, it is advisable to mix charcoal in pieces of the size of a Hazel Nut in the soil, and put a layer of it over the cracks. The Vallota in a greenhouse bulb, whose leaves are evergreen, unless the bulbs are too severely dried off in the resting period, i.e., the winter season. In this respect it resembles the evergreen varieties of Hippeastrum, and like them it is well to rest it in a bed of spent tan, which prevents all overlying-off. In the spring, when growth commences naturally, bulbs which have been less than three years in their pots should have their drainage examined, and put right if found to be defective; have the soil knocked off the upper part of the bulbs, and be re-potted with some fresh soil on the top in the same sized pot—clean ones, not the pots out of which they came. After affording the plants water to moisten the ball throughout, stand them on a shelf in the warmer part of the greenhouse, or in a cold pit from which frost is excluded. Ordinary attention suffices in the summer, indeed, the plant does best—after the middle of June—in the open air. A very nice effect is produced by planting a dozen bulbs of flowering size in a deep pan, 12 to 14 inches in diameter. There are several varieties, all more or less pretty.

WORKS: L. Schmitt. You might apply clear lime water to the land, and afterwards gather up the many worms that this will drive to the surface. Encourage the birds, and keep ducks in the garden; trench the ground in the autumn state. Try liming, for it may be clogged with half-decayed vegetable matter, which favours the increase of worms.

THE

Gardeners' Chronicle.

SATURDAY, FEBRUARY 6, 1897.

THE SURVIVAL OF THE UNLIKE.*

(Continued from p. 70)

AFTER a consideration of Weismann's theories, Professor Bailey discusses the causes of variation under cultivation. There is primarily an excess of food-supply. "In short, the whole philosophy of the amelioration of plants rests upon excess of food-supply." "Secondly, it is a change of climate, and just as in nature special climatal conditions give rise to a peculiar facies to the plants within them, so "the same process of adaptation begins with domesticated plants the moment man takes them to climates of different kinds."

These remarks lead the author to make some very pertinent observations upon testing; for if a plant be wanted in different districts with unlike soils and climates, the "best tested" may utterly fail in certain regions though it flourish well enough elsewhere—as Mr. Bailey found with Strawberries only 3 miles distant! The fact is, that "each cultivator must test for himself, as he is the only person capable of knowing what varieties are best suited to the conditions of his land."

Two essays are devoted to insects and fungi, and the author points out that the great increase of these among cultivated plants is due to their finding such an abundance of host-material in cultivated areas compared to their restricted supply in nature, so that while man increases his crops, he unavoidably multiplies his enemies.

With regard to weeds, he points out the great importance of a rotation of crops as the best antidote; that the great spread of such a weed as *Salsola Kali* is due to a neglect of this fundamental principle of agriculture. The areas infested with this noxious weed is subjected to a continual cropping of Wheat, which allows the *Salsola* to grow; whereas it would be quite driven away by grasses.

In an essay on recent progress in American horticulture, the author gives very interesting details and statistics on the cultivation of Apples and Plums. These bring out the result that since they were first introduced from Europe the percentage of American forms has steadily risen, while that of the foreigners has declined. This proves how new and improved races have arisen, better adapted to the American soils and climates, affording more valuable fruit, so that the originally imported kinds cease to be cultivated. Besides this foreign source, large numbers of native wild plants are now cultivated, e.g., there are 200 varieties of native Plums. New species of Grapes are now coming into cultivation. "No less than 185 species of native plants for fruit or ornament were introduced into commerce last year."

The author begins the eleventh essay on the

national history of synonyms with the questions, "Is it possible for the same variety to originate twice? or is every new seedling a distinct variety? . . . Synonyms arise in three ways—by the bringing together of like plants of distinct origin, by the divergence or modifications of plants of like origin, and by the simple practice of re-naming. . . . The first two classes . . . are not only unavoidable, but they may serve distinctly useful purposes. . . . As a rule, the more synonyms a plant has, the greater are the assurances that it will thrive over a wide range of country, and in many diverse conditions; and in like manner, varieties which belong to well-marked tribes or families usually have the strongest or most virile characters." Mr. Bailey gives an amusing result of his attempt to simplify the nomenclature of Tomatos by reducing (by 50 per cent.) the numerous varieties to a few well-marked types. "But when I asked an experienced gardener for his opinion of the reduction, he remarked: 'Excellent! you have put similar kinds together, and I have ordered all the kinds which you refer to the Paragon! . . . So my effort, instead of lessening the number of varieties simply emphasized the value or characters of those which I had regarded as synonyms!'"

Hence issues a valuable result: that if a grower finds one of a type to succeed well with him, the probability is that other sub-varieties of the same type will also do so, as they will possess more or less the same constitution.

Essay No. 14 is on "Variation after Birth." As this has already been treated of in the *Gardeners' Chronicle*,* it need only be observed, that while Darwin's theory supposes that individuals are different when germinating, so that natural selection weeds out the unfit, "most plants start equal, but eventually come unequal." Indeed, it is obvious that the characters by which species are known are often not developed at all until the seedling has grown to maturity, as they may depend upon the flowers and fruits; i.e., long after the period when natural selection is supposed to act.

Essay No. 15 is headed "A Pomological Alliance," and is "a sketch of the relationship between American and Eastern Asiatic fruits." The author discusses the well-known fact that the flora of the Eastern States of North America is more nearly akin to the Japanese than that of the Pacific side. This is seen in allied species of plants and trees growing naturally in the two countries. Horticulture corroborates this, in that the Japanese Plum does better than the European. He concludes with a list of twenty-two Europe-Asian fruits, and twenty-one of Eastern Asian origin now cultivated in the United States.

In the sixteenth essay on horticultural geography, the author returns to the important question of studying the adaptability of varieties to geographical and local conditions. Of course, those are more pronouncedly different in a large country like North America than in England, yet we have quite sufficient variation of soil and climate in the British Isles to make this a more important matter for the consideration of horticulturists here, than perhaps at the present time obtains. Much disappointment may arise by the "promiscuous distributing of varieties over great areas. . . . I believe that the days of the nursery business, which aims to feed the whole country, are numbered. Separate nurseries for widely different localities will be necessary, and climate and environment must force the nurseries into

nearly as narrow limits as the adaptability of the stock which they grow." This suggests the idea of testing plants at Chiswick in very different artificially-made borders, by mixing clay, lime and sand, in unequal proportions, each of the three ingredients largely preponderating over the other two in the three borders, respectively.

Essay No. 20 discusses the old question—Do cultivated races die out? From a circular sent out on Apple-trees, the general reply was, that they are shorter-lived now than formerly; but when one investigates the supposed causes, they are reduced to eight, viz., a change of climate, a greater abundance of insects, also of fungi, high cultivation, a lack of adaptation, neglect, and bad methods of propagation and of pruning. Mr. Bailey refutes most of these, and concludes by saying:—"The chief particular causes appear to be lack of adaptability of varieties to regions and conditions, climates unfitted to the best development of the species, and lack of fertility of soil."

Part III. commences with the twenty-fifth essay, "Whence came the cultivated Strawberry?" The next two are called "The Battle of the Plums," and "The Evolution of American Grapes," and are of more interest to Americans than Europeans; while the twenty-eighth is devoted to the Carnation, and the twenty-ninth to the Petunia. The hybrid origin of existing forms of this last is well known; though he is not aware of a fact which was told the present writer by one of our most eminent florists, that the double form was unknown until it appeared suddenly both on the Continent and in England in the same season.

The last and thirtieth essay is devoted to the amelioration of the garden Tomato. This has proved to be a most variable plant. The study of all the forms of the larger sorts leads to the Cherry Tomato as the origin (*Lycopersicon cerasiforme*), and as five-sixths have red fruits, this was probably the original colour. Then follows an interesting history of the "Trophy," the result of twenty-four years crossing and careful selection. The Tomato, therefore, affords one of the best examples of wide differentiation into varieties from a single species, or the other true species (*L. pimpinelliforme*), or Current-Tomato, appears to have had nothing to do with it.

Taking the book as a whole, it is a valuable contribution to the literature of the evolution of plants, for it is by one trained, not only in practical horticulture, but to look at plant evolution under the hands of a gardener, from a philosophical point of view. Although the author still says he accepts natural selection, yet when he describes all he sees going on around him, he (as it seems to us) practically ignores it as a necessary means in the origin of varieties, races, and species. *George Henslow.*

ORCHID NOTES AND GLEANINGS.

BULBOPHYLLUM COMOSUM.

THIS curious species has been sent to us for identification by several of our correspondents. The species is found in Eastern Burma, and on the Shan Hills alt. 6000 feet, and to the recent importations from these hills its more frequent appearance lately is due. The stout ascending scapes are furnished at the top with drooping racemes of closely-set, small white flowers, each measuring about half an inch in length, and covered with short hair-like processes, the whole head having resemblance to a bottle-

bush. It belongs to the deciduous section, the members of which require to be dried off for a time after the leaves fade, and which include *B. lirtum* and *B. auricomum*. A peculiarity of this section of *Dalibophyllum* is that the entire plant, leaves (especially when drying-off or dried) and flowers, have a delicate but strong odour of new-mown hay.

ODONTOGLOSSUM HALLI LEUCOGLOSSUM.

Odontoglossum Halli, which is called by some persons the grandest of the Ecuadorian *Odontoglossums*, may primarily be divided into two distinct sections, viz., that with the ground colour of the labellum yellow, with brown blotches, and that with a white lip, more or less spotted with chestnut-brown, the latter being usually called *O. H. leucoglossum*. Both sections are liable to much variation, probably, to a great extent, in consequence of its rather wide range of distribution in the Andes of Ecuador, and hence what are known as good or bad varieties frequently appear in every importation of the plants. A fine example is at the present time flowering in the gardens of Joseph Broome, Esq., Sunny Hill, Llandudno, who has kindly sent a bloom of it. The sepals, which are more than 4 inches across, are of a bright yellow colour, covered with large, irregularly shaped, red-brown blotches; the broader petals are likewise of a bright yellow colour, and furnished with numerous, small, oblong-shaped red-brown blotches; and the recurved tips of each segment are yellow. The white lip is more than 1½ inch broad, fringed at the margin, and decorated with chestnut-coloured spots, and the middle area of the lip has several large blotches of the same colour. The conspicuous crest is of yellow and white, marked with red lines. It is a handsome variety, and resembles, in almost every respect, the flower of *O. Halli Lindenii*, illustrated in *Lindley's*, vol. iv., p. 83.

ORCHIDS AT NEW HALL HEY.

By the kindness of G. W. Law Schofield, Esq., New Hall Hey, I had recently the privilege of carefully inspecting his fine collection of Orchids. The houses are full of healthy plants, including many rare and very fine species. The first range, in three divisions, is span-roofed, with sunken paths; and in the first two divisions are some finely-grown *Celogyns*, *Laelia anceps*, *L. a. var. Hardyana*, *L. a. var. Schrodero*, *L. a. alba*, *L. a. Dawsoni*, *L. a. Sauderia*, &c., in flower; also, the beautiful and rare pure white *Pleione maculata alba*, and many other species. The third division is filled with *Cypripediums*, and amongst these are some choice crosses. In flower were such plants as *C. insigne Sanderae*, *C. Charles Rickman* ×, with three fine flower-spikes; *C. Leyceaniaum* ×, *C. Arthurianum* ×, *C. vexillarium superbum* ×, *C. Ceres* ×, *C. Calypso* ×, *C. Lathamianum giganteum* ×, *C. Leeanum* in great variety, including the best forms of *C. Leeanum superbum* ×, *C. L. Mascarellianum* ×, and *C. L. giganteum* ×.

In this division seedling *Cypripediums* are germinating, and growing luxuriantly. The second range of houses is also span-roofed, and in two divisions, one of which is devoted to the culture of *Dendrobiums*, but has become so over-crowded, that Mr. Schofield has had to devote an extra house to these plants. We noticed *Dendrobium illustre* ×, *D. Venus* ×, *D. Schroderiaum* ×, *D. Aspasia* ×, *D. Cylele* ×, *D. melanodiscus* ×, *D. Juno*, *D. Rainbow*, *D. Luna*, *D. The Pearl*, in dozens or half-dozens. There are also some fine specimens of *D. nobile nobiliss*, *D. nobile giganteum*, *D. nobile Ames*, *D. nobile Cooksoni*, *D. Wardiaum album*, &c. The other division is devoted to *Cattleyas* and *Laelias*, including many fine hybrids.

The whole of this collection is well grown, and great credit is due to Mr. Schofield's head-gardener, Mr. E. Shill. A. J. K.

CALAMUS CILIARIS.

THERE are in cultivation species belonging to this genus which possess much beauty; but perhaps the most beautiful and useful of them all, from a decorative point of view, is the subject of this note,

which is a plant that should be grown in every stove. It would make an excellent plant for the dinner-table, or for exhibition. It is of slender growth, the stem measuring in diameter from a quarter to half an inch; the leaves are about 1 foot in length, and 6 inches in width at the widest portion, with their margins beautifully ciliated; the petioles are about 2 inches long, bearing a few small hooked spines, and sheathing at their base. When about 18 inches in height, it throws out from near the top of the sheath a very slender growth, as shown to the left of our illustration, which is covered with numerous small hooked spines to aid the plant in climbing. The accompanying woodcut (fig. 23) illustrates these

better be cut off, as they are liable to hang on to anything with which they come into contact. The plant is a native of India, and was introduced in 1869. *W. Harrow, Sheffield.*

AMERICAN NOTES.

[From our Special Correspondent.]

DEATH OF WILLIAM ELLIOTT.

WILLIAM ELLIOTT of Dey Street, New York, U.S.A., senior member of the firm of Wm. Elliott & Sons, died at his home on January 16. To those of the

FIG. 23.—CALAMUS CILIARIS.

climbers, also two flowering-spikes to the right upon the plant. The plant represented was from 5 to 6 feet in height, and grows in one of the plant-stoves in these gardens.

It is easily propagated from offsets which are produced somewhat freely from about the base of the plant. They should be detached when 4 or 5 inches in length, as when about that size they are almost certain to have a few roots upon them. These little offsets should be potted into small pots in a mixture of equal parts of loam, leaf soil, and sand, and be put into a close case in a warm-house; no bottom-heat being necessary in the case where, if rationally treated, they soon push their roots into the soil. When used for dinner table decoration, the climbing tails had

English trade who had dealings with us, the name of William Elliott had been familiar for years, and with him passes away the last of the old school of New York seedsmen; as an auctioneer perhaps he will be best remembered by some, having been engaged in that line of business since 1858, when he entered into partnership with I. J. Young. William Elliott was born at Crulling, Jedburgh, Scotland, on October 10, 1824; his father and grandfather having been gardeners, he was brought up to the same profession, being apprenticed at the Earl of Minto's gardens, near his birthplace. He was subsequently in the gardens of Sir E. Trevelyan at Wallington Hall, and later at Ripley Castle, Yorkshire. Coming to London he entered the well-known nurseries of J. & C. Lee at

Hammersmith, and the writer has often and again heard him repeat his experience there, and how he went to the Chiswick Gardens for his firm. After an unsuccessful attempt as a wholesale fruit salesman in Edinburgh, Elliott turned again to gardening at Sawley Hall, Ripon, Yorkshire, and later went to Liverpool to the Skirvings' Nurseries. On the persuasion of his friend, Kerr, he sailed for the United States in 1851, and was variously gardener, florist, and market gardener near New York. In this last essay he lost what money he had, and turned to

A SCARCITY OF ORCHIDS.

In the very nature of things, when one considers the facts that Orchids are of such slow growth, and that they have been gathered by the ship-load to satisfy the cravings of the orchidophiles of the temperate climes, I say, in the very nature of things, the end must come. The forests which contain the gems are not unlimited, and unless new, untried districts be opened up, a halt must be called to this greed of collecting. A letter lately received from the collector, J. E. Lager, who is at present in the U. S.

a direct charge against the tactics of some European firms, whom he charges with "over-zeal" in this wise:—

"Men are sent out with instructions to remain in one place three or four years, or even more, the consequence of which is that the owners of the forests staidly, and very naturally, think there are millions to be made in the business, and prohibit the extraction of the plants unless the collector is willing to pay tribute." All this in reference to *Odontoglossum crispum*.

Cattleya chocoensis is still plentiful, but becoming rare as the forests are cleared for pasture; *Cattleya Mendeli* is fast disappearing. *Cattleya Schroderae* is comparatively abundant, but its extraction is expensive. The letter which appears in full in *American Gardening*, for January 23, closes with the following pertinent remark: "The day is not far off when these beautiful plants will be extinct." I have quoted freely from the communication referred to, as it seems to contain matter worthy of serious attention by plant-lovers everywhere, and it would be well that prominence be given to the caution. It is not often that we are able to place before the public the actual thoughts of these intrepid men, who carry their lives in their hands while they are hunting out treasures for our greenhouses and stoves.

THE TARIFF QUESTION.

Politics cannot be kept out of horticulture in the United States of America, and on certain questions of "tariff" there are many disunited conditions. President elect, Wm. McKinley, is well known as a protectionist, so all the trades well loaded up with imported stock are seeking to be able to place goods on the market next sea on with the guarantee of protection from the foreigner. Whether this be dealing in Palms, Azaleas, fruit-tree stocks, Roses, or what not, a high tariff is being agitated for by nearly all sections, and the prospects are that a high tariff will rule.

MYRIOCARPA LONGIPES.

The accompanying illustration (fig. 21) represents a very remarkable and peculiar plant which flowered in the Victoria regia house of the Sheffield Botanical and Horticultural Society's garden during the summer of last year. The flowers are small, and are arranged upon the long racemes which extend to the bottom of the pot as seen in the illustration. These ribbon-like racemes were nearly 5 feet in length; when young, they are of a whitish or cream colour, changing to a shade of green as they become old, hundreds of minute flowers being arranged on the racemes. The foliage is large and ornamental, the blade of the leaf measuring from 18 to 20 inches in length, and from 9 to 12 inches in width at the widest part; and the margin of the leaf is serrated. Their colour is a light green, with parts of a dull, silvery hue. The petioles are about 6 inches long. Cuttings of the plant strike without much difficulty in a warm propagating-case, if a slight amount of bottom-heat be afforded; and plants can be grown in one year to the size of that shown in the illustration from cuttings. The plant belongs to the natural order Urticaceae, and is a native of North and South Tropical America. *William Herron, Sheffield.*

CRATEGUS.

It is common with most hardy trees and shrubs, the *Thorn* fruited last year with wonderful freedom. It is some years since their autumnal beauty has been so great. The respective merits of the different species have, in consequence, been clearly shown, and the present time seems suitable for discussing the genus; more especially as there appears to be a good deal of confusion in gardens as to the identity of many of the species. London, fifty to sixty years ago, reviewed the genus fully, and his work has retained much of its value, a large proportion of the species being then well known under names they still retain. Lindley, too, paid special attention to the

FIG. 21.—MYRIOCARPA LONGIPES: WITH PENDULOUS RACEMES OF SMALL GREENISH FLOWERS.

Canada as a farmer, but quickly changed his mind; and after being about New York for a time, entered the seed business in 1851. The firm of Young & Elliott, seedsmen and horticultural auctioneers, was well known in England till 1889, when, owing to the death of the senior partner, Elliott took into the concern his two sons, by whom the business will be carried on. The career of William Elliott has been full of incident, and nothing pleased the old gentleman more than to recount to those who were from "over the water" something of what he had seen in an eventful life. A Scot to the backbone, he was a trusty friend, a severe and caustic critic, but without ever ready with a kindly word.

of Columbia, strikes the alarm-bell. "Five years ago," he writes, "I myself thought that the regions where *Cattleya Triand* occurs, and also that of *C. gigas*, were inexhaustible. . . . Now, in the very best districts, the plants are very much retired, causing heavy expenditure to extract them. Freight has increased 100 per cent." This last item is accounted for by the scarcity of beasts, who do the hauling, because they are used up in the largely-growing Coffee industry; moreover, this Coffee industry is extending at the expense of the Orchid forests, "for it happens that the Coffee region is exactly the Orchid region."

Mr. Lager, whose *bona fide* none will doubt, makes

Thorus, and figured many of them in the *Botanical Register*—a work that is well worth consulting in connection with the genus. At quite a recent date the American species have been described by Professor Sargent, and admirably figured in the *Silva of North America*. But no easily-accessible descriptive account of the whole genus has been published in the English language for a long time. It seems, therefore, worth while to bring together a few notes on all the species worth growing; and there are very few of which so much cannot be said. The names here used are those adopted at Kew, the collection there being probably the most complete in species and varieties, as well as the most correctly named in existence.

Cratægus is a genus confined to the northern half of the globe, and is in number of types most abundantly represented in North America. Another well-defined group (of which *C. Azarolus* may be taken as the type), comes from the Orient. The remainder are scattered over Europe and North Asia, and two or three species reach North Africa. The most widely-spread of all the *Thorus* is *C. Oxycantha* the Common Hawthorn, which occurs wild in all the three continents of the Old World. In botanical relationship they come nearest to the *Mesplis* (—indeed, the tree known as *Mesplis grandiflora* or *M. Smithii* is surmised to be a natural hybrid between the two genera. They are all trees of bushy or rounded habit, varying from a few feet to 50 feet in height; for the most part, however, ranging between 10 and 20 feet. The flowers are white, or nearly so, and are generally fragrant, although the fragrance is not invariably agreeable. It is not necessary to say much in regard to their cultivation. They all like a free open soil of good depth, which should be of at least moderate richness. All of them, no doubt, are more healthy and longer lived when raised from seeds; but owing to the length of time seedlings require to reach the flowering age, they are very frequently budded standard high on the common Hawthorn. This method of propagation does not appear in the case of the *Thorus*, to have the marked disadvantages that can so frequently be noted in connection with hardy trees and shrubs that have been grafted or budded. The numerous varieties of *C. Oxycantha* are almost necessarily increased in this way. The comparatively small size of the *Thorus*, as trees, renders them especially well adapted for gardens of limited extent; and their two seasons of beauty—in flower and in fruit—give them a special claim to the notice of planters.

The following is a list of the species here dealt with:—

OLD WORLD.

- C. Azarolus* (syn. *C. Aronia*).
- C. heterophylla*.
- C. melanocarpa* (syn. *C. Oliveriana*).
- C. nigra* (syn. *C. Lambertiana*).
- C. orientalis* (syn. *C. odoratissima*, *C. sanguinea*).
- C. Oxycantha* (combining *C. monogyna* and *C. oxycanthoides*).
- C. pinnatifida*.
- C. p. major* (syns. *C. californica*, *C. Layi*, *C. Korolkovi*, *C. chinensis*, *C. tartarica*).
- C. Pyracantha*.
- C. sanguinea*.
- C. sinica* (syn. *C. macrocarpa*).
- C. tanaecifolia*.

NEW WORLD.

- C. Carrierei* (syn. *C. Lavallei*), probably a hybrid.
- C. coccinea* (syn. *C. rotundifolia*).
- C. c. macrocarpa* (syn. *C. macrocarpa*).
- C. cordata*.
- C. Crus galli*.
- C. Douglasii*.
- C. flava*.
- C. mollis* (syn. *C. coccinea* var. *mollis*).
- C. punctata* (syn. *C. tomentososa* var. *punctata*).
- C. spatulata* (syn. *C. microcarpa*).
- C. tomentososa*.
- C. undiflora* (syn. *C. pinnatifida*).
- C. viridis* (syn. *C. arborescens*).

THE OLD WORLD SPECIES.

C. Azarolus.—A species of great beauty, of much the same character as, and nearly allied to, *C. tanaecifolia* and *C. orientalis*, and like them, a native of the Orient. The leaves are very deeply cut into five or seven somewhat rectangular lobes, and are of a greyish-green colour, the mature leaves being nearly or quite glabrous above, but pubescent beneath. The flowers are white and showy, appearing in May and June. The fruits are $\frac{3}{4}$ to 1 inch across, globose, and vary in colour from orange yellow to scarlet. This is a small tree 10 to 15 feet high, and is a most desirable species. The *Cratægus* figured by Lindley in the *Botanical Register*, t. 1897, as *C. Aronia* is now considered to be a yellow-fruited form of *C. Azarolus*. The species is cultivated in southern Europe for its edible fruits, which show great variation in size and colour.

C. heterophylla.—An interesting Thorn, and distinct, on account of its variously shaped leaves, some of which are narrow-oblong, rounded or pointed at the apex, and almost or quite entire. Others are larger, rhomboid in general outline, but cut into deep, pointed teeth. The small, entire leaves are characteristic of the fruiting branches; the larger, deeply-toothed ones appear on strong sucker-shoots, and have at the base a pair of large, curving, toothed stipules; there are, however, plenty of leaves intermediate between these two kinds. The fruit is ripe towards the end of September, and is of a bright rich red, oval, and about $\frac{1}{2}$ inch long, the calyx-lobes being triangular and pointed. The species is a native probably of south eastern Europe or the Orient. It has been suggested that it is a hybrid between the one-seeded variety of the common Hawthorn (*monogyna*), and one of the *Azarolus* group. It is a small tree of somewhat erect growth, and produces its abundant white flowers in May.

C. melanocarpa (*C. Oliveriana*).—Both by Loudon and Lindley this *Thorus* was considered to be a variety of *C. Oxycantha*; the latter figured it in the *Botanical Register*, t. 1833, as *C. Oxycantha* var. *Oliveriana*. The leaf is of much the same shape as that of the common Hawthorn, but is downy on both sides, especially beneath, and of a greyish colour. The young wood also is downy. The fruits are very plentiful, and about the size of common haws, but are black, and covered with short hairs; they are ripe in September. This is a distinct-looking small tree, a native of the Caucasus.

C. nigra.—A hard-woody species, which is a native of Hungary. Its wood is covered with a dark grey tomentum; and the spines, which are not very abundant, are stout and straight, and under half-an-inch in length. The leaves are very downy beneath, especially on the veins and midrib, and have a well defined petiole; the blade is 2 to 4 inches long, broadly ovate, lobed, and coarsely toothed. At the base of the petiole there are two somewhat sickle-shaped, deeply-toothed stipules. The flowers appear at the beginning of May, and are white, but turn a purplish shade with age. The fruit ripens early, and is black, and about the size and shape of a Black Currant. *C. nigra* is a round-headed tree, 15 to 20 feet high, and was introduced in 1819.

C. orientalis.—A species having much the same appearance as *C. tanaecifolia*, but easily distinguished from it by the absence of mossy bracts at the base of the fruit. The leaves are $\frac{1}{2}$ to 2 inches long, very downy (as is also the young wood), and lobed almost to the midrib, each lobe having several coarse teeth at the top. The stipules are large, curved, and deeply toothed. The white flowers are borne towards the end of May. The fruits, which become ripe in September, are slightly flattened like an orange, and measure about three-quarters of an inch in thickness; they are covered with pubescence, and the colour is either bright yellowish-red or dark dull red, according to the variety. Lindley figured the dark red-fruited one as *C. orientalis* (*Botanical Register*, t. 1852), but it is better distinguished as var. *sanguinea*. Subsequently, and in the same publication (t. 1855), he figured the yellow fruited variety as *C. odoratissima*, which may now stand as the varietal

name. The branches sometimes terminate in a spine, otherwise they are nearly unarmed. The species was introduced from the Levant in 1810, and is a small spreading tree 15 to 20 feet high. *W. J. Bean*.
(To be continued.)

PLANT PORTRAITS.

BEGONIA MARTIANA, *Garden*, Dec. 12.
CATELEYA × MASSILIENSIS. A cross by M. Maron between *Cateleya Trianae* (probably) and *C. Dowiana aurea*. Sepals narrow, spreading; anterior lobe and lip undulate with a crimson blotch; throat, yellow line. *Beve Hortode*, January 1.

COLONIAL NOTES.

THE NEGLECT OF NATIVE PLANTS BY COLONISTS.

YOUR editorial headed "Colonial Horticulture" in the *Gardeners' Chronicle* of November 28, 1896, deserves the fullest sympathy from all of us who are connected with the horticulture and botany of the British West Indies. Our several botanical gardens could do much in cultivating and furthering the improvement of our wild plants of horticultural merit; and much creditable work in this direction is doubtless often done. It seems the same with us in this part of the world as it is, or was, in Amstedda. Intense enthusiasm is shown by colonists, even by those who have never visited Europe or America, over *Chrysanthemums* and the like; but little notice is taken of indigenous floral beauties growing at our very door. This retards in a great measure the cultivation and improvement of the beautiful forms of vegetation. These remarks I make are founded on personal experience and observation.

EUPATORIUM GIGANTUM, L.

At the present moment, the hedges and open places round about Grenada are one mass of flowers and bursting buds of this plant. Their lilac-coloured flowers are the predominating feature among the flowering plants here at the time of writing, especially on the low levels near the sea. In shady positions the plants grow into a half-climber, climbing about among the nearest shrubs. It is, of course, an old favourite at home in hot-houses, for I saw it mentioned quite recently in the *Gardeners' Chronicle* as being one among a selection of plants at an exhibition; and I knew it well in the Old Country many years before I saw the plant growing in its native wilds. It is locally called the "Christmas Bush." *W. E. Broadwing, Grenada, B.W.I., January 7.*

VEGETABLES.

BUNYARD'S EARLIEST DWARF PEA.

This is a variety that I have grown for some years, and so far it has always proved very hardy, producing heavy crops of good-flavoured Peas. Its height is about $2\frac{1}{2}$ feet, and the pods contain usually from eight to ten seeds. For the earliest crop, I sow the seed on trenched ground, making the seed-drills firm at the bottom, believing that by so doing I get the plants to grow more sturdily, and withstand frosts well. For several years I have been a great advocate for using trenches in Pea culture, especially for the mid-season sowings, and placing at the bottom a thick layer of manure. Usually with this kind of treatment the crops are good; still, I have my doubts whether in a very dry season the crops are as good as would be the case if there were less manure used, and the soil made firmer. As a rule, I find the haulm is inclined to be too rank and sappy, with the result that the flowers do not set as well as when the stems are of moderate strength. Telephone makes a good second early, but I have not succeeded with it for later use, excepting for the very latest supply—when I have had it, indeed, very good. Last year, although a bad year for Peas, Goldfinder and No Plus Ultra did very well, but the best to withstand the drought were Champion of England and J. Maclean, both old, well-tried varieties. I intend to sow Peas on a much firmer, deeply-worked, rich soil. *H. Markham.*

CAULIFLOWER AND EARLY BROCCOLI.

It is not often that we are favoured with mild weather, as was the case this year up till January 16, for up to that date there had scarcely been sufficient frost to check the growth of either late Cauliflowers or early Broccolis, so that we were enabled to keep up a continuous supply to the kitchen from the open ground till real wintery weather set in. Last autumn, as most gardeners will well remember, was not the most favourable for establishing young plants of these, especially the period between June and the end of August. May was a very dry month, and growth was consequently slow, and though June was showery, there was not sufficient rain to thoroughly moisten the ground, particularly where it had been recently turned up and exposed to the weather. There is a vast difference in the working of soils, and gardeners have to make themselves acquainted with this if they would work in a profitable manner; and as the preparing of the ground for each crop adds much to the success or failure of the same,

the plants should never be allowed to touch each other even in the seed bed. One great failing is, that seed for various reasons does not cover sufficient ground, sometimes on account of want of space, at others through carelessness in sowing. To keep up a continuous supply, it is not so much the quantity sown at one time as the using of the proper varieties to succeed each other. There are now a number of varieties of autumn and winter Broccoli that will resist a certain degree of cold, on account of their close, compact hearts, and the leaves folding over close together. Snow's was formerly considered to be one of the best for use in the early winter, and is so still where the true stock is kept. The time of sowing the seed has also much to do with keeping up a succession, as it is almost useless to sow a late variety early with the hope of preventing a blank; but early varieties sown late and kept on growing, will prolong their season. There are, however, exceptions in this case, for if the seed of late Cauliflower be sown early, the plants will turn-in just at a

hold of the plants seriously, much trouble is experienced in keeping them through the winter. As a rule, however, if the early varieties are taken up in the autumn and put close together, so that they may be covered with mats and litter, which afford occasional supplies even in hard weather; and in mild weather they turn in much faster, so that if either cut and placed in a cellar, or pulled up and hung in a shed out of the way of frost, they are found to be good eating. *H. C. Prinsep.*

PHILADELPHUS LEMOINEI VAR. "AVALANCHE."

This is a beautiful gain of M. Lemoine of Nancy. It is a hardy shrub, attaining a height of 5 to 6 feet, with decurved branches, small leaves, and fragrant white flowers. The illustration (fig. 25), taken from a photograph, shows well the habit of the plant.

THE PEACH OUT-OF-DOORS.

The subject mentioned by your correspondent, Mr James Mayne, had my consideration some years ago, and caused me to adopt on a small scale invisible wire-netting of the widest mesh, and of fairly stout wire. Its advantages over the usual method of wiring are appreciable on reflection, that the Peach and Nectarine trees adapt themselves to this system, which allows all the fruiting-growths to be secured with precision as required, but to attain which, the usual style of wiring is less amenable. Morello Cherries would probably also answer, whereas for other wall-fruit, having only spurs to deal with, the separate wire-system has greater advantages.

The desire to see the trees so close as to be almost or actually in contact with the wall, does not seem to me well justified, as I fancy sufficient, if not even greater, heat in summer is to be found at several inches from the wall by assistance of the natural radiation. My idea is, that having temporarily tied the tree back, strong and rather long, hook-shaped staples should be driven into the wall at the extreme top of the space to be covered by the tree, the wire-netting fixed, after which the stretching downwards, and securing by similar staples at the base and sides is very simple. If suitable piers are provided in the wall having 3 to 4 inches extra thickness, they would lend themselves to fasten sides of netting to their face even yet more easily. The number and strength of the staples must, of course, be regulated by the height of the wall and the width of the space. After the insertion of a moderate number of these latter, their number should be added to after ro-yting the tree wherever its trend and bend disturbs the surface-level of the netting, or wherever the force of the wind may indicate weakness. The location of the tree at several inches from the wall will also mitigate against depredations by insects, and keep the whole generally cleaner than close wiring or nailing to a wall.

For the purpose of strengthening the fabric in the case of walls being high, a pair of thin rods fixed crosswise would be a great improvement, if tied to the netting here and there; or since of late years thin Bamboo canes have become very cheap, these could take the place of rods with even greater advantage. The number of staples would be much reduced thereby, one of which in the very centre holding the canes at their points of crossing would be very serviceable.

I should be quite satisfied to adopt the plan on a larger scale, as it has several advantages, and hardly requires the entire loosening of the trees, except at long intervals, the operation of washing the tree being done with relative facility on having the tree fixed at 3 to 4 inches from the wall.

Where piers exist, the monotony of a long Peach-wall would be greatly relieved by a series of girdron-trained Pear trees of the finest and latest varieties, to be grown on the piers, and even the latter may be absent entirely, and the same effect be produced by Pear and Peach trees alternating. *H. R. H. Forest Hill.*

FIG. 25.—PHILADELPHUS LEMOINEI VAR. "AVALANCHE."

this branch of gardening must not be neglected. To retain the moisture in the ground, it should be worked in the autumn or winter, so that it may become consolidated again before the dry weather sets in; but where so many crops have to be taken from the same plot, and in close succession, it is very difficult to treat all of them as one would wish. Where there is not this necessity for such heavy cropping, there ought not to be any trouble either in getting crops in at the proper time, or on suitable ground. Some gardeners plant Broccoli after early Peas or Potatoes, and so on; but it would well repay to reserve a plot for these that has not been previously cropped that year, if possible—or failing this, to plant them between the early Potatoes as soon as they were earthen up, allowing a greater distance between the rows for that purpose. As late Broccolis occupy the ground for a long time, it is essential, if fine heads of close texture are to be produced, that the ground be in good heart, and that sufficient space be allowed between the plants for the foliage to develop to its full size. There is much art, too, in keeping the plants steady, for the closer the foliage is to the ground the stouter the stem. To attain this end,

time when it is most difficult to produce fine heads from the other varieties. For example, in a dry season much better Cauliflowers are produced in August and the early part of September, from late varieties sown on a warm border in March, than from other varieties the seed of which is sown in April or May, for the simple reason that the plants have got established before the ground has become hot and dry. From August to the middle of last month, there was no gap in the supply, which began with Autumn Giant, followed by Autumn Mammoth, Michaelmas White, Veitch's Self-protecting, Christmas White, Vanguard, and Winter Mammoth. The last four are Broccolis, the seed of which was sown early in the month of March, and in April for succession. They were all lifted in the early part of November, and placed together with their heads towards the north, so that protection might have been afforded them if severe weather had set in. Since January 16 very cold rough weather with wind from the north and north-east has prevailed, putting a stop to the growth of the plants for the present, and obliging us to depend for supplies from protected plants. Broccoli is such a precious crop that in places where the frost takes

CULTURAL MEMORANDA.

COLEUS FOR EXHIBITION.

COLEUS is one of our finest foliage plants, and for the ornamentation of conservatories it is very effective when mixed with Palms, Ferns, and other green-leaved species. Some of the recent varieties are shaded and blotched with exquisite colours on grounds of cream, green, purple, and reddish shades. It is well to strike the cutting in the month of March or April, according to the amount of convenience at command, in a temperature of about 70° or higher, placing each cutting in a thumb-pot in soil consisting of one part loam, and one of leaf-mould, one of coarse silver-sand. Till rooted the cuttings should be kept close, and potted-off as soon as rooted, and shifted on till the plants reach the required size, keeping them always close to the glass. A plant in a 3-inch pot is large enough for general use, but for exhibition they may reach 16's, making fine specimens if nicely staked out, and the tip pinched occasionally to produce laterals. When the pots get filled with roots, liquid manure-water should be afforded about twice a week, and there is no better than Clay's, in which a small quantity of soot is squeezed through a bag. Always use tepid-water to the plants. The secret of success is to get pot-bound plants, and then, by using plenty of manure-water, and heat and light, to keep them in good condition. The house should be shaded with light shading in the hot days of summer, as the sun is apt to scorch the foliage if this be omitted. *A. W. Young, Stearns.*

AMERICAN PALMS.

THE PALMETTO.—It is remarkable that Sabal Palmetto, which might be expected to be the hardiest of all arborescent Palms, has remained so rare in gardens. A plant has long been cultivated in the Palm-house of the Royal Gardens at Kew, in England, and the species is said to be established in Ceylon. In California, where nearly all the Palms of temperate regions grow vigorously, it has not proved a success; and it appears to be unknown in the gardens of Southern France and the Riviera, although it is said to flourish in those of Southern Italy.

"On June 28, 1776, a force of less than one hundred Carolinians, under command of Moultrie, protected by the rude fortification on Sullivan's Island in Charleston Harbour, made of the trunks of the Palmetto, repulsed the attack of a British fleet under command of Sir Peter Parker; and when the State of South Carolina was organised, the State-ship, which was first used in May, 1777, was made to commemorate this victory. A Palm-tree growing erect on the sea-shore represents the strength of the fort, while at its base an Oak-tree torn from the ground and deprived of its branches recalls the British fleet built of Oak timber, overcome by the Palmetto."

Washingtonia.—First collected by Dr. Edward Palmer in 1857 in secluded clefts of the mountains about Guaymas, and subsequently at La Paz, Lower California. Washingtonia Sonora, which is still very imperfectly known, is described as a tree 25 feet in height, with a trunk a foot in diameter, and glaucous, filiferous leaves, 3 or 4 feet in diameter, borne on comparatively slender petioles, beset on the margins with variously curved spines, connected by a web of floccose hairs. The spadix is shorter, more slender, and more sparingly branched, and the perianth is thinner and more scarious than those of Washingtonia filamentosa. The seeds, which are flattened-globose, and about an eighth of an inch long, are used by the Indians of Lower California as food.

Another species, Washingtonia robusta, has been described (H. Wendland, *Berlin Gartenzeit.*, ii, 198 (1853); André, *Rev. Hort.*, 1855, 101, 1, 77; 1895, 155. Watson, *Proc. Am. Acad.*, xxv, 136; S. B. Parish, *Garden and Forest*, iii, 52, 542; Zov. iv, 350; Orenitt, *W. Am. Scientist*, i, 63, 70). Washingtonia robusta appeared about 1869, in Linden's nursery in Ghent, among a number of plants of Washingtonia filamentosa which were raised from

seed believed to have been obtained from Lower California, and may be a seasonal form of this species, as is now usually believed, or more probably, a species from lower California, still unknown in a wild state. In gardens, where it has not flowered, Washingtonia robusta is a more vigorous, and more rapid growing plant than Washingtonia filamentosa, and its darker green and more lustrous leaves on shorter petioles give it a more robust appearance. *Sargent's Sylva of North America*, vol. x., 1896, p. 12, &c.

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Ho., Luton.

Cyclanem.—The plants that were raised from seeds sown in September should be pricked off into shallow pans, in a mixture of leaf-mould and sand in about equal parts, then afforded tepid water carefully, and plunged to the rim of the pans in a bed having a heat of 65°. Once a day, if bright, the plants should be lightly syringed, and air afforded in small quantities. Cyclanem plants which are in flower may be assisted with Clay's or some other fertilizer, and be kept in a light house, whose temperature does not descend below 48° at night, nor rise higher than 60° by day.

Freesia.—Those which have passed out of bloom may have a dressing of artificial-manure to assist the formation of the bulbs, if it is intended to flower them next year. Stand the section on a shelf near the glass in an intermediate-house. When the leaves indicate the cessation of growth, gradually withhold water at the roots, afterwards turning the pots on their sides in the full sunshine.

Gardenias.—Those plants with flower-buds set may be given a somewhat higher temperature, and careful watering, but no strong manures, or the flower-buds will be liable to drop off.

Palms.—The amount of artificial heat used during frosty weather favours the increase of insects infesting these plants, and a careful examination of the leaves should be made at short intervals of time for Thrips and red-spider, destroying the first named by fumigation, and the latter by Gishurst's Compound-soap at a temperature of 70°, applied with a sponge. Maintain the Palm-house at 55° by night, and 60° by day. Any plant requiring re-potting may soon be taken in hand, over-potting being avoided. Plants which may have been undisturbed for some years are benefited by weak manure-water being sometimes applied, and occasionally one of soot-water. Other conditions being favourable, this will be all that the Palms require at this season.

Campulales.—Avoid dampness and drip, or decay may set in among those that are being wintered in cold houses or frames. A few specimens of *C. pyramidalis* and *C. p. alba* for early flowering may be placed in a cool house, and brought on gradually, and after a time with a slight advance of heat. After the spikes are well advanced, the energies of the plants may be increased by the occasional use of manure-water; and on no account must the plants become drawn, or the roots lack water. Campanula Melium (Camberly Bells), treated in the same manner make useful subjects for brightening the conservatory, and well repay the labour spent on their cultivation. A few stock plants of *Isohylla alba*, if broken up, the pieces placed in small pots in heat, will soon form graceful subjects for filling baskets, or trailing round the side stages of the conservatory, looking very nice when thus associated with Musk. The plant is of easy culture, and pretty withal.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

Figs in Pots.—Trees that were started in November will now be fast swelling their fruit, and in order to obtain large, fine Figs, these should be freely thinned. If fruits are plentiful all over the trees, not more than one, or at most two, need be left on each shoot, which should be those nearest the base of the shoot, provided these are well developed. All trees so cropped should be given a liberal top-dressing of good loam, a few horse-droppings, and a few half-inch bones, into which the young roots will

quickly enter. Copious waterings of warm liquid manure may also be afforded. Use the syringe freely twice daily in sunny weather, and thoroughly drench the paths, walls, &c., when it is dull, the bottom-heat being kept up to 70° by the additions of fresh materials, and the night temperature should range about 60°, with a rise of 10° by day. Rub out all side-shoots as soon as visible, thereby concentrating the energy of the plants in the right channels.

Succession-houses.—The second house should now be started with a temperature of 50° at night, affording the borders a good soaking of tepid-water, and syringing the trees twice daily.

Figs in later houses should be cleaned, and the branches fastened to the wall, &c., and kept very cool; but exclude frost from the house, and afford sufficient water to prevent the shrivelling of the shoots.

Melons.—As soon heat increases with the advance of the season Melon plants will make rapid progress, and every facility to enable them to reap the benefit of these improved influences should be afforded by keeping the roof-glass very clean and bright, keeping the soil moderately moist, with plenty of moisture in the air of the house, and gradually raising the temperature to 65° to 70° at night if mild weather prevails, but on frosty nights 5° lower than this will be preferable, too much heat leading to an attack of red-spider. Let the bottom-heat remain steady at 75° to 80°, by the addition of fermenting leaves and dung, taking care that the rankness of the manure is exhausted, otherwise the young foliage may suffer. Seeds may now be sown according to instructions given in a previous Calendar.

Cucumbers.—The present is a good time to raise plants to replace those which have borne fruit through the winter. Young plants make rapid progress after this date, soon coming into fruit-bearing, and it is better to plant young plants than to take the trouble to try and renovate old ones. The Cucumbers-house that will be occupied by the fresh plants must be well cleaned before these are put out. The following compost is a good one for Cucumbers: three parts good fibrous loam, one part of prepared horse-droppings, a little lime-rubble, and 4-inch bones added. If the loam be close and heavy, a little leaf-mould or peat may be used with it. Remove the soil to the house some time before planting, that it may get warmed. Make the mounds about 4 feet apart, and these should be rather small at first, to prevent any of the soil becoming sour before the roots have permeated it. Small top-dressings may be given at short intervals afterwards with a better result. For general requirements and continual bearing, the varieties Lockie's Perfection and Telegraph are two of the best. When the plants have commenced to grow freely, they will require abundance of water, and by keeping a temperature of from 60° to 65° at night, and a bottom-heat of 70° to 75°, together with a moist-growing atmosphere, the plants may be kept healthy and fruitful throughout the summer.

THE KITCHEN GARDEN.

By W. PORE, Gardener, Highclere Castle, Newbury.

Early Peas.—The first opportunity should be taken when the soil is workable to sow early varieties on a warm border, or failing that, in the most sheltered quarter of the garden; this sowing will come into use after those sown in the autumn, or in the winter in pots. Some of the early varieties, as Chelsea Gem, Early Giant, or English Wonder should be chosen for the present sowing, for being dwarf in habit the rows may run from 2½ to 3 feet apart, which would of course catch crop coming between, as Lettuce and Radishes. If tall Peas are preferred, a space of from 5 to 6 feet is not too much from row to row, and Kingleader or William I. are the varieties to select. Peas sown in the autumn will probably have reached 1 or 2 inches in height, and should be earthed-up and staked, the shelter thus afforded being of great service. A dressing of fresh soot, or a slight sprinkling of artificial manure along the rows before earthing-up, is also beneficial. The young tops being devoured by sparrows in many gardens, a few lines of black-cotton as a prevent-ive should be stretched along the rows, just clearing the tops of the Peas.

Cabbage, Spinach, &c., sown in Autumn.—Look out the Cabbages planted in the autumn, filling up vacancies from the seed-beds, and then afford the Cabbage-partur a dressing of guano, soot, or some

suitable artificial manure, and stir the had with a hoe or digging-fork. Spinach which has afforded gatherings will derive benefit from similar treatment, and will then afford other pickings in the early spring months, when other green vegetables are usually less plentiful. Beds of Lettuce on warm borders should be cleared of the decayed leaves, the surface stirred with a hoe or hand-fork, and vacancies made good from the reserve plants; or, failing these, by taking up an outside row or two for the purpose, as besides the waste of room caused by patchy crops, they have a slovenly appearance.

Root-stores, &c.—The root-store should be examined, decaying roots removed, and fresh growths starting from the crowns of Beetroot, Carrots, &c., broken off. Parsnips, Salsify, &c., left in the ground in the autumn should be lifted and stored in sand in a cool shed, thus affording the opportunity to the gardener to dig and manure the land. Onions in store should have the decaying bulbs removed, and those starting into growth put aside for present use, otherwise planted thickly in rows 1 foot apart to afford tops for kitchen use in early spring.

Carrots, Kidney Beans, &c.—As soon as the earliest sown Carrots show through the soil, slight ventilation should be afforded in favourable weather, and the soil sprinkled slightly with soot, to deter slugs molesting the plants. Thin the plants before drawing takes place, leaving them about 2 inches apart. Continue to make up hot-beds for early salads, vegetables, &c. A good sowing of Kidney Beans may now be made, as with the increasing sunshine and length of the day, forcing is much easier. The Kidney, or French Bean, needs a better heat of 65° F., and a top-dress of lime in addition of these figures. When potting, let the soil be rich and nicely warmed, and the potting of the plants very firmly done. When the plants are making roots freely, afford them plenty water.

THE ORCHID HOUSES.

B. W. H. WHITTE, Orchid Grower, Burford, Dorset.

East Indian-house.—Plants of *Oncidium applanatum* and *O. a. major* are now showing their flower-spikes, and should be given a warm moist atmosphere. Cockroaches and woodlice must be sought after and destroyed, or the spikes may be devoured before the grower is aware that they are showing. To avoid this, the plant may be suspended from the roof, and immediately the flower-spikes are seen, they should be protected by a bag of wadding. Place some pieces of potato in the compost, and examine them night and morning, for the woodlice; and the cockroaches may be destroyed with beetle-poison. For some time past, this species of *Oncidium* has been given but little water, and it must now be afforded sufficient to keep the roots moist. *O. Lancanum* is a very handsome species of difficult cultivation. We have been informed by various collectors that in its native habitat (Surinam) it is generally found growing on trees in shady places, and in hot, moist situations, in company with the rare *O. hemistichium*. Both species are now commencing to grow, and may be top-dressed or repotted. Watering must always be practised with great care, and if possible, the water should be prevented from touching the rhizomes of the plant or the base of the leaves, which are liable to become spotted from this cause. In the early morning, the foliage may sometimes be seen covered with condensed moisture, which should be removed with a sponge. *Stauropis lissoclioides*, better known as *Vanda Batemanii*, is now producing strong flower-spikes, and should be afforded more water at the root, and exposed to all the light possible. The same remarks apply to the curious *Araucaria (Vanda) Cathcartii*, which has been showing its bloom-buds for several weeks past. *Vanda ocellata*, which has frequently proved very difficult to grow satisfactorily, should be placed during its period of growth in the lightest position in the house, suspending it in a teak-basket near to the roof glass. The plant requires abundant root-moisture during growth. The flower spikes will soon appear, and when the flowers are ready to expand, the plant may be removed to the drier atmosphere of the Mexican-house. Several varieties of *Phaius*, as *Phaius acuminatus*, *P. grandifolius*, *P. Blaneyi*, *P. Wallichii*, *P. bicolor*, *P. Sanderianus*, and the beautiful hybrid *P. Cooksoni* are now making their flower-spikes, and require plenty of root-moisture, and an occasional dose of weak liquid cow-manure.

In the *Intermediate-house*, *Coleogyne cristata* and its varieties should be afforded the same kind of treatment as that recommended for *Phaius* until the flowers commence to open. *Celia bella* is a very

pretty species, and its dwarf funnel-shaped flowers have a pleasing fragrance. This species and *C. macrostachya* may be repotted as they pass out of bloom. They should be grown in well-drained pots in a mixture of peat and sphagnum-moss, and placed in the coolest part of the house. They are plants requiring very careful watering at all times. The second variety, *C. Bauriana* requires a temperature equal to that of the West Indian-house; otherwise, it should be given the same treatment as the other species.

Besnoisii are botanically interesting, but are not so popular as species which possess showier flowers, though several of them are well worth growing, especially where out flowers of an enduring nature are required. Such varieties as *B. verucosa*, *B. Girardiniana*, *B. caudata*, *B. brachiata*, *B. Lawrenceana*, and its major variety *busiginiana*, are now starting to grow, but they should not be repotted until new roots are seen to be pushing from the base of the young growths. They may be grown in pots filled to three-fourths of their depth with drainage. Fibrous peat and a little moss are good rooting materials for them. Keep the plants well elevated above the rim of the pots, as the bulbs are liable to become spotted through close contact with the compost. Place them in the driest part of the intermediate-house, and water sparingly until the flower spikes show.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

The Protection of Blossoms of Apricots and Peaches.—The time is at hand when Apricot and Peach blossoms will require to be protected from frosts, and protective material should be provided ready for use a week or two hence. The best temporary protecting material that I am acquainted with is canvas, such as the XL All No. 5 Hexagon, two widths consisting of 51 inches and 54 inches sewing together. This material should be fixed up with broad tape, stretching lengths of the same crosswise at intervals of about 10 feet the entire length of the cloths. On to these fasten about nine rings, through which and the pulleys to pass the sash-lines for the purpose of raising and lowering the cloths when necessary. I have used this kind of material for Apricots, Peaches, and Green Gage Plums for twenty-five years with satisfactory results, the fruits having set so thickly on the trees as to render severe thinning necessary. The blinds, as already stated, are raised and lowered by means of sash-lines and pulleys, fixed in the following manner:—A series of light poles, varying from 3 to 4 inches in diameter at the bottom to 2 inches at the top, the latter having a slice 1 inch thick, and 3 inches deep, cut off one side to screw strips of board of the same dimensions to, on which to secure the canvas and screw-pulleys and hooks for raising and looping up the blinds to by means of short lengths of stout string provided for the purpose. These poles are let into the ground a few inches at about 6 feet apart, the tops (round side) being secured in suitable holdfasts (Y), driven into the wall immediately below the coping, and against the face of which the several poles rest; and screwed thereon are shouldered straps of iron 1 inch wide, and $\frac{1}{2}$ of an inch thick, rounded on one side, with a bolt and nut on top, and on to these boards, about 14 inches wide, and provided with $\frac{1}{2}$ inch circular holes, are fastened by means of oblong washers and nuts, the former being placed between the latter and the wood. Hooks are driven into each pole 9 feet down from the top, to secure the blinds to when let down. This is very necessary, as wind rising at night would otherwise do much damage to trees and blinds. The poles, boards, and cloths referred to above will last for several years if stored away in the dry when not in use. They are easily put up and easily taken down. While coping-boards, alone used in the manner indicated, make a fairly good protection to extended fruit-blossoms, as it is the downward direction of frost that does the mischief. Fish-nets, doubled or tripled in thickness, if hung up in front of the trees, may be had recourse to where nothing better is available.

Arrows of Work. in the way of planting and pruning of trees, Currant and Gooseberry-bushes and Raspberry-canec, should be finished, where the frost has relaxed its hold on the ground. Trees and bushes which were planted before the frost set in, should have the soil made firm about the stems where necessary, staking standard trees and others requiring support, to maintain them in an erect position. If not already done, paint the stems up 2 feet from the ground with a mixture consisting of clay, soot, and

cow manure, mixed to the consistency of thick paint, as a means of preventing rabbits and hares gnawing the bark. The canes of autumn bearing Raspberries should be cut down to within about 2 inches of the ground.

THE FLOWER GARDEN.

By CHARLES HERRIS, Garbeur, Dringmore, Maidenhead.

To Cut Down Shrubs.—At the time of writing, snow and frost are chinking much of the out-door work of the season; still, advantage may be taken of days when neither snow nor rain fall to reduce the size of over-grown shrubs, cutting the branches hard back. Laurels are much benefited by this hard pruning, and may be cut down nearly to the ground. This has the effect of forcing into growth a mass of shoots at the bottom, as the stems break freely. Equally so, *Rhododendron ponticum*, and others on their own roots, may be similarly treated, these also pushing out an abundance of shoots from the stems and branches. It frequently happens that the choice varieties which are grafted on *R. ponticum* get over-grown with shoots of the latter. It is usually an easy matter to distinguish the *ponticum* growths, and remove them entirely by a vigorous downward pull, which is preferable to sawing or cutting with a knife or bill-saw, although large branches must be removed with the saw. The *Rhododendron*, when it thrives, is not harmed by severe pruning, and the after-growth being quick, a specimen bush that has been severely cut, although not sightly-looking at first, soon becomes well furnished with shoots. Most kinds of shrubs may be thus cut back, including Hollies, both green and variegated-leaved, and in this respect they may be treated like the common Laurel. The *Thuus* and *Cupressus*, Yew, green and golden; *Raphiodes ovatus*, *Phillyrea*, hardy *Heaths*, and *Tyrus japonica*, bear pruning with impunity. The first two make capital garden hedges, and may be clipped once a year, just like white-thorn. After and during heavy falls of snow, the Conifers and other trees and shrubs upon which it accumulates should be gently eased of their burden. The branches of ornamental Conifers, &c., which sweep the ground, and all newly-planted trees should be surrounded with rabbit-proof wire during hard weather, or much harm may be done where hares and rabbits are found. This wire-netting ought to be at the least 2 feet high, and made secure with neat stakes or iron-rods. If a fence of this kind is to remain round a tree for several years, it should have a strip 6 inches wide at the bottom bent at right angles, and buried 6 inches deep; the reason for which is that the rabbit begins to burrow under a fence close to it, and soon coming on the up-turned strip, through which it cannot make its way, it then desists from burrowing. When the fence is made in this wise, the wire must be wider than 2 feet, or two strips used instead of one.

Olives and Irises, &c.—These plants may now be placed in more heat, and the propagation by means of cuttings commenced as soon as the tops get of sufficient length. Heliotrope, Ageratum, and Tropæolum, may be similarly treated, with the exception of a rather lower temperature suitable for these; moreover, they may be increased more freely later on. Stock plants of *Verbena* should be potted or boxed, and placed in a warm house, the tops being taken for cuttings after growth has progressed a little.

PHYSIOLOGICAL DIAGRAMS.—In these days of horticultural schools, a good set of diagrams, illustrative of the principal facts in vegetable physiology, as a desideratum. This has been supplied by Professor PERREA and Dr. E. LAURENT, of Brussels (WILLIAMS & NORWICH, London). The plates appeal to students of all nations, but for the benefit of the students using different languages, the explanations of the figures are given in German, French, and English. The plates are devoted to the physiology of nutrition only, as the phenomena of reproduction are already well represented in similar collections. The plates in question are 70 x 80 centimètres—none too large for a class room. The first plate is devoted to a graphic representation of the proportionate amounts of different kinds of food taken up by the roots. Then follow plates devoted to respiration, assimilation, transpiration, parasitism, fermentation, carnivorous plants, root tubercles of *Leguminosæ*, growth of roots, stems, influence of gravitation, light, climbing plants, movements of plants, and variation as represented in the forms of Calceolæ. The plates are well selected, and tell their story so effectively, that we recommend them for all garden schools and similar institutions.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	FEB. 9	Royal Horticultural Society's Com. mt. 10.15. Annual General Meet.
WEDNESDAY,	FEB. 10	Rondeletian Gardeners Meet
SATURDAY,	FEB. 13	Royal Botanic Society Meet

SALES.

MONDAY,	FEB. 8	Tuberous Spices, Paeonies, Gladioli, &c., at Protheroe & Morris' Rooms.
		Border Plants, Bulbs, Lilies, &c., at Stevens' Rooms.
TUESDAY,	FEB. 9	Caranations and Painters, Iris, Anemones, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	FEB. 10	Japanese Lilies, Azuleas, Standard and Dwarf Roses, Begonias, &c., at Protheroe & Morris' Rooms.
		Roses, Fruit Trees, Shrubs, Border Plants, Bulbs, Roots, &c., at Stevens' Rooms.
THURSDAY,	FEB. 11	Hardy Perennials, Lilies, Spices &c., at Protheroe & Morris' Rooms.
		250 cases of Lilium from Japan, 27 cases of Arucisriscus, 500 lots of Border Plants, &c., at Stevens' Rooms.
FRIDAY,	FEB. 12	Lilies, Begonias, Hardy Bulbs &c.; Imported and Established Orchids from Messrs. F. Sander & Co., at Protheroe & Morris' Rooms.
		Scientific, Photographic, and Miscellaneous Property, at Stevens' Rooms.

AVERAGE TEMPERATURE for the closing week, deduced from Observations of Forty-three years, at Chiswick:—39.7°.

ACTUAL TEMPERATURES:—

LONDON.—February 3: Max., 44°; Min., 35°.
PROVENCE.—February 3 (6 P.M.): Max., 56°; Sully; Min., 32°. Aberdeen.

Economic Botany and its Applications.

OUR neighbours on the other side of the Channel have now a fine opportunity before them of promoting the general welfare and civilisation of the peoples in their recently-acquired protectorate over Tunis. Two circumstances seem specially favourable to them—the experience gained in the neighbouring territory of Algeria, and the fact that French domination in Tunis has been secured peacefully, and without the hatred and distrust of the victors felt by those who have been conquered. Otherwise the conditions appear much the same. The physical geography and climate of Tunis very closely resemble, if they are not identical with, those of Algeria. Arab and Turkish rule have, as in other countries, blighted what was once one of the most productive districts in the old world; and the fact before the French is to fight against the inclemencies of the climate, and remedy the devastation caused by former and present possessors of the soil. The task is undoubtedly a very onerous one; but we have no doubt that, given time and peace, a large measure of success will await the well-planned efforts of the French. The first thing to do is obviously to obtain a complete survey of the country, so as to become familiar with it in all its details, not omitting the laws, manners, and customs of the natives. In this country, authentic information of this kind is too often locked up in blue-books, or other official publications, which do not reach the general public;

but in the case of Tunis, the French have a comprehensive account of the natural features and products of the country in successive numbers of the *Revue Générale des Sciences*.

We call attention to this publication, as some portions of this report are likely to be of interest to our readers, and those who are not immediately concerned will still find the reports interesting reading. The first article of special interest to cultivators is one by M. GASTON LOTTI on the forests of Tunis. These, for climatic and other reasons, were never very extensive, but there is clear evidence to show that they were greatly more so than at present. An immense tract of Olives and Almonds, extending from Algiers to Morocco, was destroyed for military reasons. The recklessness of the Arabs, forest fires, and especially the goats, are responsible for much subsequent loss, and these evils the French, who are good foresters, are setting themselves to remedy. The Cork-Oak, the Aleppo Pine (*P. halepensis*), Evergreen Oaks, the "Thuya"—by which the writer, no doubt, means the *Tetradlepis articulata* (syn. *Callitris quadrivalvis*), which furnishes beautifully marked and durable timber—and Olives, are among the most useful trees, and their management has been undertaken by the State, the first duty being the construction of roads, and the formation of trenches to check the progress of the forest fires. The preservation of existing forests is an easier matter than the formation of new ones. Seed has to be sown again and again to compensate for the destruction of the young seedlings by drought, fire, goats, and moving sand, so that re-forestation by means of seedlings has had to be abandoned. M. LOTTI concludes his report by saying that the northern forests already supply an important source of revenue, the soil of the oases becomes less mobile, and a beginning has been made in the solution of the problems connected with re-forestation.

The same report contains a very interesting notice on acclimatisation in Tunis, by Mr. MAX CORNU, the Director of the garden of the Museum in Paris. We need not stop here to discuss the meaning properly belonging to the word acclimatisation, but take it in the sense in which it is generally used by practical men. M. CORNU has had a comparatively easy task. The opposite shores of the Riviera, the labours of NAUDIN and of the late Baron VON MUELLER, afford both examples and precepts applicable to the present case. M. CORNU divides the country for his purposes into the mountain zone of the Apple and the Pear, with a climate like that of Central France, the zone of the Olive recalling the climate of Provence, the zone of the Orange, where the *Eucalypti* may be planted, as at Nice and Cannes; the zone of the Date-Palm comprising the oases. These zones, of course, overlap, and are modified by local conditions—drought, heat, wind, and moving sand being the chief evils that have to be met. In order to develop and extend the resources of these regions, an experimental garden has been established in the vicinity of Tunis, to cultivate plants likely to be serviceable, and to supply the natives and colonists with plants, cuttings, grafts, &c., of plants of economic importance.

One great difficulty in the way of the garden arises from the operation of the Phylloxera laws, which here, as elsewhere, by their misplaced rigour have caused an entirely unnecessary amount of loss. "Aucune plante ne doit entrer en Tunisie." The universal failure of such laws to prevent the introduction of the

Vine-louse is surely sufficiently obvious to ensure the speedy modification of these restrictions. Till this is done, seeds constitute the only means by which useful plants can be introduced. Among the Oranges and other fruit-trees, may be mentioned, as thriving under proper care in Tunisia, Bananas, Custard-Apples (*Cherimoya*), Casimiroa, Avocado Pears, Litchies, Tree Tomatoes, and Persimmons. As shade-trees, *Ficus macrophylla* is recommended, and *Phytolacca dioica*, which attains an enormous size, and which astonishes visitors to the Riviera who are accustomed to see it at home as an herbaceous perennial. Protection against wind is secured by plantations of *Acacia cyclops*, *eburnea*, *Farnesiana*, &c., behind which *Casuarinas* may be utilised. Among industrial products, the Sugar-cane is failing in the competition with Beetroot, and this in French territory furnishes a curious subject for reflection! The circumstances are not favourable for the cultivation of Cotton, but fibre-plants like Sisal-hemp and various Agaves would thrive in Tunisia; and in the oases, no doubt much might be done in the cultivation of the better varieties of the Date-Palm.

We need not make further comments upon this interesting report beyond saying, that it furnishes an excellent illustration of the important services that botany and horticulture, which the public are apt to look on as mere matters of recreation or amenity, can render in the development of the resources of a country. In our own country, colonial interests have been made the subject of special study at Kew, beginning with Sir WILLIAM HOOKER, growing vigorously with his successor Sir JOSEPH HOOKER, and continually showing expansion under the present directorate. In the future, as in the past, statesmen will need the co-operation of the men of knowledge, and the men of practice, in order to make the most of the territories over which they hold sway.

"SOME interesting particulars concerning the management of Epping Forest appear in the annual report of the Epping Forest Committee of the Corporation. The moderate thinning of the over-crowded woodlands has been continued, the work consisting of the removal of inferior stems which injure those of more picturesque growth, or which interfere with the healthy development of the undergrowth and saplings. In future, the preservation of the natural beauties and features of the forest will be maintained by the non-removal of trees overthrown by the wind and those of a larger growth which die. The shooting of wild birds has been stopped, and the number of wild ducks breeding at Wanstead has greatly increased. In the early part of last year it was resolved to take a census of the deer, and the operation proved one of considerable difficulty, but out of four censuses three were practically identical, and these indicated that the fallow deer number about 130, and the roe deer about thirteen, a large increase." *Westminster Gazette*, February 1, 1897.

The lines in italics are our own, and point to a mischievous practice not favoured by foresters who have charge of forests and plantations in civilised countries. To permit dead and decaying timber to remain any longer in a forest than is absolutely necessary is simply to afford breeding and hiding-places for insects injurious to trees, and centres from which many species of fungi inimical to the life

FIG. 26 — ROSE-ARCADÉ IN PLEASURE GROUND OF LUTON DRO. (SEE P. 95.)

and well-being of trees may spread to those which are sound. Of these injurious vegetable parasites we may merely mention *Nectria cucurbitula*, whose host-plant is usually the Spruce, and more rarely *Soots Pine*, *Silver Fir*, &c. *N. ditissima*, the cause of canker in the Apple, attacks Hornbeam, Hazel, and Beech; *N. cinnabarina*, whose mycelium penetrates into all the elements of the wood, decomposing the starch, in consequence of which the wood turns black. The Oak is subject to many forms of canker, of which it will suffice to mention *Aglotyspora Tulesta*, which attacks the smooth cortex of Oaks under forty years of age, causing it to die in patches. "A year afterwards," remarks HARTIG, in his *Diseases of Trees*, "numerous round or oval cushion-like stromata appear in the dead cortex. Later on these break through the periderm in one, two, or three places, further developments follow, and trees so attacked succumb in large numbers, rendering frequent felling and strong thinning necessary" as a means of preventing infection. We have said enough to show that the authorities responsible for the preservation of Epping Forest, cannot avoid the work of felling and clearing out the dead and dying trees, even if by so doing they offend the æsthetic susceptibilities of some of those who all unconsciously would make a wilderness and call it peace.

LINNEAN SOCIETY.—On the occasion of the meeting of the society, January 21, Mr. C. B. CLARKE, Vice-President, in the Chair, the Secretary read a letter from Mr. J. Y. JOHNSON, of Funchal, Madeira, commenting upon Dr. D. MORIS's exhibition (November 5) of raphides composed of oxalate of lime in the bulbs of Hyacinths, the handling of which had produced a form of eczema. Mr. JOHNSON mentioned a parallel case in *Richardia æthiopica*, a beautiful Aroid known to gardeners as the Lily of the Nile. The raphides at Funchal had tried to utilize the starch obtainable from the corns, but complained of the irritation in the hands produced by it, which, on examination, was found to result from the presence of numerous needle-shaped raphides, as in the case of the Hyacinth-bulbs referred to.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society will take place in the Drill Hall, James Street, Victoria Street, on Tuesday, Feb. 9. The various committees will assemble at noon as usual, and at three o'clock the annual general meeting of the society will be held at the Society's offices, 117, Victoria Street, Westminster, S.W.

"KEW BULLETIN."—The January number contains a list of the publications more or less directly emanating from Kew since its establishment on its present footing in 1841. The arrangement is chronological, an inconvenience not compensated for by the presence of an index of names and subjects which we hope may be supplied on another occasion. The selection, if anything, errs on the side of over-elasticity; at the same time we note a few omissions. In any case it is a wonderful record, of which the Kew staff may well be proud.

THE ROYAL GARDENERS' ORPHAN FUND.—At a meeting of the Executive Committee, presided over by Mr. W. MARSHALL, the following special donations to the Fund were announced: Leeds Paxton Society, £3 5s.; Tonbridge Gardeners' Society, box £2 6s.; Mr. G. FRY, Hither Green, Lewisham, box £1 2s. 6d.; A. CHANCELLOR, Esq., Richmond, £1; Mr. THOS. WILKINS, Henstridge Gardens, Bradford, 10s.; Mr. G. SMITH, Kenley, 5s.; Mr. C. LAWTON, Brough, 5s.; and "A Youth from Ayr," 2s. 6d. The draft report and financial statement were considered and agreed to, and passed for presentation at the Annual General Meeting at

Aberton's Hotel, on the 19th inst. It was announced that Mr. OWEN THOMAS, Frognore, would take the chair at the usual dinner on the evening of the annual meeting, at 6 p.m.

THE RETIREMENT OF MR. DAVID THOMSON FROM DRUMLANRIG.—We understand that Mr. DAVID THOMSON will in May vacate the post of head gardener to His Grace the Duke of Buccleuch at Drumlanrig, a post which he has held with distinction for twenty-nine years, and will in future reside in Edinburgh. Mr. THOMSON's successful career as a horticulturist and a manager of these princely gardens, also of those at Archerfield, and during his earlier years in England, is pretty widely known in the gardening world. He has accomplished much in every branch of horticulture, and in every detail of garden management. Mr. THOMSON's urbanity, kindness, and high character, his helpfulness to all who sought his aid and advice on matters of importance as well as on gardening, were equally well known and appreciated. He has written much, and with great lucidity, on most branches of horticulture, and his gardening works are greatly valued by his numerous readers. The Duke of Buccleuch, who, together with the family, are loath to part with him, have made kindly overtures to him to remain at his post; but though his bodily and mental activity are not impaired, his advancing years have to be considered. Mr. DAVID ISBETS, head gardener to Lord Grey, Howick Hall, Lesbury, Northumberland, has been selected to succeed Mr. THOMSON. Mr. ISBETS has been about 20 years at Howick, and was for some time previously at Powerscourt. He is a very able, all-round gardener (now in the prime of life), and well merits the choice which has been made.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, February 8, when a paper will be read by Mr. J. W. WILKES BOND (Associate), entitled "Allotments and Small Holdings." The chair to be taken at 8 o'clock.

WINCHESTER GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—On Tuesday, the 26th ult., Mr. P. H. FOLKES, B.Sc., M.R.A.S. (of the University Extension College, Reading), gave a lecture on "Insects injurious to Plant Life, and how to Deal with them," the lecture being made unusually interesting by the different subjects exhibited by means of lantern slides. The principal subjects were the winter-moth, cod-worms, and weevils.

ANNUAIRE GENERALE HORTICOLE.—The publishers of the *Jardin*, 167, Boulevard Saint Germain, Paris, have issued a directory containing the list of members and the statutes of the Central Syndicate of Nurserymen of France. In addition, there are lists of all the horticultural societies of the country, according to the departments in which they are situated, and of the nurserymen, seedsmen, and other tradesmen connected with horticulture, arranged according to departments, and also alphabetically. A few English firms are mentioned, but we think few would recognise the great Grange cultivator nor his address under this entry, "KAY,

Peter E.," in which the first word is in the position allotted to the locality, and the second in that assigned to the name!

ROCK GARDENS.—Recent numbers of MÖLLER'S *Deutsche Gärtner Zeitung* contain numerous illustrations showing the very effective manner in which M. COMAROU arranged his collections of alpine plants at the recent Geneva exhibition. Rocks, waterfalls, picturesque chalets, *tout vraisemblance* to the exhibition, whilst the collection of species was remarkable for its extent and condition.

DUNES.—The American Holly, *Ilex opaca*, grows in the vicinity of the Dunes of New Jersey, and is recommended to be propagated by seed in these sands, when they have become fixed. *The Forester*.

"LA SEMAINE HORTICOLE."—It is our pleasing duty, metaphorically, to lift our hat, and extend our hand in friendly salute to the new horticultural venture, M. LUCIEN LINDEN, whose energy seems inexhaustible, has now launched his weekly garden

newspaper in the French language. It is founded on the plan of the English horticultural journals, and, like them, embraces all departments of horticulture, the contents of the first number, always the most difficult, being very varied. The *Journal des Orchidées*, with all its smartness, and the *Illustration Horticole*, will be "englobed" within the columns of the *Semaine*. We wish our colleague all the success the enterprise deserves.

BOTANIC GARDEN, TRINITY COLLEGE, DUBLIN.—Among the interesting plants now in bloom are *Trochetia Blackburniana*, a *Stereocaulon* plant from Mauritius; and the pretty Composite, *Barnadesia rosea*, allied to the Mutisias.

HORTICULTURAL CLUB.—The twenty-second anniversary dinner will be held at the Hotel Windsor on Tuesday, February 9, when the Chairman of the Club, Sir J. D. T. LEWELYN, Bart., M.P., will preside.

THE WOLVERHAMPTON FLORAL FETE.—From a general statement of accounts just issued, we learn that the income for the year 1896 was £2302 5s. 7d. Subscriptions realising £266 8s. 6d.; sale of tickets and admissions paid, £1657 11s.; and from other sources the sum of £373 3s. was received. The profit on the year is £433 5s. 7d. Among the items of expenditure is bands, £199 19s.; and fireworks, £148 13s. 8d. It is the two latter items especially which entice the throngs to visit the show, though a very large and really magnificent exhibition is provided. The committee have paid out of their profits, £632 3s. 9d. to the committee of the Queen's Park and Baths, for shelters, greenhouses, &c., from 1889 to 1894, and they paid £1062 18s. for the erection of the fine conservatory in the West Park. They have the sum of £1818 15s. 3d. invested, and have purchased at various times permanent plants to the value of £177 2s.

THE EALING HORTICULTURAL SOCIETY.—The annual meeting of this Society was held on the 21st ult., and the report of the committee went to show that, despite the wet weather experienced on the day of the summer show, and the counter attractions on the day of the Chrysanthemum exhibition, yet a substantial balance, according to the Treasurer's statement, is carried forward to the present year. It was resolved that the summer show should take place on June 30, and the Chrysanthemum exhibition on November 3. Messrs. A. G. DIXON and GEORGE CANNON were appointed joint Hon. Secretaries.

"POPULAR BULB CULTURE."—By W. D. DRURY (L. URCOTT GILL, 179, Strand). At the low price of a shilling this "handy guide to the successful culture of bulbous plants both in the open and under glass," will prove both attractive and useful to every one who loves his garden and greenhouse. It is, naturally, intended for the masses, rather than for specialists, who would prefer a more ambitious work. *Popular Bulb Culture* is arranged alphabetically, and its distinguishing title is used in its widest sense. An index aids the reader in his work, which is rendered still more agreeable by the inclusion in the book of many illustrations.

WOLVERHAMPTON HORTICULTURAL CLUB.—A monthly meeting was held on February 2, at the Midland Café, when Mr. G. BURROWS, Berwick House Gardens, Shrewsbury, read a paper upon "Orchids." The essayist touched briefly upon the structure and habitats of some of the genera, and dwelt more fully upon details of culture.

GENERAL HORTICULTURAL EXHIBITION AT HAMBURG.—Notwithstanding the delay in issuing the plan and programme of the scientific section of this exhibition, a considerable number of botanical and zoological objects have been received from Germany and foreign countries; and notices from intending exhibitors have already reached a surprising number.

PUBLICATIONS RECEIVED.—The following publications have reached us from the United States Department of Agriculture, Division of Entomology:

Bulletin No. 6, *Proceedings of the Eighth Annual Meeting of the Association of Economic Entomologists*, containing papers among which are the following:—The Evolution of Economic Entomology, C. H. FERNALD; Some Temperature Effects on Household Insects, L. O. HOWARD; A New Insecticide (arsenate of barium), A. H. KIRKLAND; Scale Insects and their Enemies in California, J. B. SMITH, &c.—*Bibliography of the more important Contributions to American Economic Entomology*, prepared by SAMUEL HENSHAW. Part V. L-Z. The concluding and index volume of a useful publication.—*A Bacterial Disease of the Tomato, Egg-plant, and Irish Potato*, by ERWIN F. SMITH. This Bulletin deals with *Bacillus solanacearum*, n. sp., and of different conditions under which the pest is favoured or can be combated against. It is illustrated with coloured and other plates.—We have also before us Nos. 21 and 22 of *Favourite Flowers of Garden and Greenhouse*, by EDWARD STEF, F.L.S. This work, previous numbers of which we have had occasion to notice, is progressing satisfactorily, the latest page of it dealing with *Immortelles* (*Helichrysum*). The accurate and attractive plates will commend the publication to the many who consider no book complete without such additions.

LUTON HOO PARK.

WHEN recently visiting this grand old place, I was much struck with the great improvements that have been carried out there during the last year or two. Madame de Falbe, the owner, has good reason to be proud of this estate. The present house was erected in 1843, the old mansion having been twice destroyed by fire, and risen, Phœnix-like, from its ashes. It formerly belonged to Lord Bute, and was, after changing hands once or twice, purchased by the late John Shaw Leigh, Esq., who restored and decorated the building; and after his death it passed into the hands of his son, Mr. Gerard Leigh, the first husband of the present proprietress. The park contains about 1500 acres, and the river Lea, which runs through the lower portion of the estate, is widened out so as to form an extensive lake, which forms an attractive feature, especially when viewed from the house.

The pleasure-grounds, which are about 100 acres in extent, are well laid-out, and contain some fine specimens of trees and shrubs. Portugal Laurels seem to revel here, some of the clumps being as much as 15 to 18 feet high. There are some very pretty little woods, which have been turned into small gardens of the Italian style; many fine and valuable statues have been introduced here, and great care has been exercised in the planting of Roses and climbing plants, which are skilfully trained to form bowers and various designs (see fig. 26).

The flower-garden contained last summer some extensive beds of fine-flowering tuberosous Begonias, as well as other popular bedding plants. I was much pleased with a large bed of Crozy's dwarf Cannas, which were full of bloom. Mr. Maycock, the gardener, has evidently found out the way to treat these handsome plants, for a better lot I have never seen in the open. There are also here grand borders of herbaceous plants, which have been well planted, great care having been bestowed on the selection of species and varieties.

Leaving the flower garden, I was conducted to the kitchen-garden, which is 6 acres in extent, and well walled in; it contains a fine collection of fruit-trees, these both on the walls and in the quarters being in excellent condition. There was a capital crop of fruit last year, and many new and meritorious kinds have been recently planted. Strawberries are grown to a great extent, and 2000 potsful are forced yearly. Chrysanthemums are also extensively grown. Carnations, too, are a great feature, 2000 plants being grown in pots, and a very large number planted out in the borders; C. Souvenir de la Malmaison are well done, and the whole stock at the time of my visit was free from disease. There is a spacious range of plant-houses, vinerias, and Peach-houses also; in the stove some fine Crotons, Alocasias, Dracenas, &c., were on

view; the collection of Palms is large, some fine specimens of Kentias being specially noticeable. Azaleas, too, are grown largely; in fact, most of the things taken in hand by Mr. Maycock are done well, and it must be very gratifying to him to receive the encouragement he does from his employer, through whose generosity he visited the Riviera in January, 1895, when he had an opportunity of comparing notes and of visiting the beautiful gardens in that favoured district. Madame de Falbe has a large villa at Cannes, and takes great interest in acclimatizing many of her favourite plants in that climate. Henry Williams.

MASDEVALLIA CORIACEA, LIL.

This is a very old Masdevallia, having been discovered by Theodor Hartweg, one of the Royal Horticultural Society's collectors in 1842, on the hills

FIG. 27.—MASDEVALLIA CORIACEA. (Colouring of flowers white, creamy-yellow and purple.)

of Montserrat, near Bogota. It was subsequently found by other collectors, including John Linden, Schim, Karsten, and Weir, in the same neighbourhood, at elevations varying from 7000 to 9000 feet. It does not, however, appear to have been introduced to cultivation until 1871, when it was distributed by Messrs. H. Low & Co., of Clapton, as *M. Bruchmulleri*, in the belief that it was a new species discovered by their collector Bruchmuller. In construction it approaches *M. civilis*, *M. leontoglossa*, and *M. velifera*; but it is nevertheless quite distinct from all of these in many respects.

As will be seen from the accompanying sketch, made from one of Messrs. Sander & Co.'s plants shown at the Drill Hall on July 10, 1896, the flowers are by no means minute (fig. 27). The perianth (calyx) tube is very fleshy, and of a creamy greenish-yellow inside,

the outside being washed with purple-brown at the base, and decorated with a few rows of purple dots. The conspicuous white petals have a crimson line in the centre, almost from base to apex; while the lip is pale green, minutely tubercled in front, and has three brownish-green longitudinal stripes on the surface. The leaves are very leathery, 6 inches or more in length, with purplish speckled petioles, and the slender scapes are pale green, dotted with purple, as are also the rather large bracts.

It may be interesting to quote the following remarks by Consul Lehmann, from the Marquis of Lothian's important publication, the *Gaons Masdevallia*. He says:—"M. coriacea grows on sandstone rocks, upon which thin layers of soil and decayed leaves have accumulated, and is found along the western border of the Savana de Bogota, at an elevation of 2500 to 2650 metres (about 8125 to 8612 feet). It is plentiful in the vicinity of Bojaca, Facativita, Tres Esquinas, and Subachoque, and in all these localities, it is exposed to severe changes of climate—sun, rain, and strong winds. The annual average temperature of this region is between 13° and 15° Centigrade (about 55° to 59° Fahrenheit)." *John Weathers, R.H.S., London.*

NOTICES OF BOOKS.

CONFIDENCES OF AN AMATEUR GARDENER. By A. M. Downsinh. (London: Seeley & Co., Limited.)

THIS book is composed of a series of papers which have previously appeared in the *Pall Mall Gazette* under the heading, "Wares of Autolyens;" in their present form they are supplemented with plates of a Japanese-like style. The matter of the letterpress may be guessed from the title of the volume. The author discourses pleasantly of her garden, her experiences, difficulties, and amusements therein. Those who like, as many persons do, a chatty rather than a learned book, and written by one who has committed to paper those little adventures, pleasant and otherwise, which befall all amateur gardeners, will be pleased with these confidences.

FRUIT CULTURE FOR AMATEURS.*

IN writing this manual on fruit culture for the use of amateurs, the author does not follow in the track of most other writers on the subject of fruits and their cultivation for market purposes, whose treatises have issued from the press in some considerable numbers of recent years, and necessarily the space devoted to each kind is more limited. As is befitting so experienced a cultivator, his first chapter treats of the drainage of the land, affording the reader pretty full instructions with regard to the methods he should pursue in rendering the land fit to carry any kind of fruit-tree or bush. Then follows a chapter on planting, advocating, as he was bound to do, either sun face or shallow planting on very heavy soils. Then follows a series of brief chapters on each kind of fruit grown in British gardens, not forgetting Nuts, Filberts, Strawberries, &c. We remark that his list of varieties under each heading is severely limited in number; and, we think, that in view of the fact that some varieties suffer from spring frosts more than others, the amateur will be well advised to be less nice in his choice of varieties, and to learn from his more experienced neighbours the names of the varieties which have been found to suit the locality, as well as to consult his own tastes and predilections, supposing he have any. Under Pears we are pleased to find varieties named which, owing to their fine flowers or their abundance, make admirable decorative trees in pleasure grounds and shrubberies; among these is that seldom seen, but delicious small-fruited variety, Aston Town. No mention is made of the stately, pyramidal, autumn Bercanot. Mention is made of such varieties as look well on the exhibition table.

* By S. T. Wright, Superintendent of the Royal Horticultural Society's Garden, Chiswick, with an Appendix on Insects and other Pests, injurious to Fruit trees, by W. H. Perry. (London: L. Upcott Gill, 159, Strand, W.C.)

The Apple is made to furnish its quota of varieties ornamental when in bloom, among which we find Lord Grosvenor, Dumelow's Seedling, Duchess of Oldenburgh, Warner's King, King of the Pippins, &c. This knowledge of varieties of Pears and Apples which are useful in this way, is peculiar and uncommon. For quick returns, Mr. Wright recommends the bush form, and on heavy land this form on the dwarfing stocks.

In the chapter on Plums, justice is done to the celebrated firm of Rivers & Sons, by including very early and very late varieties of this fruit, which have lengthened our Plum season by a period little short of three months.

Our author rightly insists on the continued cultivation of the Peach and Nectarine in parts of the country south of the Humber, choosing south, west, and east wales for the trees. We think that he might go even further north, and still find these successfully grown—at least, on warm soils and in valleys, and districts not much elevated above sea-level. In this chapter Messrs. Rivers appear as benefactors with their excellent, hardy, early, and late varieties of Peaches and Nectarines. Crimson Galaude is stated to be the best all-round Peach known; and the woolly, flavourless, yellow-fleshed American varieties are very properly condemned. And so on *scrutinium* through all our fruits, Grape-vines, nuts, &c. The various diagrams of training with which the book is enriched will be found of use by those for whom it is written, and who cannot have had any experience in this matter. In the chapter on Diseases, we find that the causer in the Apple is said to be primarily due to twists and wounds, whereas these form only the points of access to the fungus. *Nectria ditissima* is the real cause of rot, which is extremely infectious.

The chapter on Insect Pests by Mr. Drury, contains much instructive matter, and the text is furnished liberally with woodcuts, showing the various insects in one or other stage of development. There are various small lapses that we noticed, but these are of no moment; and we can recommend the Manual to the notice of all amateurs contemplating the cultivation of fruits for home consumption.

HOME CORRESPONDENCE.

AN ANNIVERSARY APPEAL.—When we are in distress how we cry for help, but when we are full with all manner of good things, how seldom do we think of the needy, the fatherless, and the widow! Now in this year of our beloved Queen's reign, all of us seem desirous of having a joyful demonstration of thankfulness for a reign of peace and prosperity. This shows a wise and true national spirit. How many thousands are there who have as yet not begun to give a thought to their needy comrades and sisters, and who, when distress of some kind comes, or the breadwinner is taken away, utter the cry, "I wish I had been more frogal, and given my mite to help the poor widow and orphans of that good, struggling man who has been taken, and who was not able to provide for the needs of those belonging to him." I have long thought, in fact, every Saturday morning I open the paper expecting to see some well-written article praying gardeners to lay this call to heart; and time time would not possibly present itself for a little sacrifice to be made by all the gardeners of the country. And if I could but persuade every gardener in the United Kingdom and Ireland to make this one effort to contribute seven-and-sixpence each this year, what a grand total it would make for the Gardeners' Orphan Fund. I am afraid Mr. Woods's idea is too extravagant to succeed; besides, one of the duties of our craft is charity towards our neighbour, and not thinking so much about our own comfort, but helping those who have no means of helping themselves. *Charles Perry.*

KETELEERIA FORTUNEI.—Your correspondent, "J. B." in *Gardeners' Chronicle*, Jan. 30, p. 71, mentions two specimens of *Keteleeria Fortunei* growing in this country, one at Messrs. Veitch's nursery, and the other at Menally, Par, Cornwall. Many of your readers would, no doubt, like to know if these are

from Fortune's seeds, or young specimens from seed from Messrs. Revelli's tree at Pallauz. In the report of the Conifer Conference, p. 154, the tree is stated to be abundant on the mountains to the north of Fochow, but immediately afterwards the report states that Fortune's specimen is the only one of its kind known in its native country. What authority is there for the former statement? Have cones, &c., from Fortune's tree been introduced since his time. His tree appears to be growing near the scene of the massacre of missionaries on Aug. 1, 1895, supposing, of course, that Kooshan and Kuehng are only different ways of spelling the same place. Probably many missionaries and others have visited the place of late years. *Charles Palmer, 87, Burlington Street, Manchester.* [Harris found the tree abundant in the mountains to the north of Fochow, see *Masters in Journ. Linn. Soc.*, vol. xxii (1886), p. 197.—Ed.]

CYPRIPEDIUM INSIGNE SANDERÆ.—In last week's issue of your paper, in an editorial note to a letter written by "S. S." on the subject of "Cypripedium insigne Sanderæ," you make the following statement:—"There are not two varieties of Cypripedium insigne Sanderæ, though possibly the allied but inferior Cypripedium insigne Sanderianum and other similar inferior varieties may have got confounded with it." This is incorrect. I have a plant of *C. insigne Sanderæ* which I purchased from Messrs. F. Sander & Co. some four years ago, and which was imported by them later than the original plant. There can be no doubt as to my plant being "Sanderæ," and it is equally certain that it is different in several respects from the original plant, or as it is now commonly called "Baron Schroder's variety." I showed flowers from my plant before the Orchid Committee last year and the year before, and on neither occasion did I hear of a doubt being raised as to their being true to name. In the opinion of several well-known Orchid experts the flower of my plant is superior to that of Baron Schroder's var. In order that the merits of the two varieties may be fairly discussed, I purchased last year, in flower, a plant of the Baron Schroder variety about the same size as my plant (some twelve growths). These plants are growing side by side in my Cypripedium-house, under exactly the same treatment, and when they are next in flower, I purpose bringing both plants before the Orchid committee. I had the flower which I brought before the Orchid committee last year painted by Mr. Macfarlane, and I have an exact copy of a painting by the same gentleman of a flower from Baron Schroder's plant. If you are sufficiently interested in the subject, I shall be pleased to forward these for your inspection. I shall be obliged if you will insert this letter in your next issue. It may perhaps assist in clearing up what appears to be a somewhat vexed question. *G. Sherwell Ball, Ashford, Wilts.*

Your correspondent, "S. S.," seeks to know more about my plants than I can supply. I have never shown my *C. Sanderæ*. I sold to Mr. Low a plant in flower, and I believe Mr. Warburton has flowered a plant which I sold him. I have shown a form of *C. Sanderianum*. The plant of *C. Sanderæ* was sold by Messrs. Sander & Co., and bought at public auction by me at the Pickering Sale for £27. I have compared the flower for two seasons with the flowers kindly sent me by Baron Schroder, and have found them alike, except that my flower was not quite so large. This will be owing to the plant having been broken up. Perhaps your correspondent is like a gentleman who saw one of the Baron's flowers in Manchester, and said it was a very poor form, and not at all like the Sanderæ he had seen at The Dell. Perhaps your correspondent's assertion might carry more weight (or less) if he gave his name. *E. W. Hardy.*

GROS MAROC GRAPE.—My experience of this variety is that in regard to flavour and quality, it is very often scarcely fit to eat. At the same time it has an excellent appearance, and is easy of cultivation. How a good judge of Grapes could place it before Muscat Hamburg and Madresfield Court, if these were properly finished, is beyond my comprehension. I was not at Edinburgh show, neither do I know any of the persons concerned, but Mr. Andrie, on p. 83, says Muscat Hamburg and Madresfield Court were shown "in splendid condition," and these being far more difficult to cultivate than is Gros Maroc, and moreover always good in flavour if well coloured, they certainly should have been placed first. Gros Maroc, Gros Colman, and Alnwick Seedling are good market Grapes, I have no doubt, but

unless specially stipulated in the schedule, Grapes possessing mere size of bunch or of berry, or a heavy bloom, ought not to win against others of better quality and flavour, provided they are well finished. Such Grapes as Mrs. Tince, Madresfield Court, and Muscat Hamburg are sometimes exhibited in very poor condition as regards colour, and I would not place any Grape first that is not properly coloured, for it would encourage faulty cultivation. *W. H. Diers, Belvoir Castle Gardens, Grantham.*

THE PARTNAGE OF ROSES.—I am much obliged to your correspondent, Mr. A. Piper, for his appreciative and interesting observations on p. 83 of the *Gardeners' Chronicle*. Before perusing them, I had already noticed the incidental slip of the pen in substitution of "Therese" for "Etienne" Level, in connection with the parentage of the Duke of Fife. That I was aware of its true parentage is evidenced by the fact that in previous articles contributed to other journals, I stated very clearly that Duke of Fife was a derivation from Etienne, not Therese Level, the latter of which I have never seen, though I believe it owed its origin to Jules Margottin. The great majority of Mr. Henry Bennet's Roses are vigorous in my garden; even Cleopatra and Princess of Wales have grown better than I anticipated. The Dean of Rochester writes to me as follows:—"Your song of praise in the *Gardeners' Chronicle* in honour of those who have 'obtained' new and beautiful roses, will have a loud and unanimous chorus from all rosarians; and will, I hope, encourage them to make experiments in hybridisation." *David R. Wilkinson.*

OUT OF DOOR PEACHES.—My thanks are due to you and Messrs. Warr and Wadds for replies sent to the writing *excess* mailing of Peach walls. I am glad that you both can write in praise of the former, and consider quite as good growth is made, and as good crops of fruit are secured, as when nailing is practised. It was not the desire to know how to wire a wall that prompted me to write about the subject, but if possible to hear what other growers whose Peach-wall happened to be wired, had to say about the crops they obtained. I had wired my wall before the above well-known gardeners' remarks were in print. It has an east aspect, and is 60 yards in length. *J. Mayne, Bolton, Devon.*

UNFAIR TRADING.—In these days of keen competition, when so many in the horticultural trade have the hardest work to make both ends meet, anything like unfair dealing should be stamped out, if possible, and the voice of the whole trade raised against a custom so largely prevailing by the salesmen of Covent Garden Market—a custom that is absolutely unfair, if not dishonest—I mean the custom of supplying gentlemen's gardeners with cut flowers at wholesale prices to be used in their employes' houses, with most likely a disregard to the gardeners' claim. It is just probable that the salesmen may be misled in the matter, and may be under the impression that they are sending to some florist shopkeeper or local tradesman; but surely they should do their best to ascertain the status of those they are supplying. Such a practice I know is largely carried on, and is most unjust to local growers and local shopkeepers, who when they buy in the market have to pay exactly the same price as My Lady's gardener. I know salesmen in Covent Garden market, who are in the habit of sending their wholesale priced lists regularly to private gardeners, and I, as one of the trade, protest against such unfairness, and I feel as one of the respectable portion of the Covent Garden trade will set their faces dead against such a custom. How, I ask, are the growers and florist-shopkeepers to live, if private gardeners are supplied at wholesale prices? Surely, if private people are supplied through the wholesale salesmen (as I do not think they should be) they ought, at least, to be charged the retail price, and the salesmen's published wholesale lists supplied to the trade only. *Local Florist.*

RORIDULA GORONIAS.—I have read the interesting note at p. 65 in the issue of the *Gardeners' Chronicle* for January 23, about the flowering of *Roridula goronias* at the Edinburgh Botanical Garden. May I point out to Mr. Harrow that this is not the first instance of this plant flowering under cultivation, as it flowered in the Glasnevin gardens last December, and a lantern-slide of the flowering specimen was exhibited by me on January 1. It is curious to note that in the Edinburgh plant the petals are stated to have been white, whereas in the Glasnevin plant they were pink. *E. W. Moore.*

WOOD-ASHES AS MANURE.—Mr. T. Fletcher, in his note (p. 82) referring to Mr. H. Smith, says: "He overlooks the most important point, viz., that the dust-ash of coal should be identical in composition and properties with the ash from wood." This, however, is by no means the case, for the ashes of wood contain a large proportion of potash, while coal-ashes contain scarcely any. Again, coal-ashes contain a large proportion of sulphuric acid, while wood-ashes contain but little. There are also other differences in composition and in mechanical texture between wood-ashes and coal-ashes. With reference to this point, let us ask, why are coal-ashes, which are derived from vegetable products, not identical with the ashes from wood? I have turned up much literature upon the question, but cannot find an answer, so I give my opinion for what it is worth. During the decomposition of wood, and other vegetable products which went to make up the coal, which may have occupied many thousands of years, before they were submerged, carbonized, and compressed, the rainfall and other atmospheric agencies separated the potash from the vegetable matter, which would thus become distributed and absorbed by the soil, and so lost to the coal products. Further, the nitrogen of vegetation is in the form of albuminoids; that is, nitrogen in combination with sulphur. In the course of the same decomposition previously referred to, the nitrogen would be given off as ammonia, while the sulphur would remain; this latter substance combining with the oxygen of the air and water, would produce the sulphuric acid of the coal. The difference in composition of the various samples of coal-ash referred to by Mr. Fletcher is doubtless due to the very different materials which made up the original coal-beds, and the degrees of oxidation to which they have been exposed. Thus we get soft, fluffy coal-ashes, and harsh clinker like ashes; the latter are the residue of the more gaseous kinds of coal. Coal-ashes are useful in altering the mechanical texture of clayey, tenacious soils, but they contain little plant-food. They are, however, good absorbents of liquid-manure, and when so treated they form valuable fertilisers. *J. J. Willis, Harpenden.*

THE DEODAR.—I wrote about the Deodar as commonly grown and familiar to everybody. Dr. Schnappach, of German forestry reputation, writing in the *Zeitschrift für Forstland und Jagdwesen* for December, on his inspection of Scotch forests says:—"The *Cedrus Deodara* thrives in the open in East Scotland, but is not so hardy in the more sheltered woods. It is only rarely by uncommonly severe winters," that is, "in the open," but in a forest a tree is more sheltered. *J. Simpson, Warrig.*

A PERFECT CLUSTER OF APPLES.—Permit me to thank you for giving the model cluster on p. 27. I have often wished—in making the most of, and securing as much freshness and originality as possible in arranging desserts—we could have more perfect clusters or sprays of Apples, Pears, Cherries, Plums, or other fruits to deal with. Of course, they can only be secured by forethought in thinning, and the sacrifice of a good many of the fruit buds for the succeeding years. But the few attempts made to make desserts more artistic through setting the fruit in clusters or branches were thoroughly successful. The Fairy, and other small high-coloured Apples, Crabs, occasional branches of Louise Bonne of Jersey, Marie Louise, and other Pears, branchlets of white and black Cherries, and the common Barberry, in fruit and foliage, will indicate how the light hand of art may enhance the charms of the dessert, without lessening its solid merits in any way. *D. T. F.*

SEED CATALOGUES.—An examination of the bulky catalogues issued by the leading seed houses in the present day, offers evidence of the rapid strides that have been made in the distribution of seeds as a business compared with what it was fifty years ago. There were no illustrations given away in those days, and very seldom were prices attached to the articles named, and no doubt this sometimes enabled the tradesman to charge according to the means of his customer. How different are things in the present day, when every buyer, who takes any small, would hardly think of purchasing seeds without getting some idea of their price. The originality and enterprise now displayed in the "get-up" of some of these annual publications is worth of more than passing remark; and an important change of recent date cannot fail to attract attention, namely, the extensive use of photography as a means of portraying vegetables, flowers, and fruits, thus enabling the

purchaser the better to make his choice. It is pleasing to observe that the heavy type and highly-coloured dubs, common a few years ago, are no longer so prominent, and the matter incorporated with the lists is more abundant and useful. It seems remarkable that there should still be a demand for many varieties of vegetables that were among the earliest to find their way into this country; and I have selected a few which are given in the following lists.—Switzer, 1727; R. North, 1758; R. Clarke, 1793; J. Mason, 1800; and J. Carter, 1812—all seedsmen in London—whilst some of them are found in the older herbals. Broad Windsor Beans, Sugar-loaf and Battersea Cabbage; Brown Dutch and Silesian Lettuce; white Spanish and Strasburg Onion; Long Red and Round Radish. From Carter's list of sixty years since I find Grange's White, Hampton Court, and Knight's Protecting Broccoli; Atkin's Matchless Nonpareil, Early York, Emperor Imperial, and Turnip-rooted Cabbage; Altrincham Carrot, Bath Cos, Paris Cos, Hammersmith, and Tennis-ball Lettuce; James Keeping, Deptford Onion; Matchless Marrow, and Victoria Marrow Peas, Olive-shaped Radish; White Dutch and Early Mousetail Turnip. *Scotsman.*

SOCIETIES.

NATIONAL CHRYSANTHEMUM.

THE NEWER INCURRED CHRYSANTHEMUMS.

Some differences of opinion have arisen among cultivators of the Chrysanthemum in regard to the classification of some of the newer incurred varieties, and especially those which originated in America, as these, they allege, are of the character of the new form, in not a few cases. That American raisers have crossed the old types of the incurred varieties with incurved Japanese there can be no doubt, and it would appear that cultivation in this country, for the first year or two at the least, brings out the marks of this sort of crossing, though it is found that when grown for a season in the States the new form is not a few cases more fully displayed; and the decisions of the Floral Committee of the National Chrysanthemum Society in respect of some of these varieties appeared to have run counter to that of the judges in a few instances at the recent Jubilee Exhibition. The Floral Committee of the Society made a recommendation to the General Committee that a Special Committee of Growers should be formed to take into consideration these doubtful varieties and classify them. A committee of fifteen persons was appointed, mainly consisting of trade growers and exhibitors, Mr. T. BEVAN, the Chairman of the Floral Committee, as President; and the report of this Committee was accepted by the General Committee of the N. C. S. on the 25th ult.

There will now be two types—the Incurved and Japanese Incurved, and all varieties which may be regarded as incurved, according to the standard of characteristics set forth in the Society's list of classes, will be recognised as incurved, and admissible in the competitive classes of incurved blooms. The following varieties are included in the class.—Duchess of Fife, Golden Nugget, Ideality, King of Orange, L'Anachyste, Leonard Payne, Miss Perfection, Miss Phyllis Fowler, Mrs. F. Hepper, Mr. J. Keam, Miss Louise D. Black, Mrs. James Elliot, Miss Dorothy Foster, Miss Violet Foster, Mrs. Aldrich, Mr. James Murray, Perle Dauphinoise, Percy Surman, Rosa Dula, Rosa Owen, Triomphe d'Éve, and The Egyptian. J. H. Bunchman, Olive Oeile, Lord Brooke, Robert Owen, and Sir Trevor Lawrence were classed as Incurved Japanese. In the case of Harold White, which was regarded as more correctly an incurved variety than Sir Trevor Lawrence, from which it is supposed to have sprung, the votes were equal, so its class remains undisturbed. Austin Cantell, to be found in some catalogues as an incurved, and Mont St. Eymard (Culver, 1895), were declared to be these varieties, as yet to be recognised. It may be added, that in every instance only those voted who had knowledge of the variety.

The foregoing report, or as much of it as it may seem desirable, will be published with the Annual Report, and be considered binding upon competitors at the Society's shows, and upon affiliated societies. If it should appear any of the varieties named in the foregoing report have been classed in the Society's Jubilee catalogue under different sections, this report shall be taken as determining the section of any variety named therein.

THE ROYAL SCOTTISH ARBORICULTURAL SOCIETY.

The annual meeting of this Society was held in Edinburgh on the 27th ult., when the President, Mr. R. C. M. St. J. FRASER, M.P., presided.

PROCEEDINGS IN FOREIGN AFFAIRS.

Mr. Dunn reported that the Council proposed that the exhibition of 1897 should be to Ireland about the middle of August. They expected to visit the estates of Lord Fitzwilliam and Lord Powerscourt in Wicklow, and a run might be made to Kilmaree. These provisional arrangements were approved of.

ADDRESS OF FORESTRY EDUCATION.

The Chairman next introduced Dr. William Schlich, Dr. Schlich, he said, had been a practical forester in Germany; he had occupied a responsible position in connection with the forests of India; he was at present head of the Cooper's Hill College; he had a management on his own account of a large area of wood-land upon the continent. He was not only a practical forester, but a forester and a practical forester was under exceptional obligation to him for his having come to address them upon a subject which greatly interested this Society.

Professor SCHLICH, who was cordially received, said his subject was Forestry Education, which he knew had occupied their attention a good deal in recent years. The first point which demanded attention was whether a case for better forestry education than that which our fathers had been able to give in this country had been made out. Forestry was an industry, and like all other industries, it was subject to the law of supply and demand. Until a recent time the demand was for arboriculturists and not for silviculturists. That demand was met by the corps of gentlemen who attended to arboriculture on the various estates of this country. To expect that these gentlemen should suddenly turn into experienced silviculturists to suit a demand which only lately had sprung up was hardly fair. Until recent times the economic question was, as far as the bulk of British woodlands was concerned, of minor importance, since these woodlands were of small extent, chiefly in the hands of a few, and, however, a change had come. Agriculture had fallen low, and the rent-roll of many proprietors had been seriously affected. The economic or financial importance of woodlands and the profitable utilisation of waste lands had come to the fore. The forest had ceased to be a mere domain for skilled arboriculturists, or wood managers, who were fully acquainted with the economic aspect of the industry. This was all very well, but forests which had hitherto been managed for other objects could not suddenly be converted into what might be called economic forests. This depended on the forest, and the man, and the demand for space of time, and it demanded the greatest skill of the silviculturist to effect it without loss to the proprietor. The thing could be done, but it required the training of wood managers on lines somewhat different from those hitherto followed in this country. To let them understand the difference between the two things, Professor Schlich went on to discuss the question why the timber now produced in Britain could not compete with that imported from abroad. They were aware that the great drawback which forestry labourers under in this country was the absence of a regular demand for home-grown timber. It was a comparatively recent date at which the State had begun to enter into contracts that home-grown timber would not be allowed to be used for constructive purposes. Why did such a condition of things exist? It was due to two causes, the inferiority of the quality of the home timber as compared with that imported from abroad, and the more haphazard manner in which the timber was brought into the market at irregular intervals and in fluctuating quantities. These drawbacks could only be remedied by a more systematic management of the forests. Under proper conditions, a regular market for home timber could be developed, and with better management he also showed that the cost of felling could also be, to a certain extent at least, neutralised.

What enabled gales to do mischief was the fact that often an open face was left to the wind. A great deal could be done to protect woods from the violence of gales by looking after the edge trees, and by planting along with shallow-rooted trees others with deeper roots for their protection. What the skill of the forester could do in that respect he instanced by a reference to the forests of Saxony, where the common spruce was the best-planting tree. There it yielded heavy crops, of which 80 per cent. were classed as timber, which was used for a variety of constructive purposes, and also for the manufacture of paper pulp, and only a very small amount of fuel. The trees were very little to be thrown by wind—in fact, no tree was more liable; but in Saxony the precautions were such that the damage done by gales was wonderfully small.

The next point discussed by Professor Schlich was natural versus artificial regeneration. Each method, he showed, had its advantages under certain circumstances, but on the whole he gave his influence on the side of artificial regeneration as being the best under an economic system of management of wood-lands.

The next subject of inquiry was whether there was a sufficiently large field open to them for extended action. An examination of the tables of imports and exports which were issued annually showed that the net import represented a sum of money by no means to be despised. Taking, for instance, the returns for the years 1890-91, it appeared that the annual average imports of timber, including wood pulp, were £2,000,000, representing a value of £3,000,000, of that sum £4,000,000 went to the colonies and £2,000,000 to foreign countries. By going back some years it would be seen that the average imports had increased by £2,000,000 a year during the last ten years. They might well ask us to resolve the question whether, if not the whole, at any rate a considerable portion of that timber could not be produced at home, and if so, what would be the effect on the return. He showed that as far as the climate is concerned about £1,000,000 worth of the timber imported could be grown at home, leaving £2,000,000 for the timber of species oak, mahogany, &c., which had no chance of thriving in these lands. Of the £17,000,000, no less than £11,500,000 repre-

anted coniferous trees, while the other 2½ millions were made up by oak and other hardwoods. And what were the Conifers? Baltic red Pine, which was their own Scots Fir; Baltic white Pine, which was the common Spruce; and American white pine, the bulk of which was Weymouth, a tree which, introduced into this country about 100 years ago, had been proved to be quite at home with them, yielding the best crops of timber that they could be desired for the purpose. To produce all the timber just mentioned would require at least five millions of acres. Were they available; a definite answer to this question could only be given after a detailed investigation of each county. But a general idea might be got by looking at the official agricultural returns. From the fact that there were in the three kingdoms waste land not used about 113 millions of acres, and mountains and heath lands used for rough grazing 12½ millions, giving a total of 263 million acres. Of these about one-half were in Scotland. No doubt a fair proportion of the waste lands could be used for afforestation, but the greater part of it was not for the purpose. Taking both kinds of land together, he did not hesitate to say that much more than five million acres were fit for afforestation. At the same time they must remember that, apart from rough grazing by the greater portion of the area was used for shooting—at any rate in part that was fit for shooting—and that shooting rents were high. Hence these lands could not be dealt with wholesale. In the north the income derived from shooting, including deer forests, was so considerable that the proprietors were very tardy and suspicious in respect of anything that might affect this important source of income. Still, by the aid of other proper arrangements, a considerable portion of the lands in question could be planted without interfering to an appreciable degree with shooting rents. In the case of deer forests, especially, he believed that afforestation of the lower portions of the area would be likely to increase their value in this respect, while gradually an increasing revenue from the planted areas would be secured.

Discussing the question, would it pay to plant? he said his personal experience as a practical wood manager led him to state that land which was capable of producing an average 15 tons of coniferous timber per acre a year could be profitably afforested. Such a result could be obtained on soil not more than 1½ per acre, or in the north, 2½ acres. In consideration, therefore, of the area already under forest in this country, and the very considerable additions to it which were possible, whereby a large sum of money might be kept in this country instead of going beyond the sea, a strong case had been made out in favour of forestry education. He might just mention that the forests of Schwarzenberg, which were 46,000 acres in extent and from 1,000 to 2,500 feet above sea level, yielded a net revenue of 2s. 1d. per acre, while the forest of Marienberg gave a net revenue of 27s. per acre. If they worked out the former sum they would find that it was not at all high a price that he did it, for they only got 15s. per cubic foot for the 240,000 cubic feet of timber these woods annually yielded.

Going on to consider the question who was to provide this improved forestry education, whereby a staff of wood managers would gradually be educated who were well versed in modern economic forest management, he said he had of late got much to say on this point. In his connection with Professor Schlich pointed out that the great bulk of the waste lands which might be planted belonged to private proprietors, and that the State had no great tracts of forest either belonging to it or under its control, as in France and Germany and India. These facts led him to think that they could not possibly be a sufficient basis for the State. The State's action, however, might reasonably be expected in the following directions:—(1) Assistance in the equipment of forest schools and training grounds; (2) management of, at any rate, a number of Crown forests on systematic economic principles; (3) advances at moderate interest to landed proprietors who were desirous of planting; (4) in some cases, for instance, where additional labour was wanted in congested districts, surplus areas might be acquired and put under forest. At the same time they could not close their eyes to the fact that as the proprietors of forests were the persons most interested in the systematic management of their woodlands, it was their duty to afford the means for the proper education of their agents. At least that was the view he took of it. Assuming that to be the case, why should they not be able to do as much as had been done, for instance in Bohemia and Moravia, where the proprietors supported three forestry schools at Weizsäcker, at Eutenberg, and at Leuberg, only the last mentioned of which received any annual grant from the State. It would not be too much to expect that the proprietors among them should find the means for the cost of forestry education in this country. Something, for instance, might be determined upon to take up the matter in real earnest, and to contribute 1d. per acre on their woodlands, say for ten years, that would be £300 a year. That would give the scheme a start, and bring that period some other arrangements might be made. Discussing further how the course of forestry education should be managed, he referred to the various estates which he had done at Cooper's Hill, and showed how that might be modified to suit the particular requirements of the country. The principle on which College was conducted was that the theoretical and practical teaching of forestry must go hand in hand. How this was to be accomplished he had never seen elsewhere. He found that to some extent they were several schemes running on parallel lines. There were a large number of foresters in Scotland who looked after the woods on estates of varying extent. Some proprietors

had only a few hundred acres, and others had thousands. The former employed a forester at a wooden, and when they paid hardly more than a skilled labourer; and even in the case of the larger properties the emoluments of the wood managers reached, as far as he was aware, a very moderate figure. Now, no young man in his senses would devote several years of his life, and a not inconsiderable sum of money, to the preparation for a position with a salary of £70 a year. But the proprietor might very well say—How am I to give him more? I have only small woodlands. According to his (Professor Schlich's) idea, they required two distinct classes of foresters—the working forester and the wood manager, or the forest expert. The former would do the "stump" or "plum" work, while the latter would lay down the method of treatment and supervise the execution of the work. Every proprietor would have one or a number of working foresters, according to the size of his woods, and a wood manager or a share of one. If his estate was of sufficient extent he would engage his own wood manager, and if he owned only a small area he would secure the occasional services of one. There were many examples where a land agent managed many estates; and there was no reason, as far as he could see, why the same should not be the case with wood managers. In that way they would secure the most efficient control over the woodlands, which they had made in educating themselves. Working foresters should be practically trained men, but they need not necessarily have attended a forest school unless they desired to work up to the position of wood managers.

Speaking of what was being done in Edinburgh, he said he could not help thinking that energy and money were likely to be wasted by running on too many lines at once. In his view, their chief energies should be directed to the education of the future wood manager, while working foresters would, for the present at any rate, do well to seek their training in well-managed forests. In his opinion, they would do better if, instead of the existing, they were to concentrate operations so as to make one definite scheme, forestry, and that scheme would be to perfect the education of their future wood managers. In other words, he should advocate (1) a centre of instruction, consisting of theoretical instruction in connection with a University or agricultural college where instruction in the auxiliary sciences is already provided; and (2) woodlands where the practical instruction could be imparted. As a basis for the former, he referred to Colind Aylesbury, and for the latter, he hinted that he did not approve of the joint stock scheme which was propounded, but hoped that the application of the Society to the Board of Agriculture for the purchase of a wooded estate to be used as a practical training ground would be successful. He mentioned in the question national interests of considerable magnitude were at stake, which he hoped would not be put back for another generation.

ASSOCIATION.

In the evening the annual dinner took place in the Royal Balfour Hotel, Dimes Street, and was attended by a company of about fifty gentlemen. Mr. Messrs. Ferguson, M.P., the President of the Society, occupied the chair; the compliments were Colonel Bailey, and Dr. Schlich gave the toast of the evening, "The Day of the Scotch Arboricultural Society." He drew special attention to the capital work which the Society had done during the last few years, and said that he had been quite struck by the excellence of the contributions to its *Transactions*. He was convinced that great good had come from the visit of the Society to Germany last year. In his opinion the gentlemen who had carried out that visit had done a very patriotic service. In some way Scottish arboriculturists had found that the method of treating forests in Scotland, from an economic point of view, was capable of improvement, and they had also found that continental foresters could learn a good deal from Scotland. The same, he thought, might be said of the best in Scotland to make forestry in this country profit by the experience gained on the Continent. There were some people who would like to make forestry a science pure and simple. That would not do. Forestry was an industry, and must remain so. It was an industry which dealt with a very big article, and that presented it being ever classed as anything but an industry. But nowadays they could bring an industry to a very high degree of perfection. But while they should never lose sight of the fact that forestry was an industry, they must recognise that a fully equipped forester must have a knowledge of every branch of science, for his was an industry of a very open science. Again, they must never lose sight of the financial aspect of the matter, for whatever object a proprietor might have in keeping up his woodlands, he always looked to have a return from them commensurate with the capital expended. *(Signed from the Scotsman.)*

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

The Annual Tea of this Association was held in the Abbey Hall, lent by Messrs. Serron & Sons, on Monday evening the 25th ult., when the newly-elected President, Mr. C. B. Stevens, presided.

FLORISTS' FLOWERS.

AURICULAS.

CULTIVATORS of this plant always wait with impatience for the arrival of February, as early in this month the overhauling of all the different sections of Auriculas takes place. It is now well known that the best trusses are produced on plants kept in an Auricula-house, from which frost is excluded. At the time of writing, I am placing the plants in a house, and quite close to the lights. It is prudent to remove the surface-soil in order that the neck of the plants may be examined, as it is at this part that the Auricula aphid is usually to be found. After cleansing the collar of the plant of these pests, re-surface with compost consisting of two parts loam, leaf-mould and decayed manure, one part each. Strong offshoots may be removed at this time. I recommend a top-dressing being afforded because it pleases the fanciers, but is not essential to the production of good blooms. The foliage should also be examined, and dust, green fly, or their excreta, should be removed with a soft brush. Green-fly itself may be removed by fumigation after the plants are placed in the Auricula-house.

I have just pricked out the earliest lot of seedlings. Some amateurs fail to obtain plants from show Auricula seed, especially that of the show varieties, which may be owing to the seed not being capable of retaining its vitality for many months, and it is advisable to sow the seed as soon as it is gathered; this is in July and August, or soon afterwards. The seed pots or pans should be placed in a frame on the north side of a wall or hedge, and the position chosen should be a very moist one, causing a growth of green in sn, through which the seedlings push freely. When possessed of two or three true leaves, prick them off a dozen or more together in a small 60 flower-pot. For the present all young Auriculas are best in the house. Alpine Auriculas varieties require the same kind of treatment as the show, if intended for cultivation in pots. *J. Douglas.*

CHRYSANTHEMS.

One of the most important matters in growing these plants for producing bloom fit for exhibition, is that as soon as the cuttings have rooted, no check of any kind should be given to growth, or stunting may occur. Some gardeners believe that great vigour at this stage is hurtful, and they endeavour to check growth for a time, which in my opinion is injurious, and it is not possible to cause the plants to grow too strongly at this stage, and the failure of plants may often be traced to lack of vigour.

When the plants are well rooted, and will bear exposure to the air without flagging, place them upon a shelf close to the glass in the house in which they were rooted, exposure to light affording strength, and more air is thus admitted to them than when placed on the side stages of a greenhouse. The young plants must be afforded water carefully, and never allowed to become dry.

Before a plant becomes root-bound, it should be repotted, and this is the time to take into consideration the size of pot in which they are to bloom. For most of the stronger-growing Japanese varieties pots of 10 inches diameter are suitable, the weaker-growing varieties going into pots 2 inches less. Pots of 9 inches diameter are suitable for most of the incurved varieties; a few of the weaker-growing ones, such as Lally Hardinge, do better in 8-inch pots. Those plants which are intended to reach a 9 inch pot ultimately should be placed into 3½-inch pots, and the next time into pots of 5 inches. When the last shift will be a 10-inch pot, 4½-inch ones may now be employed, and the next shift will be into a 6½ inch one. As the "cast" sizes vary, I prefer to give the sizes in inches, measuring the inner diameter. Always use clean pots, the roots clinging to the sides of dirty ones, and they are not easily detached. The soil for the first potting should consist of firy loam two parts, leaf-soil one part, and of spent Mushroom-bed materials one part, with a free admixture of sharp silver-sand for ordinary loam, and adding charcoal if it be heavy, the whole being passed through a coarse

sieve, rubbing the fibrous portions of the loam through it. To one bushel of this kind of compost add 1 lb. of Thomsson's Vine-manure. Crock the pots carefully, placing some of the rougher parts of the soil over these, and pot the plants firmly. It is important that the growth mode should be matured as it progresses, and firm potting helps this. If the soil is moist, as it should be when used, no water will be required for a day or two. After March the plants should not be allowed to smother lack of moisture at the roots, nor be kept constantly wet. Sometimes the leaves become pale in tint, showing that the amount of water in the soil is in excess of the needs of the plants, and less must be afforded, keeping the soil almost dry for a few days or a week. I have known cases of this kind of so stambrua a nature that recourse had to be taken to giving such plants weak doses of sulphate of iron, so as to restore the green colouring. After potting, place them again on the shelves, and keep them till the roots reach the sides of the pots; then place a tick to each, and remove to a cold frame or pit, standing them upon coal-ashes not far from the glass, keeping the frame rather close for a day or two, and afterwards admitting air more or less according to the state of the weather. On very fine days in March the lights may be taken off for a few hours. If green or black-fly appears in the points of the stem, dust the tips with tobacco-powder without delay. *E. Mitgane.*

Demand has been rather more active the last day or so, with only an improvement in prices, which rule as follows:—Dunbar Maincrops, 85s. to 95s. per ton; Dunbar Saxons, 70s. to 75s.; Lincoln Maincrops, 69s. to 75s.; do. Saxons, 69s. to 75s.; do. Giants, 59s. to 69s.; Blacklands, 35s. to 45s. John Bath.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fabr. for the period named; and this combined result is expressed in Day-degrees.—"Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

"The temperature continued much below the mean, the deficit ranging from 4° to the 'Channel Islands, to 6° in most other districts, and to 7° in 'England, E. and N.E.' The highest of the maxima, which were recorded on rather irregular dates, ranged from 48° in the 'Channel Islands, to 49° in 'England, N.E., and to 49° in 'England, E.' The lowest of the minima were registered either on the earlier or later days of the week, and ranged from 14° in 'Scotland, E.' 15° in 'Scotland, W., and 17° in 'Scotland, N., 'England, S.W. and Ireland, N., to 22° in 'England, E., and to 31° in the 'Channel Islands.'"

"The rainfall just stated the mean in 'England, N.W. and the Channel Islands,' and slightly exceeded it in 'Ireland, N.' In all other districts, however, the fall was less than the mean.

"The bright sunshine exceeded the mean in nearly all districts, but was rather deficient in 'Scotland, E. and the Channel Islands.' The percentage of the possible duration ranged from 40 in 'Ireland, S.', and 30 in 'England, S.' to 19 in 'England, N.W.,' 18 in 'Scotland, N.,' and to 11 in 'Scotland, E.'"

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

NARCISSUS VAN LION.—Would some of your readers kindly inform "Horti" if there are two varieties of the Double Van Lion Narcissus. There are, he says, Narcissus called Van Lion with shaggy trumpet flowers, the trumpet filled with petals; other times the flower is split up, and like a double N. incomparabilis. Are both of these Van Lions? if not, which is the true variety?

BOOKS: Constant Reader. Enquire of Mr. Upcott Gill, The Bacon Office, 170, Strand, London, W. We know of none in print.—G. M. P. In many, but not in all cases we have to buy the book, and then give it a gratis advertisement if we think it desirable in the interest of our readers. We should not be asked to do more. Publishers should advertise their wares like other people; the book you mention stands in a different position. It is issued in parts at 6s. or 6s., and there are several of them.

CHRYSANTHEMUMS: J. C. Very useful blooms in February, but we are unable to decipher the name you give them.

CINERARIA: J. McD. The appearance is due to the fusion of two or more flower-stalks, probably resulting from over-rapid growth.

DEVONIENSIS ROSE: U. M. To bring the Rose through the wall into an ordinary cold greenhouse would not result in your getting much, if any, bloom in the winter, the temperature being too low to induce vigorous growth. The variety would do well in an early Peach-house, and would flower abundantly, the pruning being done in early summer in time to get good long shoots on the plants well ripened the same year. The cultivation would have to be liberal.

FOWLS' MANURE: W. C. They might analyse this substance for you for a consideration at the Essex School of Agriculture, Chelmsford.

FRINGED CYCLAMENS: W. Klein. The address asked for is given in the note accompanying the illustrations, see p. 70 of our issue for January 30, 1897.

FRUIT-GROWING CENTRES IN THE SOUTH OF ENGLAND: C. M. J. Broxbourne, Sawbridgewort, Swaley, Brighton, and Worthing, the last two being well adapted for this kind of gardening under glass, by reason of the mild climate, and greater amount of sunshine enjoyed in the winter and spring months.

GARDENIA LEAVES SPOTTED: H. M. W. The dark spots on the under-surface of leaves of *Thibautiana* are superficial, and when removed the cuticle is intact. The material of which they are composed is amorphous, and resembles the exuviae of insects. Beyond this we have no data to determine. M. C. C.

GARDENS, &c.: E. M. The Physic Garden of the Society of Apothecaries is in the Queen's Road, Chelsea, near Battersea Bridge.

INARCHING THE GRAPE-VINE: *Novice*. Having a planted-out vine, and the vine to be inarched growing in a pot or alongside in the border, nothing

Obituary.

THOMAS BEDDARD.—We regret to announce the death of Mr. Beddard, head gardener at Stoneleigh Abbey, Kenilworth, which occurred at that place on Sunday, January 24, at the age of fifty-eight years. The deceased, who seemed to be in his usual health, died suddenly from some affection of the heart. He had held the post of head gardener to Lord Leigh for seventeen years, and was well known and respected throughout the county. The deceased gardener leaves a widow, but no children.

MARKETS.

COVENT GARDEN, FEBRUARY 4.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

No. of days above 42° since Jan. 3, 1897.							

The districts indicated by number in the first column are the following:— 0, Scotland, N. Principal; Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal; Greenhouses, &c.; Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending January 30, is furnished from the Meteorological Office:— The 7th, English N.W. and S. England, W. and 10, Ireland, S.; * Channel Islands.

The following summary record of the weather throughout the British Islands for the week ending January 30, is furnished from the Meteorological Office:— The 7th, English N.W. and S. England, W. and 10, Ireland, S.; * Channel Islands.

is easier than to inarch or join the two. In any case, it will be advisable to wait till leaf-growth has begun in both, so that bleeding may not hinder the union. It may be done by simply taking off with a knife a slice of equal size from each, bringing the cut surfaces accurately together, and binding them firmly. Clay or grafting-wax may be placed round the junction to prevent the ingress of water. Vine-shoots in a green state readily unite in the same manner, and this method affords a means of readily inarching vine-spurs of one variety with other varieties by means of Vines growing in pots, which may be for convenience sake suspended from the trellis.

LOBELIA PROPAGATION. *T. F.* Seed of Lobelia erinus specimens in variety is purchased as at the seed-dealers, and it comes fairly true to colour and habit; but the propagation of the different varieties from true stocks for planting in beds is advisable from cuttings only. There are in all gardens positions where excessiveness of the shade of colour and uniformity of habit are of not much consequence, and in those seedlings would answer; as also for culture in window-boxes, pots, as edgings to vases, &c. The pretty half-trailing Lobelia gracilis is an admirable plant for all of these purposes, and may be raised true from seed. Sow in gentle heat at the end of the present month, prick off early, the plant soon making a lot of roots; establish in heat, but remove afterwards to cooler quarters, or at least where more air can be afforded the plants. There are various methods of raising seedling Lobelias. Where many thousands are required, the seed is sown broadcast and thinly on the surface of a finely-sifted 6-inch layer of leaf-mould and loam, with a good deal of shrap sand in it, resting on a mild hotbed of tree-leaves and stable-litter, well prepared, and which has a steady heat of 80°; or seed may be sown in pots, pans, or cutting-boxes in the same kind of soil, placing these in a hotbed-frames. Care should be taken to prevent the drawing-up of the plants by affording air more or less to them from their first appearance above the soil, any neglect of this precaution, or letting the top-heat rise above 70°, will lead to wholesale damping off. This applies also to cuttings. The seed should not be covered, but pressed into the surface of the bed with a smooth piece of board, and a day or two after sowing watered with a very fine rose-can. Keep a sharp outlook for snails of all kinds, woodlice, &c. When a true tree or two have been made, prick off into other frames or pans next begin, and be carried out as fast as the seedlings become fit, which may occupy a fortnight altogether. Less heat is required by the plants at the top and bottom after April sets in, and towards the end of the month or early in May the plants should be sufficiently hardened to be safely placed in cold frames—at the least as regards the earliest-raised seedlings or cuttings. Some gardeners prick off both into small pots, say one in a long Tom, two in a large 60, or three or four in a small 48; others, again, scoop out small holes or narrow channels in fresh turves, placed on mild hot-beds, and filling these with fine mould, prick off the young plants at 2 to 3 inches apart.

MANURES. *Sibthorp.* We should imagine that you err in the term phosphate of potash. What is probably intended is a manure consisting of mineral or other phosphate of lime, and sulphate of potash, which along with sulphate of ammonia, insoluble and semi-dissolved bones, guano, &c., form the basis of many of the artificial soils. Probable cost 8s. per cwt.

HEALTHY BUDS ON VINES. *E. M.* As a further means of destroying and rooting out the pest, you should wheel away a couple inches crust of the border if it is an inside one; limewash the walls, and fill all crevices in the same and between the brickwork and the woodwork with hard mortar; and having washed the Vines in the manner described in your note, put on them some smoothing mixture of softsoap, clay, cow-dung, and soot. We are not acquainted with Mr. J. H. Richards' liquid insecticide, but it may be worth a trial.

NAMES OF PLANTS. *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*F. Swainth.* 1, *Asparagus plumosus*; 2, *A. plumosus nanus*; 3, *A. scandens deflexus*; *R. M.* 1, *Cyathea dealbata*; 2, *Davallia (Microlepia) platyphylla*; 3, *Cibotium Schiedei*; 4, *Drosera rotundifolia*; 5, *Drosera Friesii*; 6, *Maranta Veitchii*. *Onoid.* Two varieties of *Oncidium O'Brienianum*, *Leach.* f., an ally of

O. pubes.—*Dunroty.* Your *Cypripedium* is a form of *C. x Leeanum*, a class already overcrowded with varietal names.—*Gardener.* Your specimen appears to be *Ignea venusta*, but it usually carries more blooms in a cluster.—*G. Bartle.* *Climacanthus fragrans.*—*Southampton.* One appears to be *Phlomis buxifolia*, the other we do not recognise; neither has any flower to it.—*E. B.* As far as we can judge from the rather poor specimens, they are *Galanthus Elwsi*.

NOTICE TO QUIT. *Southport.* You are entitled to a month's notice or a month's payment, in the absence of any specific agreement. We have no record of special cases.

ORANGE TREES TO FLOWER IN SEPTEMBER. *Gardener.* If you can retard the plants, by keeping them cool, and by affording just sufficient water as will keep them in health; then, under the excitement of warmth and sunlight, and more water at the root, they may be got in full flower at the desired time. The season of flowering is naturally a long one. The flowers must be "wired" if used in bouquets.

POTATO SEEDS WITH ONLY ONE EYE, &c. *U. M.* The Bishop was right in recommending the removal of all the other "eyes," but few persons do it, they thinking the risk too great. As to staking and tying the Potato-stems, this is not likely to be adopted by many gardeners, although it, doubtless, has some advantages; these, however, would scarcely counterbalance the cost of the stakes, labour, &c. Wide planting would influence the weight of crop quite as well.

RENOVATING A BAOLY-SOWN LAWN: A. H. O.K. If it is very patchy, or has settled unevenly, it will be better to dig it over half a spit deep, when it is in a workable condition, and leave it untouched till the end of March or beginning of April, when it should be trodden evenly all over, and made level, either a dead or "hauling" level, as the case may be; finally raked over, taking off the rougher stones, &c., and sown on a dry, quiet day, taking care to sow the *Lolium perenne tenue* (Rye grass) first, and to hack it in with an iron rake. The following is a good mixture of grasses and Clovers for an acre of land.—*Lolium perenne tenue*, 20 lb.; *Cynosurus cristatus*, 5 lb.; *Festuca duriuscula*, 3 lb.; *F. ovina tenuifolia*, 2 lb.; *Poa nemoralis*, 2 lb.; *P. n. sempervirens*, 2 lb.; *P. trivialis*, 2 lb.; *Trifolium repens*, 6 lb.; *T. minus*, 2 lb. If the soil be rich and heavy, 1 lb. of *Festuca duriuscula* and 2 lb. of *Cynosurus* additional may be used. The sower should fasten a piece of board 2 feet by 1 foot to each foot. Rake in the seed after sowing with a wooden wide-toothed rake, and cross-roll the land well as a finish to it.

SELLING TWO TO THREE DOZEN ROSE BROOMS PER DAY. *F. T.* The blooms being cut and brought to market in a half opened state, should find ready purchasers among florists and market-gardeners. You should come up to the market and make enquiries for yourself concerning those things of which you are ignorant; such as the number of blooms demanded in a box, the best days on which to send, &c. No publication on marketing exists. Articles on the subject have doubtless appeared in these pages, but to find them would involve much expenditure of time which we can ill afford to give; and nothing but experience in the markets will supply the knowledge of which you stand in need.

SOCIETIES' ADDRESSES. *E. M.* You may obtain the addresses of the societies named by applying to Mr. W. Chubb, 1, Gt. Colonge Street, London, S.W.

SOWING SEEDS OF CONIFERS. *Conifer.* The land should be open—not shaded by timber trees, but it will be the better for the shelter of hedges, or of young plantations of evergreen trees. It should be manured, if poor, with decayed stable manure or cowyard-manure (the first for stiff soils, the latter for porous, gravelly loams), and dug two spits and the shovellings in depth, if it will bear it, that is, if the infertile subsoil be not brought up; as to do purpose. The seed of *Pinus*, *Abies*, and *Larch* are usually sown thinly broadcast in the spring, in 1-foot wide beds, and slightly covered with fine soil, sifted if possible from that in the alleys. The land should have been dug several months before, so as to let the soil settle, and should be levelled and trodden evenly all over, and then raked to a fine tilth, removing large stones and rubbish. The beds should be lined out, the outlines being cut

with a spade. We are unable to answer you as to the price per 40 yards run of seedling *Larch*, *Spruce*, &c.; but knowing the price per 100 of one-year-old stuff. We are sure that it would not be high.

SPARROWS. *U. M.* We can only advise you to shoot, trap, net, and take the nests, and not kill the different kinds of hawks. Do not, however, use poisoned grain.

STRAWBERRY. *Thornton Heath.* The plant is a genus belonging to the natural order Rosaceæ, distinguished by its ten-cleft calyx, five petals, and its carpels or pips embedded in a fleshy receptacle which we call its fruit.

THE COST OF KEEPING NURSERY-LAND CLEAN AND FREE FROM WEEDS. *Conifer.* Unless very much infested with weeds, one man ought to be able to keep 3 acres in a clean condition, except in wet summers; the price per acre will, therefore, depend on the average labourer's wages of the district in which the nursery lies.

TOMATO SOIL. *C. Boyle Woolley.* There would be nothing to fear this year by using the soil as it is, only adding a rich mulch if the plants seemed to need such later on.

TRAPS FOR WOODLICE. *B. B.* The older commonly-employed contrivances for catching woodlice consist of pots, drain-pipes, &c., filled with soft hay, slates laid on the floor, but not quite touching it, under which they will hide in the presence of daylight or artificial light, and are then readily destroyed. The hollowed-out half of a Potato you mention is a good one, but it is not sufficiently wholesale in its action.

TWELVE AZALEAS. *W. White.* Apollon, Bernhard Andreas, Borsig, Deutsche Perle, Etendant do Fleurde, Iveryana, Le Flambeau, punctulata, Roi des Belges, Roi Leopold, President Oswald de Kerchove, and Sigismund Rucker. The price for nice plants in 32's is about 24s. per dozen.

VIOLETS. *U. M.* Much will depend on the management of the plants previous to, and after putting them into the frames. The Neapolitan is the latest to flower of the three varieties you mention.

WIRING A PEACH WALL. *Norfolk.* You would be enabled, in spite of the buttresses occurring at 12 feet intervals, to wire the wall as closely as possible, if you place the wires vertically, which is the better method, as the lengths being only as long as the wall is high, saggy but little, and they can be fixed at the top and bottom with eyes or studs only slightly stronger than those used internally. Wire when run horizontally requires to be very stout to enable it to be strained by means of *raisinisseurs*. The size of wire to be used for vertical work need not be stronger than one-tenth of an inch diameter, if of plain iron.

CONTINUED LARGE INCREASE in the CIRCULATION OF THE "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has satisfaction in announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

Increased to the extent of more than 90 per cent., and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, FEBRUARY 13, 1897.

AMERICAN TREES.*

THE issue of the tenth volume of this remarkable book reminds us that it is approaching completion—already the Conifers have been reached. Another volume will, we presume, include the remainder of the order, or nearly so, and then there will be indices and tables to finish up with. We have nothing to add to the eulogium already passed on the general features of this superb book. It must, in the future, be the standard book of reference in all matters relating to the trees and shrubs of America.

It seems to us, nevertheless, on this side of the Atlantic, unfortunate that the author should have adopted the Neo-American, or, perhaps, we might call it the Kuntzean system of nomenclature; but if that is really to be the system of the future in the States, we can hardly blame the author for wishing that his book should be in harmony with the circumstances. In the present volume there is no change in nomenclature of any great importance, except that *Torreya* is made to give place to *Tumion* on the authority of Rafinesque. This name, *Tumion*, we may say, is of later date than *Torreya*, and is entirely passed over in the *Index Kewensis*, as also in Baillon's and in Eichler's recent monographs of the Conifers. As the *Index* and the synonymy sufficiently enlighten the reader, this revival of Rafinesque's name is not, after all, a matter of serious consequence.

The present volume is specially interesting to British horticulturists, as containing a full account, with beautiful illustrations, of the species of *Yucca*. Of these no fewer than eight are described in this volume. Whilst the technical descriptions are most important for the sake of the record, the notes and incidental information are of great interest to the general reader. In this way so vast an amount of miscellaneous information is got together that the book becomes a veritable encyclopædia. We extract, by way of illustration, a few miscellaneous paragraphs relating to those plants:—

Yucca glifera, the largest of the *Yuccas* now known, is a tree often 50 feet in height, with a trunk frequently 20 feet tall, and 5 feet in diameter, and many wide-spreading branches, and is distinguishable from all other species by its pendulous panicles of flowers and fruit, which are often 6 feet in length. It forms open forests of great extent on the plains, which rise from the lower Rio Grande to the Sierra Madre, and ranges southward to San Luis Potosi. Introduced nearly forty years ago into the gardens of Europe, it is also occasionally cultivated in some of the Texan towns along the Rio Grande, and in Northern Mexico, where it is often used in the neighbourhood of Monterey and Saltillo to form stockades.

* *The Trees of North America*, &c., by C. S. Sargent, Director of the Arnold Arboretum of Harvard University. . . . Vol. 5., Libellæ—Conifere. (First issued New York: Houghton, Mifflin & Co.)

Yucca filamentosa.—This stonless and very variable species inhabits sandy barren soil and abandoned fields in the neighbourhood of the coast, from southern Maryland, southward to Florida, and westward along the southern borders of the Gulf States of Louisiana. It is the best known of all the *Yuccas* in northern gardens, which it enlivens in midsummer with its great panicles of large ivory-white flowers. The tough leaves of this species are twisted and used in the southern States for hanging hams and for other domestic purposes. Attempts have been made to utilise their fibre commercially; but, though it is exceedingly strong and cheaply produced, the shortness of *Yucca*-fibre lessens its value, and it has not yet been successfully introduced into commerce.

Yucca arborescens.—About twenty-five years ago at Ravenna, in the Solidad Pass, just south of the Mohave Desert in California, a company of English capitalists established a mill for the manufacture of the wool of *Yucca arborescens* into paper-pulp. A quantity of paper was made from the pulp, and it is said that several editions of the *London Telegraph* were printed upon it; but the high cost of manufacture more than consumed the profits of the enterprise, and it was soon abandoned. . . . First noticed by Frémont in 1844 on the Mohave Desert." The Joshua-tree, as it was called by the Mormons of Southern Utah, was not described until many years later. Railroads now cross the Mohave Desert, and from the window of his car the traveller can see the forests of *Yucca arborescens* stretching indefinitely into the hazy distance, unlike any other forest on the continent, and without a rival in singularity and weirdness."

Following the *Yuccas* come the *Palms*, of which no fewer than seven or eight species are enumerated, five from Florida and other southern States, and three from California and Mexico. After the *Palms* come the *Conifers*, which are numerous on both sides of the continent, some even extending into the sub-tropical regions. In the present instalment we have the *Taxaceæ*, the *Junipers* comprising nine species; the *Cypresses*, of which there are seven; the *Thuayas*, of which two are mentioned; *Libocedrus* being represented by one species.

As to the *Thuayas*, there are some curious facts relating to their history which may be here alluded to. There is *Thuja occidentalis*, a native of the Atlantic States, and which has afforded a large number of varieties. These are well known in our gardens as forms of the American *Arbor-vitæ*. There is no doubt at all about this species. On the Pacific side, northwards, is another species which again is easily recognisable—it is the one called by Nuttall, in 1834, *T. gigantea*, but which has also been called in gardens T. *Lobbi*, T. *Craigiana*, and T. *Menziesii*, three names that should be at once abandoned. This is a splendid fast-growing species, bearing clipping and pruning, and which bids fair to form a useful timber tree.

So far, all is plain-sailing—the difficulty begins when *T. plicata* comes in. The first-published mention of the name *plicata* is in James Donn's *Hortus Canab.*, ed. 1 (1807). Incidentally, it may be mentioned that by almost all subsequent writers the name is written *Don*, and the sixth edition (1811) is quoted when the fourth is the one in which the plant is first mentioned. Successive botanists have not verified their references, but have quoted one from the other. But this, in this instance, is a matter of little moment. More important for us is it to note that *plicata* is a *nomen nudum*—a name with no description attached, and which therefore should have been passed over. It was not ignored, probably,

to which, as well as to all the country, so far as we could see, the *Yuccas* trees gave a strange and singular character. (*Esment, Rep. 257*)

because Donn adds the information that the species was discovered by Née at Nootka Sound, and introduced in 1796. This information led to the inquiry who Née was, and where his specimen of *Thuja* might be found. The following extract satisfies the first question:—

"Luis Née, a Frenchman, naturalised in Spain, and one of the botanists who accompanied Malaspina on his voyage round the world. He was a most indefatigable collector, and was endowed with considerable scientific ability. On the authority of Coluccia, Née was the first to make the interesting discovery of the existence of *Rhododendron ponticum* in the Iberian peninsula. Malaspina's voyage was made during the years 1789 to 1794; and when Née landed at Cadiz he had made a collection of dried plants estimated at 10,000 species, including 4000 new to science. Like many other fine collections made by Spanish naturalists, it has been permitted to be at Madrid unused. There were also upwards of 300 drawings by various artists." *Humbly, "Biogeo. Centr. Americana,"* iv. p. 119. (See *Coluccia, "La Botánica y los Botánicos de la Península Hispánico-Istulana,"* p. 183.)

The answer to the second question was suggested by a reference to Lambert's *Pinus*, the 8vo edition, dated 1832. Lambert mentions (p. 127, n. 61) *Thuja plicata*, or *Née's Arbor-vitæ*, describes it, and quotes Donn's name. The localities given are New Spain (Mexico), where it is alleged to have been collected by Née, and the north-western coast of America, at Nootka Sound, where it was found by Menzies. "The specimens of this species collected in the expedition under Malaspina by Don Luis Née, although marked from New Spain, are most likely from Nootka Sound, where the tree was observed by M. Menzies, to whom it was probably we are also indebted for its first introduction to our collections, as there does not appear to be any marked difference between the wild and the cultivated samples, unless that the branches of the latter are broader and more compressed." Lambert, *l.c.*

Furnished with these clues, an examination of the herbarium at the British Museum was the next step, and there we found two specimens from Menzies, and called T. *Menziesii*, with a MS. note of Salisbury's, and an imperfect specimen labelled "*Thuja ex Nov. Hispan. Née, det T. plicata, nob.*" Cavanilles' name being written on the back, as if Cavanilles was the "*nobis*." These specimens, we think, belong, without doubt, to what we now call *T. gigantea*. If this be so, *T. plicata* is the earlier name, and we suppose some of the nomenclature purists would forthwith adopt it. These circumstances induced us once more to investigate the *T. plicata* of gardens, and we are indebted to the authorities at Kew, Cambridge, to Mr. A. D. Webster, and to other friends, for specimens of *T. plicata* as now cultivated, and which undoubtedly have nothing to do with the original *plicata* or modern *gigantea*, but which equally certainly are varieties of *T. occidentalis*.

One more question arises, and that is, whether the "*plicata*" of British gardens at the beginning of the century was the same as that still in cultivation; but this point we cannot determine.

Lastly, in order to bring our story down to the present time, we append what Professor Sargent says of the garden-plant now known as *T. plicata*:—

"A small compact *Thuja*, regular in outline, and said to have been discovered by Menzies on Vancouver's Island in 1796, as well as several forms raised in gardens, has long been cultivated in Europe

under the name of *Thuja plicata*. (D. Don, *Cat. Hort. Cantab.*, ed. 6, 249 [1811]; Lambert, *Parus*, ii, 19; Spach, *Hist. Vég.*, ix, 342; Endlicher, *Syn. Conf.*, 51; Carrière, *Traité Conf.*, 192; Henkel and Hochstetter, *Syn. Natlth.*, 277; Gordon, *Pinetum*, ed. 2, 496; Parlatore, *De Candelis Prodr.*, xvi, pt. ii., 457; Beissner, *Handb. Natlth.*, 44). There is great uncertainty in regard to the true character of the plant originally described by Don, but most of the individuals now cultivated under this name are forms of *Thuja occidentalis*, although *Thuja gaitanea* is also occasionally cultivated as *Thuja plicata*. No tree resembling the *Thuja plicata* of gardens has been found in North-western America, and this plant, like most of its varieties, is best considered a garden form referable to *Thuja occidentalis* rather than to *Thuja gaitanea*.*

Sequoia is represented by the two well-known species, the *Wellingtonia* and the *Redwood*; the deciduous *Cypress*, *Taxodium distichum*, being the last in the volume. Of all these, in addition to the letter-press, there are excellent illustrations giving the details that are essential to botanists, but which the ordinary artist omits or slurs over. This enumeration, bare though it be, bears out our statement, that this volume is of special interest to horticulturists. We look forward eagerly to the remaining volumes, comprising the history of the American Pines, Firs, Spruces, and Hemlocks.

INFLUENCE OF FRUIT-BEARING ON THE MECHANICAL TISSUE IN FRUIT-TREES.

THE December number of the *Annals of Botany* contains a paper by Mr. Adrian J. Pieters on "The Influence of Fruit-bearing on the Development of Mechanical Tissue in some Fruit-trees." The author mentions, among other authorities on this subject, Sauerer, who published more than one paper relating to it. Mr. Pieters says that:—"The inference drawn from Sauerer's work is that cultivation, and more directly fruit-bearing, may become injurious to a tree by reason of the greater development of cortex, and the proportionally smaller amount of xylem produced in the fruit-bearing shoot, which renders it weaker mechanically, and more liable to injury by frost.

I shall present here a study of the effect of fruit-bearing on the permanent mechanical tissue of the tree, in order to show the influence upon any tissue-system of the strain to which a tree is subjected in the production of fruit and seeds."

Four species, namely, Apple, Pear, Peach, and Plum are reported upon by Mr. Pieters, whose observations are concluded in the following summary:—"The study of these four species seems to warrant the following conclusions, in answer to the questions proposed at the beginning of this paper—

1. The one-year-old fruit-bearing shoots of the Apple and the Pear have less wood in proportion to their diameter than does the vegetative shoot of the same age. This is due, in the Apple, largely to an increase in the cortex, and in the Pear solely to a great increase in the cortex and the pith of the fruit-bearing shoot. It does not, however, appear, from the structure of the shoot, that the fruit-bearing shoot is weaker than the vegetative. The former is well supplied with supplementary mechanical tissue, which is distributed at those points where it is most needed, and thus gives it an increase of strength for the fruit-bearing year, which fully makes up for the difference in xylem development.

2. In the Peach the fruit-bearing shoot has more wood than the vegetative shoot, and the walls of the wood-cells are as thick in the former as in the latter.

* By "mechanical tissue" is meant all those collections of cells having thick and lignified walls, and serving to give strength and firmness to the shoot. Since the wood-cylinder is the principal collection of such cells, and is the only one capable of accurate measurement, most attention will be given to it, with incidental reference to supplementary mechanical cells, when these are of importance.

3. In general it may be said that the effect of fruit-bearing upon the tissues is local. In the Apple and Pear it is perceptible throughout the one-year-old shoot; in the Plum and Peach it is confined to a small area in the immediate neighbourhood of the fruit-stalk.

4. The local effect of fruit-bearing tends to an increase of cells, with a decrease in the thickness and lignification of the walls of the wood cells. The cortex is especially enlarged, giving rise in the Apple and Pear to the swollen condition of the fruit-bearing shoot.

5. In all cases the increase in growth is greatest on the side near to the fruit-stalk, although the wood in the Apple and Pear is best developed on the side of the lateral vegetative bud.

6. The local effect of fruit-bearing on the wood-cylinder disappears with time. The study of Apple-shoots that had borne fruit during their first year showed that in the two or four years following there had been a rapid increase of wood, especially on the side of the fruit-scar. This side was weakest at the end of the first year. These shoots at the end of three and five years had a better xylem-development than shoots of the same age that had never borne fruit.

7. Fruit-bearing has a temporary local effect upon the lignification of the walls of wood-cells. It prevents their lignification wholly or in part according to their distance from the fruit-stalk. The lignification of other cell-walls is promoted by fruit-bearing. In the fruit-stalk the greatest part of the tissue has become lignified, and in the upper part of the Apple—and Pear—shoot there is an abundance of well-lignified sclerenchyma and hard bast, which is either not found in the vegetative shoot or only sparingly so."

ORCHID NOTES AND GLEANINGS.

A GROUP OF CUT BLOOMS.

MR. J. P. SHAW STOREY of Bursledon obliges us with a photograph, showing, as arranged in a group of specimen-glasses, *Lycaste Skinneri* alba (4), *Laelia anceps* alba, *L. a. Sanderiana*, &c. The photograph is effective, but the arrangement would have been better had some sprays of *Asparagus* been intermixed.

CYPRIPEDIUM INSIGNE, SPOTTED VARIETY.

Flowers of a remarkably pretty and distinct variety of *Cypripedium insigne* is sent by Mr. W. Bolton, a cultivator of Orchids, and a florist at Wilderspool, Warrington. We may assume that when the plant becomes older and more vigorous, the flowers will doubtless improve, as those sent indicate a plant which is as yet not thoroughly established, the lower sepals, and tip of the upper sepals being imperfect. The flower lacks the usual brown tinting visible above the yellow colour of the petals, and except in a very slight degree, that also over the face of the lip; and the colouring consists in well-defined purplish-brown spotting on a yellow ground-colour, the distinct spotting extending to the inside of the pouch. The petals are broader than usual, and consequently display the peculiar spotting prominently; and the tip of the upper sepal is white.

DENDROBIUM JOHANNIS.

Originally discovered on York Peninsula, North East Australia, by the late John Gould Veitch, after whom it was named by Professor Reichenbach, and described in the *Gardeners' Chronicle* in 1865. This singular species has occasionally appeared in gardens, but it has never been plentiful. The plant resembles in habit, a stout, dwarf D. bigibbum, but it is readily distinguished by the fleshy, ligulate leaves of other species, although occasionally in a dry state its inflorescence has been taken for that of *D. undulatum*, a species to which the fresh flowers bear but a slight resemblance. The ascending flower-spikes bear numerous flowers, having narrow twisted sepals and petals; in colour, greenish tinged with brown, and a yellow lip, the side-lobes of which are purple-shaded. It is not a plant for anyone to grow in quantity, but

as a species it is acceptable. A specimen is sent by Mr. W. Bolton, florist, Wilderspool, Warrington, who also sends a strong twin-flowered *Sophranitis graciliora*.

RUBECKIA NEUMANNI OR NEWMANNI.

LAST autumn there was an inquiry about this plant in your columns, by the Rev. C. Wolley Dod, which I intended to have answered before now, but I was from home at the time the inquiry appeared, and forgot the matter on returning to work. To-day the subject was revived in my mind by finding a specimen so named in the herbarium of the late Mr. W. H. Gower. These two varieties are garden names for *R. speciosa* of Wenderoth, which Dr. Asa Gray keeps up as a species, and fully describes, with synonymus in his latest monograph of the North American Compositae. Whether *R. speciosa* is distinct in any broad sense from *R. fulgida* of Linnaeus, may be doubted, but, at any rate, for garden purposes it is the finest of the group to which it belongs, which includes *R. hirta*, L., with its many varieties. We have at Kew a specimen labelled *Newmanni* from Cobham Lodge, dried by the late Dr. Forbes Young in 1832, so that the name must have been floating about for more than sixty years. Another specimen, labelled *R. aspera*, from the same collection, is identical, so that it is probable the *R. aspera* of Desfontaine's tableau of the plants of the Paris garden, published in 1811; but as no description is given, there are no means of verifying this supposition. The name *speciosa* was published in an *Index Seminum* of the Marburg Garden, and dates back to 1828. *J. G. Baker*.

CRATEGUS.

(Continued from p. 88.)

C. Oreganatha (The common Hawthorn, Quick, May, &c.).—This species is made up of two sub-species or varieties, viz., monogyna and oxycanthoides; these, although connected by intermediate forms, are distinct enough to be treated separately. Both have their attendant group of varieties.

Monogyna.—This comprises the greater bulk of the named varieties, and is to be distinguished by the flowers having only one style, and the fruits one seed. The leaves are larger than in the other group, somewhat wedge-shaped, and more or less deeply cut. Among the numerous forms, the following are the most noteworthy: *Aurea*, a very desirable plant, whose fruits are roundish and of a clear golden-yellow; this year they have been particularly abundant, giving the tree a most bright as well as distinct appearance, for there is no other Thorn with fruits of just the same colour. *Eriocarpa* has small woolly fruits. *Flexuosa* (or *tortuosa*) is a curiosity, its branches being twisted and contorted. *Horrida* is a form of dwarf habit with frequently stunted branches which are very formidably armed with cushions of spines. *Præcox* is the Glastonbury Thorn, famous for the legend connected with its early flowering; unless hard weather sets in prematurely, it is generally to be seen with a few flowers open about Christmas or New Year's Day. *Stricta* is in habit almost as erect and fastigate as the Lombardy Poplar. Besides these there are many more whose names sufficiently denote their distinctive character, such as *pendula*, *laciniata*, *foliis argenteis*, *salisburifolia*, *ramulis aureis*, &c., &c.

Oxycanthoides.—This, the type of the second and smaller group, differs from *monogyna* by its flowers having usually more than one style, and by the fruits being one or two seeded. In foliage, too, it differs in its smaller leaves, which are frequently almost undivided, or with three shallow lobes towards the apex. This group comprises the valuable double flowering Thorns of which Paul's Double Scarlet is one of the best known. The botanical names are merely descriptive of the different colours and double nesses of the flowers (here *plena*, *alba*, &c.); it is not necessary to transcribe them.

C. pinnatifida.—A Chinese species, with long-stalked, pinnatifid or deeply-lobed leaves, the lobing being deepest at the base of the leaf; the blade is about 3 inches long, an 1 as much in width, of a bright shining green, and glabrous on both surfaces, with the margins toothed. The flowers are white, and about three quarters of an inch across; the dark, shining red fruits about the same in diameter.

Var. major.—This is a fine plant, and one of the most distinct and striking of the Old World Thorus. The foliage is more abundant than that of the ordinary *C. pinnatifida*, also of a deeper green, and much larger size. I have seen leaves during the past

C. Pycnantha.—This well-known evergreen shrub is a native of South Europe, and has been in cultivation in Britain since 1623. Although perfectly hardy in the open, its full beauty as a fruiting shrub is seen only when it is grown against a wall, or in some sheltered sunny corner where the wood can be well ripened. There is now in the Terrace Gardens at Richmond a small specimen, planted among dwarf evergreens on a sloping bank near a wall, which is a most beautiful object. The horizontal branches are loaded with pendent clusters of brilliant scarlet fruits. The leaves are $\frac{1}{2}$ to $1\frac{1}{2}$ inch long, ovate-lanceolate, crenate and glabrous. Each axillary branch ends in a

species from the Orient, allied to *C. Azarolus, orientalis*, &c. It has deeply three or five-lobed leaves, which are 2 inches long, and glabrous on both surfaces; the lobes are cut almost longitudinally, and are entire, or only faintly toothed. The wood is dark-coloured, and armed with a few short, stout spines, not often more than half an inch long. The fragrant, pure white flowers appear in May and June. The fruits are ripe in September, globose, yellowish-red, and three-quarters of an inch in thickness; they are glabrous, and the calyx-lobes at the top are short and triangular. The species is wild on Mount Sinai, hence Boissier's name. Lindley figured it as *C. marocana* in the *Botanical Register*, t. 1855. W. J. Bean.

(To be continued.)

FIG. 28.—IRIS BAKERIANA.

(See Report of Royal Horticultural Society, p. 114, col. 3.)

summer 6 inches long. The lobing is not so deep, and the leaf is thicker in substance; the midrib and veins, as well as the young wood, are of a darker, redder colour. The fruit is rounded, oblong, and resembles that of the North American *C. punctata*, being frequently an inch across, of a dark lustrous red, and marked with scattered dots; the calyx lobes are short and cuspidate. It has been known as *C. tartarica*, Messrs. Veitch having introduced it from Tartary. They obtained a First-class Certificate for it at one of the Royal Horticultural Society's meetings in October, 1886; it had, however, been in cultivation long previously. There are old trees, 15 ft. high, in the Kew Arboretum. Several other names under which this tree has been distributed are given above.

stiff, sharp spine. When grown in the open it makes a handsome bush of close yet graceful habit. It will grow 8 feet high there, but much higher on a wall.

Var. latanides is now much grown. It is of stronger and more open habit, and the fruits are orange-coloured.

C. sinuata.—A Siberian species, figured as *C. spinosissima* in Loddiges' *Botanical Cabinet*, t. 1100. It has sharp, moderately stout spines, $1\frac{1}{2}$ inch long, and dark-coloured winter-buds. The leaf is broadly ovate in the main, but deeply lobed and serrated, and from 2 to 3 inches long. The flowers, nearly 1 inch across, are white, with a faint flush of pink. The fruit is about the size and shape of the common haw, but ripens late.

C. sinuata (syn. *C. marocana*).—A handsome

VARIORUM.

THE OLDEST PEAR-TREE.

We read in the *Illustrated Garden Zeilung* for January that King John's Pear-tree at Toulou was overturned by a hurricane in the last week in November, 1896. The tree was supposed to be 600 years old, and the hole had a circumference of 10 feet. M. Chabaud, upon whose ground the tree had stood, has enquired of all the botanical garden authorities in Europe if trees of similar age and dimensions are known to exist elsewhere.

IMPORTANCE OF PHOSPHORIC ACID IN SOILS.

THE element phosphoric acid is universally acknowledged to be one of the most important ingredients in manures; and after nitrogen, and in some instances potash, is the one substance of which ordinary soils stand in greatest need, and become the soonest exhausted.

Professor M. Risler, President of the National Agricultural Society of France, recently called attention to this subject, and stated that an average harvest of Wheat required for its development from 20 to 25 lb. of phosphoric acid per acre; while an average crop of Potatoes required from 25 to 30 lb. of phosphoric acid per acre. A forest of Pine-trees requires 4.75 lb. of phosphoric acid per acre per annum, and yet the greatest part of this phosphoric acid, namely, 3.68 lb., is assimilated by the Pine-needles and twigs that fall to the ground, and there decay, restoring to the soil by their decomposition those elements which they had originally taken from it. The hard wood of the Pine tree absorbs scarcely more than 1 lb. of phosphoric acid per acre per annum. It has been found, however, that the quantity of phosphoric acid present in the soil has a considerable influence upon the vigour and healthy growth of Pine-trees.

In some investigations by Prof. Schultz at Bavaria, the results showed that the best class of soils for the growth of Pine-trees contained 0.569 per thousand of phosphoric acid. In the second class of soils adapted for the culture of Pines, 0.501 per thousand of this element was found. In the third class, 0.388; in the fourth class, 0.299; and in the fifth class, or most inferior description of soil adapted to the growth of Pines, only 0.236 per thousand of phosphoric acid was found in the mould.

Spruce Pines and Oaks abstract from the soil by their growth more phosphoric acid than do Pine-trees, in fact, almost twice as much; but even this is infinitely less than most cultivated plants of the garden require for their perfect development. This is explained by the fact, that forest-trees possess exceedingly long roots, which descend deeply into the earth, and thus are enabled to bring up phosphoric acid and other mineral matters according to their requirements. This sub-soil source of plant-food is not got at able by most plants, and helps to explain the enrichment of surface soils under forest-trees. The falling leaves and vegetable debris go to make up the humus of forest-moulds.

It may be said that phosphoric acid is one of the fertilising elements in manures that tend most strongly to accumulate in the seeds of plants. It passes rapidly from the leaves and stems into or towards the fruit, through all the stages of growth, from first to last. *J. J. Ellis, Harpenden.*

EDINBURGH BOTANIC GARDEN NOTES.

LELIA SUPERBENS.—This strong-growing Guatemalan species is at the present time flowering in the Orchid-house. It has a great resemblance to *Schomburgkias* in habit, and in the production of the long scape with the flowers arranged at the apex. The spindle-shaped pseudo-bulbs are about 18 inches in length, and the plant in these gardens has only eleven flowers, but from ten to twenty are said to be borne by the plant in a state of Nature. The flowers are coloured rosy-mauve, with a lip of purple and gold. It is said to have been collected where bear-foots prevail. A good heat is required to properly cultivate this plant during its period of growth. The Royal Horticultural Society are credited with having first introduced this species in 1842.

PLEUROTHALLIS SCAPATA.

Although ranking among Orchid curiosities, yet this plant is well worthy of a place in our collections, by reason of its free-flowering. The stems are erect, and bear a single leaf, from the base of which arises a raceme of six to ten flowers. The dorsal sepal is 2 inches or more in length, and narrowed to a pointed tail, and the sepals and petals possess this spidery appearance. They are greenish-yellow in colour. The figure in the *Botanical Magazine*, t. 7421, was drawn from a specimen received from Mr. Moore, of Glaesvick, who grows the plant in a cool-house. The Edinburgh plant succeeds in the Cattleya-house, and flowers from every growth; one growth, indeed, throwing up a second spike.

MACKAYA BELLA.

This lovely Cape shrub is always attained when well flowered, but unfortunately it is not often met with in fine condition, which is probably the reason that gardeners consider it to be a shy bloomer. A plant has been in flower in the succulent-house for the past month, where it occupies a position in the central bed among Agaves and other similar plants. Planted in the early part of 1896 from a 6-inch pot, the stems grew rapidly until they reached the height of about 7 feet. Several of these were cut out owing to lack of space, three being left. The side branches from these stems form a diameter of 4 feet. The foliage produced is large, and of a dark green colour, and from every small branch a pendulous raceme springs, terminating its growth, and some of the strongest of these inflorescences carry from eighteen to twenty large pale lilac-coloured campanulate flowers. Upon one of these side branches about fifty racemes were counted, and the show made by such profuse flowering may be well imagined. Although of easy cultivation in a warm greenhouse, the following points must be attended to flower it well, viz., to promote a vigorous well-ripened growth during summer (here it enjoys all the sun possible to give it), whilst growing a fair amount of water is afforded, the quantity being reduced towards the autumn, and during winter almost entirely withheld. No water was afforded the plant growing here, for about six weeks, and still the foliage remains fresh. The plant is rather variable in the colour of its flowers. *R. L. H.*

METHODS OF PROPAGATION.

(Continued from p. 36.)

BY MEANS OF ROOTS.—I have already given some methods of plant propagation by means of the stems and leaves. I will now descend into the soil, and afford my readers the chief points of propagation by the roots, specifying some of the subjects increased in this manner in nurseries. It may be taken as a general aphorism that all trees and shrubs that throw

up suckers or shoots from the roots freely can be increased by means of cuttings of the roots; and in some nurseries the Paradise Apple, Quince, and other fruit-trees are so propagated, though the methods already given are, in my estimation, preferable, if not better. The theory of root-propagation is that when the root-cuttings of certain plants are bedded in soil, the wound-part soon begins to callus or form granular cells, from which adventitious roots at the base are developed, while those at the upper part form adventitious buds, which eventually lengthen into shoots.

It remains only for the propagator to furnish the root-fragments with a suitable location, and to see that the conditions of moisture and temperature are constant and suitable, to assure success.

As a typical subject for this sort of treatment, I will first take the Dwarf Almond—*Amygdalus nana*—the pretty pink flowers of which are welcomed as one of the harbingers of spring. On lifting a strong clump of this, it will be found to consist of a mass of interlacing roots. Now, if in the early autumn, the stoutest of these are selected, divided into pieces about 6 inches long, and bedded in some generous soil, with which some sharp sand has been incorporated, the cuttings will grow the following summer, and next season they will have become strong enough to flower.

Quite opposite to this is *Desmodium penduliflorum*, the roots of which descend straight into the soil to a considerable depth, which being got up, and cut into lengths, will make plants in time. Another member of the same natural order—*Heylesarum multigermum*—is a fine novelty, and is increased by the same method.

Among plants recently introduced, none excels some of the Japanese *Fatsias* (*Aralias*) in handsome foliage. Of these, the well-known *A. Sieboldii*, though noble in appearance when it attains a fair size, is by no means the most handsome, though its being an evergreen is an advantage. The varieties I have in my mind are deciduous in character, with similar 5-lobed leaves, but too tender I fear for our sometimes severe winters. I allude to *A. Maximowiczii*, and *papyrifera*, and others introduced much earlier, and of a totally different character of foliage. *A. japonica* and *A. spinosa* [This is hardly *Ed.*], the exceedingly handsome bipinnate foliage of which, gives them a distinct and very attractive character, when planted singly or in small clumps on the lawn or in the shrubberies. Another plant put upon the market in recent years by a French firm, and named *Dimorphanthus mandchouricus*, may also be increased by root-cuttings. I confess I am not botanist enough to distinguish between this and the *Aralia japonica*, introduced late in the eighteenth century, but I have not seen the inflorescence of *Dimorphanthus*. I can say this in its favour, however, that treated as a sub-tropical plant and associated with *Musa Esote* and *Yuccas*, or *Cannas*, it has an unique effect in the ornamental garden. The *Ailanthus* (Tree of Heaven), and the noble *Paulownia*, can also be propagated by cuttings of their roots. *Experience*.

(To be continued.)

THE CHRYSANTHEMUM TRADE.

In the *Chrysanthemum* nurseries cutting-striking is in full swing; and the extent to which cuttings are sent by post is something extraordinary. Cuttings are offered at a cheaper rate than cutting plants, and many growers, preferring to have the newer varieties early, order them as cuttings, taking the chance of striking them. In order to supply cuttings, plants are grown in the open air all the summer and autumn, and then, as the Christmas season is approached, these are lifted, taken into a warm house, and planted in beds on the centre and sides, and covered with soil to the extent they were when growing in the open. Cuttings from such plants are short, stocky, and hard, and are preferred before those taken from plants which have bloomed in pots, and been grown strongly by the application of fertilisers.

The postal facilities granted in late years have given a great impetus to the cutting trade; the

cuttings, when taken off, are tied up with some moist moss about their base, placed in small, though light and strong wooden boxes, and forwarded long distances in perfect safety. Mr. H. J. Jones, of Lewisham, who has largely developed the cutting trade, states that it is the newer varieties in particular which are in brisk demand, and but comparatively few of the older favourites. So many new varieties are now sent out, that it is necessary, on the part of any grower for sale, to order the whole of them, and take his chance of having 10 per cent. or less of really good varieties. Then, as some of the newer varieties require three and four years' culture before they are developed sufficiently to be seen at their best, a number of inferior sorts, some of which are to be found in most new sets, have to be grown during the time, and be thrown away at last.

The striking of cuttings have been going on for some time; but is now in the full flow of activity. Already nicely-rooted plants are in small 60-pots for early orders. To succeed these can be seen hundreds of little shallow wooden boxes, which contain three dozen or so of cuttings, some well-rooted; others beginning to put forth root-fibres—many only just inserted. In a temperature of 50° or so, such cuttings soon make root, and then comes the process of potting off ready for the spring trade. As the demand for new varieties indicates the continued popularity of the flower, then it can be safely asserted that it is as widely grown as ever. *Chrysanthemum* societies are constantly being started in suitable localities, and it is found that exhibitions of *Chrysanthemums* are among the most successful financially. Autumn flowers, and especially the *Chrysanthemum*, appear to hit the popular taste much more than those which appear in spring, perhaps it is because human nature holds most closely to what is passing away, as autumn changes to winter, rather than to what heralds the approach of spring. *R. D.*

THE ROSARY.

THE VAGARIES OF THE ROSE.

Is not this a very ungalant term to apply to our beautiful queen? I think not, for beauty is always allowed to be capricious, and accountable to no one for her caprices, which are oftentimes quite inexplicable, and for which people never think of calling her to account. And has not an old Latin poet said that she was "*semper mutabilis*?" and one of our English poets has imitated him by calling her "uncertain, coy, and hard to please," so that I think we are not to be surprised if we find even the queen of flowers departing from the normal rules that govern her doings and for which we can find no adequate reason. These are especially of two kinds, variations in habit of growth and variations in the colour of the flowers. The former are generally called climbing varieties, and the Roses which have made this change, although strictly speaking they are not climbing, for they are not like those plants which in one way or another laid hold of support, but are simply rampant growths which have originated we know not how; the latter are changes in colour which take place perhaps oftener than we imagine, although they may pass unnoticed. Some examples of this climbing habit are very remarkable: take, for instance, *Devoniensis*, a small and moderate grower, which was raised by Mr. Foster in 1838, and was in many places, on account of its constitution, difficult to keep. But twenty years afterwards, in 1858, a plant in the garden of Mr. Pavit of Bath, sent up a strong and vigorous shoot, and so attracted his attention, that he determined to bud from it; he found it to be fixed—that is, that the plants budded from this shoot partook of its character, and it is no unusual thing to find shoots now from 15 to 20 feet, while at the same time flowers are produced in greater abundance [?], and maintain the character of those on the parent plant. It was distributed by Pavit, and I have never found any plants going back to their original form; the same variety has sported in like manner in two or three other places, but none of these have been

equal to the original one. People are sometimes complaining of their not being as vigorous as represented, while others deny its floriferous character, but I have never known these complaints to be made in the case of Mr. Pavit's strain. Other Roses, both amongst the Teas and hybrid perennials, have started off on the same track. Some years ago Messrs. Keynes, Williams & Co. brought out a climbing Niphetos, also in its normal condition not a vigorous grower, and described in the National Rose Society's Catalogue as tender, which many cultivators have found it; but I have seen shoots of the climbing variety 20 feet long, and stout and hardy, nor does the type seem in any other place to have made a departure from its normal condition. There are other Roses of which we have climbing varieties. There is, for instance, a charming Charles Lefevre, a climbing Capt. Christy, a climbing Jules Margottin; but it is

or, as we used to call it, H.P. La France, has sported off into the nearly white Angustine Guinoiseuse and the deeper-coloured Duchess of Albany; that old and favourite Tea, Souvenir d'un Ami, has in the same manner sported off to Souvenir de S.A. Prince. Thus Comtesse d'Oxford has given us a curiously striped Pride of Reigate; while Messrs. Harkness & Son obtained from Heinrich Schultzeis, a very beautiful striped Rose, which they have called Merrie England. Then Baroness Rothschild has also been sported, and has given us Mabel Morrison, nearly white. Merveille de Lyon, pure white; but some doubt has existed with regard to this flower, some contending that it is not a sport, but a seedling, and in proof of this they point to the very different shape and form of the flower; it may, perhaps, be the one exception which is said to prove a rule, for if it be a sport it is the only instance of which I am aware in which the

one they will go occasionally back to the original, and also that from La France itself sports may often be cut; therefore great care ought to be taken before putting any of them into commerce. I do not pretend to know what is the cause of this sporting, but it has given us many beautiful varieties of Roses.

Recently a very curious vugary has been noticed in the Rose-ground of Messrs. Frank Cant & Co. of Colchester: all Rose-growers know and admire the beautiful yellow Harrisoni, and have lamented it is only what is called a summer-flowering kind; but in a large batch of them Mr. Cant found three or four plants that bloomed very freely in the autumn—he budged from these and found that the plants retained the same character, so that we shall have, it is to be hoped, an autumn flower sport of this beautiful Rose.

Beside being careful about not distributing any of the sports until they are permanently fixed, growers ought to avoid the error of sending out as seedlings what are only sports; this has been done, and I cannot think that there is the same credit to be attached to the fixing of a sport as there is to that of raising a seedling—one is merely a freak of nature [a more or less complete reversion to some earlier form, Ed.], the other may be the result of careful and scientific manipulations. Anything that adds to the beautiful varieties of Roses which we now possess, may be hailed with pleasure. *Wild Rose.*

THE CULTIVATION OF DAFFODILS IN POTS.

PERHAPS the most valuable genus of flowering bulbs for cultivation in pots for winter and spring-flowering is the Narcissus. Despite the ease with which they can be grown, the beauty of the blooms, and in some cases their agreeable odour, little has been done with them in gardens beyond planting them in borders or beds. However, the tide is turning in their favour, and Daffodils are now being forced into bloom for market purposes in almost as great number as Tulips and Hyacinths. A peculiar fact in connection with the Narcissus family is, that while the so-called Polyanthus Narcissus (N. tazetta varieties) were for years strongly recommended for forcing, the Trumpet and other sections remained unnoticed; and for actual forcing there is little doubt that the "bunch-flowered" section of Narcissus is one of the least suited for this kind of work. Still, giant bulbs were produced year by year, and it was considered the right thing to do a dozen years ago to order a supply of these with the other bulbs. Suddenly, however, it became known that other species would force much better, and afford generally better results. Ten years ago it was considered early in the season to get flowers of forced Daffodils in February, whilst at the present time the last week of the year sees plenty of flowers of Narcissus.

The points to be noted in securing early flowers is that the right species or varieties be chosen, as early as they come over from Holland, and that they be potted forthwith. The point to be observed, the chance of failure is small. With plenty of roots made while the bulbs are in the open air in a bed of coal-ashes or tan, the flowerscape is more likely to prove early than is the case with late-potted bulbs. There is too little attention given by gardeners to this important feature of early flowering, and bulbs are not planted nearly so soon as they should be, but instead they are rushed into heat in part unfurnished with roots, with results that are never very satisfactory. The soil for Narcissus is not of much consequence, so long as it is of a fairly sandy nature and not wet when used; and old potting-shed materials, if duly sifted, and mixed with a small quantity of fresh loam, fulfil all the requirements of the plants. For some years I have employed the mould taken from dissolved Cucumber beds, with fairly good results. One of the most fortunate things in connection with the forcing of the Narcissus, is that the commoner and cheaper varieties are the best for the purpose. Take for example the double yellow-flowered pseudo-Narcissus, which is to be found in so many of the cottage-gardens in England and Wales, and which as a double-flowered variety is still the best in colour and shape. Then there is the now well-known Tenny Daffodil, a bright yellow, with a sturdy trumpet, which forces readily; while closely following it comes the more expensive though larger variety known as Ard Righ (Irish King), the large flowers of which are very handsome. Among the paler forms, N. p. n. Prince pius as

FIG. 29.—IRIS HYSTRIX.

(See Report of the Royal Horticultural Society, p. 114, vol. 3.)

a somewhat curious thing that there are no climbing varieties of such strong and sturdy growers as Paul Neyrou and Etienne Levet. In all the cases that I have noticed there is no change in the character of the blooms, and the whole proceeding seems to me very inexplicable; it cannot be the stock on which these climbing specimens have been budged, for myriads of the same Rose have been budged on all kinds of stocks—Maunett, seedling Briar, Briar cutting, Polyantha, &c., without in the least causing them to start off on their own account.

The subject of sports, so far as colour is concerned, is also a difficult one to explain. Some kinds, both of Teas and hybrids, apparently have been more inclined to do this than others; Catherine Mornet, for example, amongst the Teas. This has sported off to the beautiful white Bride, and the pink-flowered Waban, both of American origin; while the latest sport obtained by Mr. Brown, of Reigate, Muriel Grahame, shows the possibility of still further departures in this direction. So, again, the hybrid Tea,

shape and build of the flower have been altered—when caught at its best it is a most beautiful Rose, but the centre is somewhat faulty, and it is very apt to show the eye. These sports in colour are not always permanent, and are a great disappointment to the Rose-growers. A very notable example of this is Sir Rowland Hill, a very beautiful maroon or deep claret sport from Charles Lefevre; this, when exhibited by Messrs. Mack & Son at the exhibition of the National Rose Society at Edinburgh, some years ago, obtained the Society's Gold Medal, though I believe it was exhibited as a seedling, which certainly it is not. It is a flower of most attractive colour, but unfortunately has a great propensity to "hark back"; it is seldom seen in the exhibition stands, and I have been told by those who grow it in quantity that perhaps in sixty or seventy plants you do not get more than one or two which are true to character—it therefore becomes valueless as a sport. It is the same sometimes with the sports from La France: those who grow it in quantity have told

charming flower, easily grown, and almost indispensable in early work. The single Van Lion is likewise a good yellow; while Golden Spur, a huge golden flower, is finer still. Some of these single forms have delicate perianth segments, requiring care in forcing them not to place the bulbs in a temperature that is too high, as this, with much overhead moisture, quickly spoils the blooms. Countess of Annesley is a faulty one in this respect, because the segments frequently lie upon the trumpet, and prevent the escape of moisture. Moisture at the root is desirable, but as soon as the some bursts overhead syringing ought to be discontinued, and the plants removed to a house with a temperature of about 50°. The same remark applies to many of the *N.* incomparabilis group, and, indeed, is generally applicable to those with rather thin perianth segments. Among the white forms, *N. poeticus*, and *N. p. ornatiss* require to be brought along steadily—in indeed, a temperature of 45° is the best to start with; and in the same degree of heat quite a host of other species and varieties may be grown to perfection. *J.*

THE WEEK'S WORK.

THE FLOWER GARDEN.

By CHARLES HERRIS, Gardener, Dropmore, Maidenhead.

Planting and Pruning Climbers.—The following plants may still be planted:—*Chimonanthus fragrans*, a desirable subject for a sunny wall, whose period of flowering will soon be past for the season, when the necessary pruning should be performed. As it flowers on the young growths of the preceding year, the shoots which have flowered should be pruned to within two buds of the shoots from which they arise. If the allotted space be not filled, the leading growths should be tipped with wax, and then secured to the wall. Free growth should be encouraged, which is best done by affording the roots a top-dressing of new soil and manure. *Jasminum nudiflorum*, a plant that is now in flower, should have weak shoots thinned out, and others cut back as soon as it has passed out of bloom. The following subjects are adapted for planting against walls with a southern aspect:—*Choisya ternata*, an evergreen shrub with fragrant white flowers; it is a suitable shrub for planting throughout the south of England and similar districts. In some parts of Devon and Cornwall it flourishes as a bush without the protection of a wall. *Magnolia grandiflora*, evergreen; *M. conopsea*, and its varieties, *Soulangiana* and *S. nigra*, are excellent for planting against high walls, being plants of vigorous growth. *M. Campbelli* should only be planted in gardens in the south and south-western maritime counties. It has flowers of pale rose inside, and outside crimson. *M. glauca* is hardy anywhere—the flowers are white and fragrant. *Stantonia hexaphylla*, a small flowered, very sweetly-scented climber with dark green foliage; *Ribesportia foliosa*, a plant of shrubby growth, with fragrant white flowers; *Ceanothus cuneatus*, *Passiflora corulea*, and *F. Constance* Elliot may all be planted in sheltered situations against a south or west wall. Among hardy climbers, the *Clematis* ranks deservedly high, and may be planted in great variety. One of the most useful is the old *C. Jackmanii*, a very effective purple-flowered variety, blooming from mid-summer to late autumn. Where established plants of this variety are desired to cover a large space, the strongest growths of last year should only be shortened slightly, and the weaker ones cut back to one or two buds, but others should be cut back when a low flowering growth for covering arches or beds is required. Varieties of the *C. montana* type, which flower from ripened shoots of the previous year's growth, require but little pruning at this season, the removal of dead wood being all that is necessary, the required pruning being carried out when flowering is over. When planting climbers, the Sweet *Jasminum—Jasminum officinale* and *J. o. grandiflorum*—should not be forgotten, the latter with larger flowers and stronger growth. In pruning *Jasminum*, the young shoots of the preceding season require to be cut back almost to the base, the leader being allowed to extend if desired. *Jasminum revolutum*, a yellow-flowering species of strong growth, should be planted in a sunny and sheltered situation, where there is space for free development, and not pruned so closely as *J. officinale*, but some of the strong young growths tied or nailed in at nearly their full length. For covering a north wall, *Cratogeomys pyraeantha* is an excellent subject, flowering and setting its berries in profusion, which remain throughout the winter. Where a climber

with large and important-looking foliage is desired, and there is ample space, *Aristolochia siphon* may be planted in a good wide border. The well-known *Wistaria sinensis*, flowering in early spring, requires a considerable amount of wall or roof space for extension so as to show off the beauty of its flowering racemes. *Amelopsis Veitchii* and the common Virginian creeper should be planted for the rich colour of the autumn leaves. *Honeysuckles*, *Bignonia radicans*, *Escallonia macrantha*, *Forsythia suspensa*, and *F. viridissima*, and *Kerria japonica* are other subjects well fitted for covering walls or fences. The planting of *Roses*, both as climbers and in the open, should now be completed as soon as possible, unless they are growing in pots, when planting may be carried out later. *Fortune's Yellow* is an old variety adapted for planting against east or north walls. Climbing *Roses* trained to walls, fences, &c. should be pruned forthwith. The or nail in strong young growths at nearly their full length, cutting back all weak growths to one or two eyes.

Dahlies may now be put in a heat of 55° to 60°, for the production of shoots fit for making cuttings. If the roots are stood on the floor of a vinery, and moistened with the syringe, no soil covering is necessary. Slip off the shoots with a beel when 2 inches long, and insert singly in small pots filled with light sandy soil, and place in propagating-pot or frame in warmth of 65° to 70°, guarding against excessive moisture. Old stools of varieties of which no cuttings are wanted should be kept cool.

THE HARDY FRUIT GARDEN.

By H. W. WADE, Rayleigh, Essex.

Pruning and Training of Wall Trees one year Planted.—Upon the manner in which this is performed depends almost entirely the building up of productive and symmetrical trees. In fact, these remarks apply to fruit trees and bushes generally, but more particularly to wall trees. Up to within the last quarter of a century it was the custom to cut back the shoots of young trees to within two or three buds of their bases at pruning time, with the object of laying the foundation for a well-furnished tree, with the natural result that twelve months after planting the trees were little, if anything, larger or better than they were when received from the nursery. But this rather faulty practice has dropped into disuse, and "extension" taken its place, i.e., the formation of large fruit-bearing trees in as short a space of time as possible. To Mr. J. Simpson, of Wortley, is due the credit of having initiated the "extension" system, as well as indoors as in the open air; and during the short time which has elapsed since the early varieties this method has been ventilated in the pages of this and other journals. As the old methods still maintain their hold on the craft, I will briefly describe the new. The first spring after planting young trees on walls or in forcing-houses, and as soon as the sap begins to rise, the unpruned shoots are bent towards the ground, and secured in that position to the wall or trellis in the ordinary way, the bend starting from the point whence the first of the young growths should proceed—say, 3 or 4 inches from the base. The fact that this bending of the shoots gives to the flow of the sap, causes a number of wood-buds to push from each shoot, which serve to form a good-sized fan-shaped tree the first year. As a matter of course, as soon as the buds nearest the base of each shoot so treated have pushed into growth, the nails should be drawn, or the ties cut, as the case may be, and the shoots (main-shoots) spread out on the wall or trellis fan-wise, and loosely secured thereto, the young shoots being trained at proper distances apart over the intervening spaces, a judicious course of disbudding and pinching of the after growths being followed during the summer and early autumn months, with the object of developing the wood and fruit-buds, and inducing a balanced growth.

Peach and Nectarine Trees should be pruned forthwith. They only require the shoots made last year to be thinned out a little, retaining, of course, only those which are well furnished with fruit-buds, cutting back old ones, i.e., shoots made in 1895, to their bases, and shortening back weak shoots to a wood-bud situated just beyond the uppermost fruit-bud, or to three buds located together, the middle one of which is a wood-bud. Any unduly strong young shoots should be removed entirely where they can be dispensed with. The shoots which should radiate from the upper part of the stem should be trained at an equal angle; and at a not smaller distance than from 3 to 4 inches apart, which will allow of the

shoots of the current year being laid in between them by means of short lengths of the shoots of *Privet*, *Hazel*, &c. Where very strong young shoots cannot well be dispensed with, they should be bent towards the ground, and treated on the extension system.

THE ORCHID HOUSES.

By W. H. WATTS, Orchard Grower, Burford, Dorset.

Airides.—Some few species of *Airides* bloom in August and September, but most of them flower in the summer, yet the treatment of the plants as a whole is almost identical throughout the year. In a week or two it will be necessary to repot or top dress such as require more space or fresh material. Whilst the plants are in the potting-shed the minute brown scale often observed on the leaves should be wiped off with a sponge dipped in soapsuds; even if no scale be visible, the sponging will brighten up the leaves of the plant.

Angraecum sesquipedale, which may have gone out of bloom, should be sponged in the same manner, to remove scale and a fluffy sort of mealy bug which sometimes infests the plant and may be found on portions of the old foliage, close to the stem. Well-grown plants present a beautiful glaucous appearance, and unless absolutely necessary, sponging of the leaves should not be resorted to.

Phalænopsis.—At the present time several species are in bloom, viz., *P. amabilis*, *P. intermedia* Verel, and *P. leucorhoda*, and care should be taken of the small or weakly imported plants that they do not flower excessively. It is not always advisable to pinch out the flower spikes which appear, for fear that others may start later on when the plants commence to grow, and if the plant is healthy, the spike may develop, and then be cut off as soon as the flowers open. *Phalænopsis* should be afforded water carefully at this season, it being sufficient to sprinkle the sphagnum-moss lightly and the sides of the basket, and never let water lodge in the centre of the growths, for fear of the leaves becoming spotted.

Special Houses.—If a house can be set apart for such species of *Orchids* which are found to succeed under a similar kind of treatment, it is considered that their well-being, as then their culture becomes easier, and results are better than when *Orchids* of varied requirements are mixed together. This is particularly the case with species from Mexico, viz., *Mormodes lucinaria*, *M. pardalina*, *M. p. nicolor*, *M. luxatum*, *M. l. eburneum*, *Epidendrum nemorale*, *E. atropurpureum* (macrochilum), *E. alatum*, *Cyrtopodium St. Legerianum*, *C. Andersonii*, *C. punctatum*, *Cattleya Skinneri* and its varieties, *C. speciosissima*, *Schomburgkia*, *Arphyphyllum giganteum*, *A. spicatum*, *Oncotoglossum citreolum*, *Laelia macra*, *L. alba*, *L. autumnalis*, *L. Goodii*, *L. Marrottiana*, and *L. acuminata* (rhombacea). The varieties of *Laelia* are especially so numerous to mention here, but such distinct forms as *Barkeriana*, *Chamberlainiana*, *Schrodere*, *leanum*, *Veitchiana*, *Percivaliana*, *rosea*, *Hilli*, *Dawsoni*, *Sanderiana*, and *Stella* were all open at one time at Burford recently, and formed an interesting group. The majority of these Mexican *Laelias* have now finished blooming, and root-growth will soon begin; and before this occurs is the proper time to do any fresh potting or top-dressing that may be needed. Well-rooted plants and those with sufficient pot room need not be disturbed, unless the compost is stale. In surfacing remove the old moss from the roots before affording fresh materials. When re-potted established plants, the roots need not to be much disturbed, as to do that might cause a check, and the plants might not bloom again for a long time. Shallow pans, or baskets of teak are best, the plants being raised above the rim, and the materials firmly placed round the roots. These may consist of fibrous peat, a small quantity of sphagnum-moss, and a few large sticks that may facilitate the passage of water. When re-potted, afford them a light, airy place, and enough water to prevent shrivelling, any more than this causing the older roots to decay quickly. Till new growths are seen, and the roots have taken hold of the potting-stuff, the temperature at night should be kept at 55°, and by day with sun-heat 10° to 15° higher, with plenty of ventilation. In dull or continued rainy weather, the air in the house should not be humid. *Laelia flavo* and *L. harpophylla*, now sending up flower-spikes, will need but little water. *Brassia* *Cattleya* (*Laelia*) *Lindleyana*, now showing for bloom, succeeds in baskets hung up to the roof. The amount of water it receives should be gradually reduced when its flowers are fully expanded, and they will then keep fresh for a long time.

PLANTS UNDER GLASS.

By G. H. MAVEOCK, Gardener, Luton Ho., Luton.

Greivilla robusta.—Old plants may be cut down to within 6 inches of the ground, so that they may make nice plants for indoor decoration by the end of the season. When the plants have broken, select the best three growths, and rub off the remainder. Seeds of this plant may be sown at the present date on a brisk bottom heat, the seedlings being pricked off when large enough to handle, still keeping them in heat for a time.

Ferns.—No time should be lost after this date in dividing where necessary, and re-potting the plants of the various species and varieties. The method of increasing the more popular *Adiantums* and *Pteris* is by means of spores. Select fronds whose spores are of a dark brown colour, these being very minute round or oval in shape. Sow them without delay on peat that has sterilised by heat, and then buried in a sack in some part of the kitchen garden to moisten. Having mixed a quantity of this peat with sharp sand, proceed to fill well-drained pans or broad pots, pressing it firmly, and having watered each panful, stand them aside to drain, and when moderately dry upon the surface, scatter the spore thinly, cover with a sheet of glass, and put over all some moss. The best method of affording water when the soil gets dry is to place it on an inverted pot in a vessel of warm water, the pan being sunk about 1 inch, and allow it to remain till it is considered that the soil has become sufficiently moist. The spore-pans should remain in the propagating-house till the seedlings are large enough to be pricked off into small pots. In potting the plants, the pots should be clean, and well drained. A suitable potting soil is one that consists of one half fibry loam, and the other half peat, with a liberal quantity of sharps and leaf-soil. Ferns from spores sown last year, which are now in 3-inch pots, may be repotted into 5-inch ones, and so on in proportion, a few of the oldest plants being discarded, so as to make space for the young generations. Ferns, young and old, require firm potting, but the soil must not be made hard with a rammer. *Davallias* in variety may be increased by cutting the rhizomes into good long pieces, and pegging these down firmly on the soil, or on the dead stems of Tree-Ferns. These plants may be placed at the cooler end of the fernery. Epiphytal species, namely, *Platycoerum*, do well if tied or nailed on to blocks of half-charred wood, such as that of the Apple, Oak, or Oak, previously well covered with peat and sphagnum-moss. I do not recommend the use of cork, it being, in my opinion, too dry for Ferns during the summer. *Gleichenias* may be increased in the same manner, or by dividing old plants into two or three pieces. *Gleichenias* thrive better in pans than pots; and in the potting soil, only one part loam and more leaf-mould and sand should be made use of. When the potting is finished, the temperature of the house should be raised to 55° by night, 60° by day, and the air kept rather moister.

Cyclanthes.—A part of the stock of these tubers may now be potted in pots just large enough to hold them, shifting them afterwards according to the size required. Place them in the stove, or pit having a similar degree of warmth, and when the roots have penetrated the new soil, syringe them daily. Some gardeners shade the plants during the hottest part of the day, others do not.

Gloxinias.—Tubers for flowering early should be potted up forthwith, in a mixture of one-half leaf-mould and one-half peat, and plenty of sharp sand. Apply water sparingly at the first, and keep them in a moist atmosphere, not syringing them overhead, but well damping the walls and staging frequently. *Gloxinias* take abundance of water during the growing season, and great care should always be taken in checking thrips. If they are wanted in flower for a long season, successive batches should be potted up at intervals of a fortnight or thereabouts, relying on seedlings raised from seed sown in January.

FRUITS UNDER GLASS.

By F. HANCOX, Gardener, Epsom-Castle, Leathers.

Fines.—Fruiting plants should now be afforded rather higher temperatures, viz., 70° at night to 80° to 85° by day with sunheat, and a bottom-heat of 85° to 90°. To encourage the plants to develop fruit, maintain a moist air about the plants by damping between the pots, walls, &c., twice daily, and keeping the evaporating pans filled with mild liquid-manure; a sprinkling of some safe and suitable artificial manure should be occasionally afforded, which should be washed in with clear water at a temperature of 95°.

The fruits should be supported in an erect position by wooden stakes and broad blast ties.

Successions.—Plants that were started to grow about the New Year, and now exhibiting the embryo fruit, should be kept fairly moist, but not allowing the soil to become very wet, or the flowers may not all set, the result of which is mis-shapen fruit. Should any of this batch not yet have thrown up a flower-spike, the soil must be kept dryer until they do so. To keep it moist is to promote leaf-growth only. Keep the temperature at the above figures, and as the days lengthen and the sun gains power, increase the amount of ventilation, carefully avoiding sudden changes, as a check now will influence the proper development of the fruits later on.

Potting Successions.—If the soil was prepared as recommended in an earlier (clematis) potting may proceed forthwith, choosing the best and strongest plants, and those which have filled their pots with roots. Such plants may go into fruiting-pots of 10 or 12-inch diameter, according to the size of the plants. Before potting a plant, sprinkle a handful of crushed bones and a small quantity of soot over the cracks, and having soaked the balls, if dry, in warm water, allow them to drain, then gently disengage the points of the roots, strip off a few of the lower leaves, and place the top of the ball a little lower than before, and ram the soil fairly all round it. After the plants are potted, they should be plunged in a bottom-heat kept steadily at 85°, the top-heat being 60° to 65°. Withhold water from them for a few days, but keep a growing atmosphere by frequent damping of the bed, walls, floors, &c, and ventilate sparingly till growth begins, then give air more freely, or the plants will get weak and spindly. A very light shading may be used in the middle of the day when the weather is bright. A slight sprinkling overhead at closing time will be of great assistance at this stage; any available suckers may be potted up, and as a means of obtaining suckers of varieties that do not produce them freely, some of the stools may be trimmed up and plunged in a brisk bottom-heat.

THE KITCHEN GARDEN.

By W. POPE, Gardener, Highclere Castle, Newbury.

Lining the Soil in old Kitchens Gardens.—Usually the soil of a garden which has existed for a great number of years contains a great deal of undecayed vegetable matter supplied by repeated dressings of manure, the roots of crops laid in the soil, &c., which in its turn state is productive of many evils, and no better corrective exists than quick-lime. The present season, and other times when the land is being dugged or has been dug, is a good time to apply it with the manure, or as a top-dressing. Its action is to render the vegetable matter more suitable to serve as the food of plants, to aerate the soil, and destroy, by its caustic action, insects, their eggs and pupae. The rate at which lime fresh from the kiln may be applied is from 30 cwt. on light gravelly soils to 2 tons for clay land per acre. It should be spread evenly, and used whilst fresh. Lime from the purifying chests of the gas-house is often recommended as a dressing for foul land, but it should be afforded in the autumn, and left on the surface for a few weeks before being dug-in; the same rule applying to dressings of chalk, which should be put on in time to be well pulverised by the elements before seed sowing or planting.

Renovating the Paths and Edgings.—Where Box is used as an edging plant, the present is the proper time to carry out any mending or relaying that appears to be required. When relaying, the old edgings should be entirely taken up in the part to be operated upon, and the ground in the line of the edging deeply dug and freshened up by some soil being added from the adjacent quarters or borders; and when dry it should be well trodden, levelled, and beaten to the proper level, i.e., a point level with the lower part of the walk, supposing that to be of its proper level. Then pull the old Box plants into pieces, 3 to 4 inches long, trim the tops and roots, and relay it rather thinly, and very evenly, making it very firm about the roots, against the vertical side of a trench cut with a spade, taking care in making the latter to preserve the true width of the path. As the relaying oblige the garden to shovel up the gravel into heaps and ridges on the walks operated upon, and there is obviously much soil brought on to them, re-gravelling is always necessary more or less, and it is as well to get this sort of work done before the more busy season comes on. A walk may have the entire coat of old gravel wheeled away, and this is always a advisable if it be old, and consequently

much mixed with mould; or a layer of the old materials, 1 inch thick, may be removed; or where the gravel is in fairly good condition, it may be turned with digging-forks, and made fresh-looking with a sprinkling of new gravel. This holds good for pit-gravel, sea-gravel, and shingle-made walks. If a walk does not dry quickly after-rain, it is badly drained, or not at all; but as the re-making of such walks is a long job, it should be deferred to October, November, or December. The best kind of edging is made of stone, or cement, or similar hard materials, and then with "Weed Killer" a walk can be kept in good order for little expense.

Parsnips.—When the soil gets sufficiently dry to bear being trodden upon, a few rows of Parsnips may be got in, in drills less than 2 inches deep, drawn at 1 1/2 foot apart, the seeds being dropped in pinches of three to four 1/4 foot apart for large, and 1 foot for medium varieties. By sowing in this manner thinning is more expeditiously performed. If very fine roots are required for any purpose, holes should be made 2 1/2 inches deep, and 1 1/2 inches apart, with a cross-bar or iron-shod two-handled dibber, filling these with finely-sifted, rather light soil, such as old potting-soil, made firm, and a few seeds pressed on to the top of each, taking care to thin to a single plant. Do not sow seeds if the ground is sticky, but wait till it is sufficiently dry. For roots of medium size and of fine quality, nothing surpasses *The Student*, and for extra large roots *Maitese*, or *Dobbie's selected*.

Parsley.—Some Parsley seed may be now sown, so long as it near a path, where it may be gathered without any treading on the soil. A light dressing of soil and soot should be sown over the land before drawing the drills, 1 inch deep. Sow thinly, cover with fine soil, and this as soon as the plants are large enough to handle.

THE APIARY.

By E. S. B. B.

The County Season and Early Sections.—It is well known that bee keepers throughout the country are considering what can be done with reference to the contest for the County Trophy at the Royal Show to be held at Manchester. That there will be a splendid exhibit is beyond doubt, and proud will be that county which secures it. At the same time no better method could be adopted for showing to the public the great importance of the bee-keeping industry throughout the country; and it should have the effect of pushing on the local people, and extending the work in the proper direction. As the show is held in June, and majority of the bee-keepers have disposed of their best stocks; and even if some have not done so, unless the stocks have been kept in a fairly even temperature, they will have become more or less emaciated, which will render them totally unfit for an exhibit of this kind. With this object in view, we should prepare our plans so that as soon as the honey-dow commences, we may have our best bees working away in the sections, and so be in the position of getting the largest quantity in the shortest time. Sectional honey, of course, must be the first consideration, and to enable this to be done by the first week in June the brood chamber must be contracted, five or six frames only being left, so that the bees will commence in the sections above, instead of looking after the brood chambers below. Very early swarms may be depended upon to secure a crop off first-class sections. Leaving out the question of the show, we should by this time have made up our minds what it is we intend to do this year—whether we will compete with honey in sections, or extracted. Of course, it is no use for me to advise one or the other, as that which finds the readiest market decides the choice.

The Hive-entrance.—All dead bees should be cleared away when observed, but when none is seen the stocks are best left untouched. The weather we have had lately will have caused the bee-keeper a good deal of anxiety, but as long as the bees are seen flying from their hives we may assume that all is well; but where a quantity of dead bees are seen, and apparently there is no life about the hive, an immediate examination should be made, and the necessary steps taken to keep the stock of bees alive.

Quilting.—Place more quilts over the hives so as to keep the brood-nest warm, as in warm places breeding will have commenced, and as remove all wet quilts, and repair roof if leaky. Cakes of warm candy may also be given, a peep will tell you if bees are about and require it; but do not interfere with them yet. Nothing is more searching than snow-water, and a serious amount of harm may be done if a leak happens to convey the water to the warm brood-nest of a closely-packed cluster of bees.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER. Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

THURSDAY,	FEB. 18—	Linnean Society meet. Royal Gardeners' Orphan Fund: Annual General Meeting at Ambrose's Hotel, Fleet Street.
FRIDAY,	FEB. 19—	Performance of "Dorothy" at St. George's Hall, in aid of the Gardeners' Royal Benevolent Institute.
SALES.		
MONDAY,	FEB. 15—	Greenhouse Plants, Spiræas, Ferns, &c., at Frotheroe & Morris' Rooms. Unsorted Stock of Border Plants, at Stevens' Rooms.
TUESDAY,	FEB. 16—	Roses, Montrichets, Iris, Anemones, &c., at Frotheroe & Morris' Rooms.
WEDNESDAY	FEB. 17—	<i>Lilium aratum</i> , <i>Burpee's Lilies</i> , <i>Begonia</i> , <i>Azaleas</i> , &c., at Frotheroe & Morris' Rooms. Roses, Fruit Trees, Shrubs, and other Plants. Also Palms, <i>Azaleas</i> , <i>Stevia</i> and Greenhouse Plants, from Ghent, at Stevens' Rooms.
THURSDAY,	FEB. 18—	Hardy Perennials, <i>Gloxinias</i> , <i>Clematis</i> , &c., at Frotheroe & Morris' Rooms. Trade Sale of <i>Liliums</i> , <i>Bulbs</i> , <i>Plants</i> , &c., at Stevens' Rooms.
FRIDAY,	FEB. 19—	Established and Imported Orchids, at Frotheroe & Morris' Rooms. Scientific and Photographic Apparatus, at Stevens' Rooms.

AVERAGE TEMPERATURE FOR THE ENSUING WEEK, deduced from Observations of Forty-three years, at Chiswick.—39° F.

ACTUAL TEMPERATURES:—

LONDON. February 10: Max., 51°; Min., 45°.
PONTYPOOL.—February 10 (6 P.M.): Max., 57°; Scilly; Min., 39°. Aberdeen.

TEN years have elapsed, as the President reminded his hearers at the annual meeting of the Royal Horticultural Society, since the Society quitted South Kensington under circumstances of great irritation and some humiliation. A strong and active body of the Council fought vigorously for the rescue of the Society, which then seemed on the verge of destruction; and their labours, added to subsequent good management, have succeeded in placing the Society in a position more favourable than could have been expected by the most sanguine. Among the most efficient causes for this have been the lowering of the subscription fee, and strict adherence to horticulture pure and simple. The Drill Hall in which the committees meet, and the room in which the annual meeting was held, were secured by a small sub-committee consisting of the late Mr. GEORGE DEAL, Mr. GEORGE PAUL, and Dr. MASTERS, and nothing more suitable has yet been found. Till that time the valuable collection of books was huddled away in an inaccessible corner at South Kensington. Now it is conveniently housed, though it experiences the usual fate of growing libraries in the form of inadequate space. Still, as our illustration (fig. 31) shows, it is a vast improvement upon the state of matters ten years ago; and the room, about half of which is shown in the photograph, is in these placid times large enough to hold the annual meeting of the Fellows. The great majority of the books, and most of the portraits, are held in trust for the benefit of horticulturists in general, and of Fellows of the Royal Horticultural Society in particular, by the Lindley Trustees. The Trust Fund is very small, so that donations whether of funds or

of books are very welcome. The catalogue is now going through the press, but it can hardly be issued till there is a larger balance at the bankers, and we earnestly hope that further help will be forthcoming, and that those of our readers who have no further need for their horticultural or botanical books or pictures will remember that they will be welcomed by the Trustees, and that to be inserted in the Catalogue they must be sent in at once to the Librarian, Lindley Library, Royal Horticultural Society, 117, Victoria Street.

The Drill Hall, which is hired for the fortnightly meetings, and the Lindley Library, with one small office annexed, constitute all that the Royal Horticultural Society can produce in the shape of a Horticultural Hall or Institute. It is very lamentable, but recent experience has shown that the time has not yet come when we can realise anything better.

We have already published the Report of the society and commented upon it (see p. 114), so that very little needs to be said now. The President, in moving its adoption, followed the lines of the report very closely, and was naturally and justifiably jubilant and grateful to the secretary, officers, and committees, all of whom came in for a well-earned tribute of thanksgiving. Chiswick has been put into thorough order; old, useless sorts of fruit trees have been eliminated, and plants of interest instead of rubbish are circulated among the Fellows. All this is very satisfactory, so far as it goes, but now we want an opportunity to get the Fellows to Chiswick. The Society spends about £2000 a year on that garden, including the large sums required to repair the wear and tear of time, and the enforced neglect of former days. A garden costing so much ought to be worth seeing, but only a very few are likely to visit it, unless some special inducement to do so is offered. The Congresses and Conferences that were held in recent years, are among the most honourable records of the Society, and their results are still most valuable to the horticultural world.

Last year not a single meeting of this kind was held, except the fruit show at the Crystal Palace. We lately threw out a suggestion that a joint meeting of all the committees might be held at Chiswick during the course of the summer to discuss matters of common interest, such as the work done at Chiswick, the number of awards to be given, the principles to be followed in their allotment, questions of nomenclature, questions affecting the relations of the committees one to another and to the Council. Some such subjects as these would serve as a basis for useful discussion, and the remainder of the time might be taken up in an inspection of the establishment. To deprive the Fellows of the Conferences, and practically debar them from taking part in any way in the work at Chiswick, is to stifle rather than stimulate interest.

Reverting to the topics that were mentioned at the annual meeting, we note that the President announced the intention of the Council to confer a Victoria Medal, or something of the kind, on meritorious horticulturists, but nothing was said as to the number of the recipients, nor as to the principle to be followed in their selection, and no Fellow present had any remark to make upon so novel a proposal. This obviously will have to be most carefully considered, and when determined, rigidly adhered to. The bestowal of these medals might well take place at Chiswick in accordance with our suggestion above stated.

There was very little discussion upon this or

any other subject, the Fellows feeling perhaps the force of the adage—happy is the nation that has no history; at any rate, they seemed to rest contented with the Report and statement of the President. Professor FOSTER gave formal voice to the satisfaction that was felt, but stated, truly, that the Society has by no means reached the limits of its usefulness.

Votes of thanks were duly passed, and all seemed over, when a gentleman rose to advocate the culture of Apples in Kent, and the manufacture of cider therefrom. In connection with this, he advocated the establishment of an "Arbor Day," when the local children should be instructed each to plant an Apple-tree. The speaker was anxious that the Royal Horticultural Society should lend their influence in encouraging the scheme; but the President, whilst announcing that the Council would be willing to consider any definite proposal laid before them, evidently thought that the cider-makers needed no instruction from the Society.

LINNEAN SOCIETY.—An evening meeting will be held on Thursday, February 18, at 8 P.M., when the following papers will be read:—I. "On Certain Points in the Anatomy and Morphology of the Nympheæceæ," by Mr. D. T. Gwynne Vaughan; II. "The Adhesive Discs of *Ercilla spicata*, Moq.," by Mr. T. H. Burgeale.

FARMERS AND ASSESSMENTS TO LOCAL RATES.—We have been furnished by the Board of Agriculture with a leaflet containing information regarding the basis upon which the assessments of the poor-rate—and practically of every local rate levied under the general law, where the Union Assessment Acts are in force. The proper steps to be taken by persons objecting to the assessment to the poor-rate are briefly set forth, as also with regard to other rates other than the poor-rate. There are other matters which frequently are of great importance to market gardeners, nurserymen, allotment-holders, and cultivators of hardy fruits, namely, the assessment of such land to a general district rate in urban districts, and of a separate rate for special sanitary purposes to rural districts. Copies of this leaflet are to be obtained free of charge and post-free on application to the Secretary, Board of Agriculture, 4, Whitehall Place, London, S.W. Letters of application so addressed need not be stamped.

BOTANICAL MAGAZINE.—The February number contains coloured illustrations of—

Myrceneola Antoinæ, Baccari, t. 7517. ¹/₁₀₀₀—A those very singular tropical Rubiaceæ shrubs forming globose tuberous expansions at the base of the stems, inhabited by ants, which repay the hospitality they enjoy by the protection they afford against marauders. The plant is a native of Thursday Island, Torres Straits.

Mastillaria Sanderiana, Rehb. f., t. 7518.—A native of the Andes of Ecuador, the finest of its genus, having flowers 4 inches across, with broad white segments, richly spotted with purple at the base.

Ligustrum coriaceum, Carrière, t. 7519.—A species presumably of Japanese origin. It is of very slow growth, and has densely crowded, thick, evergreen, ovate leaves. We have always found it hardy near London, but have never seen it in flower.

Hemipilia anethystina, Rolfe, t. 7521.—A glabrous terrestrial Orchid, native of the Shan States. The single leaf is sessile cordate, ovate acute, green, spotted with purple. The erect scape bears a many-flowered raceme of small flowers, insignificant but for the prominent white lip, which bears a magenta blotch. Flowered at Kew.

Panicum heliogramma, Kerker, t. 7520.—A West Hindayan hardy Bromiaceæ perennial, with long-stalked, hoary, lanceolate leaves, and loose, many-flowered cymes; the individual flowers about half an inch long, drooping, bell-shaped, with a pink tinge and blue limb. Kew.

FIG. 30.—FERNERY IN THE PLEASURE-GROUND AT LUTON HOO. (SEE P. 95 OF PREVIOUS ISSUE.)

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We have the pleasure to announce that a performance of the comedy-opera, "Dorothy," has been arranged to take place in St. George's Hall, Langham Place, W., on Thursday next, February 13. The performance is in aid of the special fund being raised by the above Institution to commemorate the sixtieth year of HER MAJESTY'S reign, and will be given by the members of the Westminster Amateur Operatic and Dramatic Society, with full orchestra. THE VICTORIA ERA FUND is intended for the temporary assistance of candidates awaiting election, and is deserving of all help possible. Particulars and tickets for the performance may be had from the Hon. Secretary, H. MORGAN VEITCH, Esq., 16, Clifford's Inn, E.C.

ULSTER HORTICULTURAL SOCIETY.—At the last committee meeting of the above, it was decided to celebrate the Diamond Jubilee of the QUEEN this year by offering £100 and three medals for competition in forty-eight cut blooms of Japanese varieties of Chrysanthemum at the next show to be held at Belfast on November 16 and following day. The money is to be divided into seven prizes as follows:—1st, £40 and gold medal; 2nd, £25 and silver medal; 3rd, £15 and bronze medal; 4th, £10; 5th, £5; 6th, £3; and 7th, £2. The committee decided to make this class, and a few others, open ones to the gardeners of the United Kingdom. The prize is to be called the Victoria Jubilee Championship, and is presented by the Lady Mayoress of Belfast, and the ladies of Ulster.

CARDIFF HORTICULTURAL SOCIETY.—This Society held its annual general meeting on the 4th inst., when a large number of gentlemen interested in horticulture attended. The report and balance-sheet were adopted, indicating a balance in hand of about £80. It was decided to hold the next show on August 11 and 12, in the Sophia Gardens. His Worship the Mayor is President of the Society; and Mr. W. C. PEACE, who has long been connected with the Society, becomes Chairman of the Committee for the second time. Mr. A. E. DIXON, of Penarth, was elected Vice-Chairman; and the Secretary, Mr. H. GILBERT, was re-elected. It was decided to add the word "County" to the Society's title.

SHROPSHIRE HORTICULTURAL SOCIETY.—The result of the last Floral Fête was announced at the annual meeting on Monday, Feb. 8, at Shirley; the Mayor in the chair. It appears the total receipts of the summer show were £1,300, and the expenses £3,100. Cash prizes to the amount of nearly £350 have been awarded during the year. After paying the expense of the spring show and sundry sums voted to special objects, a balance of £1,015 remains as the year's net profits, which in accordance with a decision announced in our columns will be expended in the erection of a statue of CHARLES DARWIN, the contract for which is £1,000 complete. The Royal Horticultural Society have joined this society in holding a great Commemorative Show in August next, when the prizes offered by the Shropshire Society will be greatly increased. Under the presidency of Sir THOMAS LAWRENCE, Bart., for the Royal Horticultural Society, and the Right Hon. Lord KENNON for the Shropshire Society, an exhibition of plants, flowers, fruit, and vegetables will be held on a scale perhaps not before exceeded in England.

HOWICK HALL GARDENS.—We understand that the vacancy which has arisen in the charge of these gardens, through the succession of Mr. D. 1891-5 to the management of the Duke of Gloucester's gardens at Drumlanrig Castle, will be filled by a member of the staff at Drumlanrig.

STOCK-TAKING: JANUARY.—The Board of Trade Returns for the first month of the year show an increase in the imports to the value of £1,501,812 or a total of £39,975,668. As will be seen by the accompanying extract from the summary table, the food supplies have fallen off in value—as, by the way, have various other subjects; whilst the quantity

of textile materials have gone up to a very considerable extent, cotton and wool figuring largely—wool to the extent of 25,000,000 lb. weight. Our usual extract is as follows:—

IMPORTS.	1896.	1897.	Difference.
	£	£	
Total value ..	38,473,856	39,975,668	+1,501,812
(A) Articles of food and drink, duty free.....	12,512,898	11,805,167	-707,731
(B) Articles of food and drink, dutiable ..	1,892,900	1,816,837	-76,063
Raw materials for textile manufac- tures	9,001,786	11,766,396	+2,765,210
Raw materials for sundry industries and manufactures ..	3,189,712	3,229,851	+40,139
(A) Miscellaneous articles	1,258,115	1,224,582	-33,533
(B) Parcel Post ..	122,666	120,375	-2,291

Respecting fruit imports, the following are useful figures:—

IMPORTS.	1896.	1897.	Difference.
fruits, raw:—			
Apples .. bushel.	293,168	289,991	-4,177
Cherries
Plums	210	-210
Pears	834	2,455	+1,624
Grapes	1,789	1,281	-508
Unencased	47,234	36,639	-10,686
Onions	697,934	494,254	-114,672
Potatoes cwt.	41,672	23,465	-18,207
Vegetables, raw, unen- cased	£8,347	£61,017	+52,670

This table shows more of the *minus* sign than it has for years past, which the "working day" less in the past month, as compared with the same period last year, does not quite account for. The

Exports for the month show a falling off amounting to the sum of £1,384,112 on a total of £19,762,378. Of course the five Sundays in the month have affected this great section of our commerce; perhaps the settlement of the new American Cabinet may lead to encourage speculation in textiles, and so do something towards balancing items in the next monthly returns.

WASTED ORCHARDS.—Our energetic contemporary, the *Gardener's Magazine*, has done good service by drawing attention to the miserable state into which the majority of our orchards have been allowed to fall. A short run out of London by any of the main lines of route will furnish plenty of illustrations of neglect and apathy. On the other hand, there is happily evidence that fruit culture is being taken up in earnest and in a business-like way, and hence we may look for the speedy abolition of the "wasted orchards," and their replacement by more practical plantations. This will have to be effected rather by the gardener (market-gardener, to be precise), than by the ordinary farmer, and the railway companies must do their share: some of them have indeed seen that it is their interest to aid in the development of the resources of the land, fruit included.

"GLASSY" APPLES.—Occasionally, and at rare intervals, correspondents send us Apples, a portion of which has a glazed, semi-transparent appearance. Hitherto no adequate explanation has been given of this singular change. But recently M. PAULIENX (*Bull. Bot. Soc., France*, November 27, 1896) has shown that it is due to a Bacterium which he has been able to isolate.

CULTIVATION OF CANNAS IN WATER.—Our readers will be interested to learn that astonishing results have been obtained by M. MOLIN, nurseryman at Lyons, by planting in spring the rhizomes of Cannas in baskets filled with soil, and sinking these to the rims in a vessel holding water, where upon the roots soon pass through the sides of the basket, and

originate an extraordinary luxuriant growth of leaves and flowers; especially fine, it is said, being the varieties Königin Charlotte and Madame Crozy.

APPLES FROM THE ANTIPODES.—Arrangements, we believe, are now completed for the transport of the Tasmanian Apple crop to the home markets. Both the P. & O. and the Orient lines will, as usual, do the work, and it is expected there will be nine cargoes in all. The first ship is the *Mascilia*, due April 20; followed by the *Orada*, *Oreac*, *Arcadia* (May 2); *Austral*, *Paranetta* (May 18); *Orinda*, *Bullerat* (June 1). About a week will intervene between each arrival, and these steamers are to carry about 100,000 cases in all. There will be some minor consignments from Australian ports; but, of course, Tasmania will send the bulk.

THE PUTNEY AND DISTRICT CHRYSANTHEMUM SOCIETY.—By way of marking the sixtieth year of Her Majesty's reign, the tradesmen of Putney and Wandsworth are this year, we understand, to offer a Silver Cup, value 25 guineas, to be called the Putney and Wandsworth Tradesmen's Commemorative Challenge Cup, also handsome money prizes, in an open class for cut blooms.

FRUIT FROM THE CAPE.—The first instalment of the season's fruit crop has arrived from the Cape in the steamer *Scot*, and has been sold. The consignment consisted of more than 400 boxes of Peaches, fine in quality, if not always large in size. Prices ranged from 6s. to 10s. per box of twenty. The lower price was for a consignment, part of which had got slightly bruised—possibly the perfection of packing has not yet been attained. The retail prices were from 9d. to 1s. each.

BERNARD VERLOT.—The death of this gentleman is announced in a recent number of the *Revue Horticole* (Feb. 1). Our first acquaintance with him was when he was connected with the Jardin des Plantes; subsequently he was a Professor in the National School of Horticulture at Versailles, whilst recently he superintended the trials made by Messrs. VILMORIN, ANDRIEU ET CIE, at Verrières, where we had the pleasure of seeing him last year. VERLOT was an excellent botanist, and his *Guide du Botaniste Herbieriste* is quoted in most of the textbooks.

"EVERYBODY'S GUIDE TO PHOTOGRAPHY."—This is one of the well-known "Everybody's" series, published by SAXON & CO. (Bouverie Street, Fleet Street, E.C.), and is truly described as being "a practical hand book, containing full instructions for amateur photographers, simply written, easily understood." It has the merit that it appeals to real beginners, and does not leave out even those first few easy steps which other authorities too often imagine are known to all men. This volume is small enough to be carried in the pocket, and as the information contained in it is not meant only for novices, may be recommended as a constant companion even for experienced photographers, who may ever and anon be glad to refer to it.

HOUSEHOLD INSECTS OF THE UNITED STATES.—The fourth *Bulletin* from the United States Department of Agriculture, Division of Entomology, is contributed by Messrs. L. O. HOWARD and C. L. MARLATT, and deals with the principal household insects of the United States. There is also a chapter by Mr. F. H. Chittenden on "Insects Affecting dry Vegetable Foods." It should prove a great convenience to housekeepers to be able to obtain such a reference-book as is this, wherein is brought together much information such as is usually only to be found scattered here and there in various publications. Not merely are the more common intruders mentioned, but they are carefully described and illustrated on an enlarged scale, that the identification of the species may be made easy. Various ways of eradicating insect-pests are mentioned, and being based upon observation and scientific principles rather than upon theory merely, are as reliable as is the other information contained in this book. Some of the remedies prescribed against large incursions of insects read somewhat whimsically, though

the matter, to those immediately concerned, is certainly serious enough. Thus, as a palliative measure against invasions of fleas in the McGraw Building of the Cornell University, we are gravely told how "Professor GAGE tied sheets of sticky fly paper, with the sticky side out, around the legs of the janitor of the building, who then for several hours walked up and down the floor of the infested room, with the result that all, or nearly all, of the fleas jumped on his ankles, as they will always do, and were caught by the fly-papers." To some housekeepers, to whom the presence of any insect is more or less objectionable, the following remedy will seem almost worse than the complaint. Certain premises "proved to be swarming with bed-bugs; but very shortly afterwards the little red house-ant discovered the presence of the bed-bugs, and came in enormous numbers, and Mr. PERCIVAL witnessed the very interesting and pleasing sight (!) of the bed-bugs being dismembered or carried away bodily by these very minute ants, many times smaller than the bugs which they were handling so successfully. . . . A correspondent goes so far as to heartily recommend the artificial introduction of the ants to abate this bug nuisance." A plan of thinning the too-abundant ranks of mosquitoes is described as being "particularly ingenious and pleasant." It is certainly rather elaborate—as first fly-traps are to be set, the victims falling to which are to be used for feeding small fish which are themselves held captive that (presumably when the supply of flies is short), they may make invasions on the mosquito larvae with which the water they dwell in is infested. A "quart of flies a day" and larvae *ad lib.* is certainly liberal diet, and says something for the quantity of insects to be coped with. The paper on insects affecting dry vegetable foods, and describing flour-beetles, meal-worms and moths, and grain-beetles, is rather calculated to spoil the appetite of a fastidious and hungry reader. No doubt a "worny ham need only be returned to the dealer from whom it was bought;" but vivid descriptions and illustrations of "horrors" enlarged to an almost alarming size may well make the too inquisitive reader regard even the ingredients of his favourite Christmas pudding with disfavour. We can only hope that he will be large-minded enough to overcome this prejudice; to learn first to wonder at, and in the end to admire his household insects, and to appeal to this really useful treatise when he wishes for fuller information about their nature and structure. The handbook also tells us, as has been said, how our little pests may be kept down when their excessive numbers renders such a course advisable.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—The monthly meeting of this body was held at the Guildhall, Newport, on Saturday, February 6, Dr. GROVES, B.A., J.P., presiding. A paper was read by Mr. H. J. JONES, Ryecroft Nurseries, Lewisham, on *Chrysanthemums*, which dealt with the entire course of cultivation of the queen of autumn plants from the cutting to the blooming stage. Many questions were asked, and answered by the lecturer. At the close of the lecture a collection in aid of the Gardeners' Benevolent and Orphan Funds was made. The next lecture will be given by Mr. W. TRIBBECK, F.R.H.S., on "Winter Vegetables." Several new members joined the Association.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.—At the eighth general ordinary meeting of the Session 1896-97, to be held at 8 P.M. on Monday next, the 15th inst., at the Institute, 9, Conduit Street, W., Mr. H. E. MILNER will read a paper upon "The Garden in Relation to the House." The paper discusses the style to be adopted, formal and natural, and deals in detail with the site, the approach, entrance and forecourt, shelter, soil, the terrace, and garden formation and planting. The author maintains that in the parts surrounding the house the architectural feeling of its design should be carried out, and that beyond these a broader treatment should prevail, and draw into the scheme the greater landscape. Considerable discussion is expected.

VINEYARDS IN FRANCE: PRODUCE FOR 1896.—Only twice in the last twenty years (1878 and 1893) has last year's wine-crop in France been exceeded; and this yield is placed at one thousand millions of gallons, or 230 gallons per acre. The produce of French vineyards in 1895 was but half that of its successor. But even vast as is this yield of wine, it is far from being sufficient for the requirements of the French people, for the imports have gone up from six million gallons in 1875 to something like 244 million gallons in 1890; and the official estimate that 200 million gallons will be required, notwithstanding the last great crop. Imports come from Algiers and Tunis in some profusion, but France is much indebted to the foreigner for its ordinary supply—Spain alone sending over the Pyrenees more than 100 million gallons a year. The export of wine from France—about 100 million gallons twenty years since—has kept falling off, until now they are represented by less than forty millions.

FRIEDRICH LESEMANN.—A well-known German gardener, formerly in the service of the Duke of BRUNSWICK, died on December 16, 1896, at the age of seventy-one years. The deceased was a Fellow of the Horticultural Society of Vienna, and belonged for a great number of years to the managing committee.

BUNYARD'S CENTENARY SHOW.—We are informed that from the proceeds of the show of fruits held by Messrs. GEO. BUNYARD & Co., Maidstone, in the autumn of last year to celebrate the centenary of the firm, cheques for five guineas have been sent to the Gardeners' Royal Benevolent Fund, the Royal Gardeners' Orphan Fund, and to the Church Institute at Maidstone respectively.

THE CRYSTAL PALACE.—Our readers are aware of the regrettable illness that has overtaken Mr. HEAVY, who has been Superintendent of the Garden Department at the Crystal Palace for many years. This has compelled Mr. HEAD to resign the position, and we understand that Mr. GEORGE CASKELTON has been appointed to succeed him in this responsible position.

NEW VARIETIES OF VIOLETS.—We have received from Mr. GEE-ON, of Cowdry Park Gardens, two bunches of beautiful Violets, under the names Victoria and California. The first-named, Mr. GEE-ON thinks, is the finer flower, and perhaps the finest Violet existing. Both have large flowers, and long, stout foot-stalks, which render them well suited for arranging in vases, or for use as cut and spray flowers, without the trouble of wiring them. The flowers were produced on plants growing in the open border, and protected at the sides by means of boards set on edge, and carrying frame-lights, no heat being employed. At night mats are usually thrown over the lights, supplemented with litter during severe frost.

PUBLICATIONS RECEIVED.—*Supplement to the Seed List of H. KLATT, 69, 79, Graefe Str., Berlin, concerning the pronunciation and spelling of the names of plants.*

BOOK NOTICE.

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES. RAPIDLY DO MESSRS. A. COGNIAUX and A. GOOSSENS push on their work of depicting and describing Orchids, as another batch of illustrations reaches us, and quite up to the standard of excellence displayed in former issues. The genus *Oncidium* is

commenced with *O. Forbesii*, *O. Lunceaum*, and its white-lipped variety *Louvreauxiana*, and the favourite "Butterfly Orchid," *Oncidium Papilio*. *Odontoglossums* are continued with *O. crispum virgineum* and *O. Pescatorei*; *Cattleya* with *C. maxima*, *C. Dowiana*, and *C. D. var. aureo-marmorata*. *Cypripediums*, *C. Curtisii* and *C. Leyceanaum* are given, the latter remarkably like the *C. × Lillian* Greenwood exhibited at a recent meeting of the Royal Horticultural Society. Of the genus *Lelia*, as well as of some of the others not already published in this work, the customary description and essential characters are given, the plates being *Lelia prastans*, which authorities in this country at least consider only a form of *Lelia pumila*, and *Lelia longipes*, Rehb. f., which, if the identification be correct, seems to be the plant known as *L. Lucasiana*, Rolfe, and in some gardens as *L. Crawshayana*. The only difference appears to be that in the plant figured as *L. longipes* the sepals and petals are nearly white, and not pale blue, as usually seen in *L. Lucasiana*. Possibly in the plant illustrated the surface colour had not developed, or had faded. The plant, the form of the flower, and the peculiar crimped yellow lip seems to be identical. Herein is seen the usefulness of these plates, as in this instance a species may find its way back to its prior name, or a very rare one be made known.

THE CANNA.

The recent introductions of this genus are becoming very popular, on account of their brilliant-coloured flowers, and the ease with which they are grown and stored when at rest. I employ many of the fine varieties for massing in the gardens and for sub-tropical beds, they are now almost indispensable. When the more recent varieties recover from the weakness caused by mutilation for propagating purposes, I am of the opinion that we shall see such elegant types as *C. Austria* and *C. Italia*, freely used in out-of-doors gardening. The present is a suitable time to prepare the plants which are intended to be planted out, as while the potting for general purposes takes place, the varieties for massing may also be dealt with. The roots may be divided, and the shifting-on principle may here be advantageously set aside by affording them sufficiently large pots at the first, so that the entire season may be gone through without re-potting, and any liquid-manure during the rest.

The bulk of the potting compost may consist of sound fibrous loam, decayed horse-droppings, sand, and wood-ashes, with a dusting of Thomson's Vine and Plant Manure. Do not afford any water for some time after re-potting the rhizomes, and afford a mild bottom-heat if possible, for although this is not essential, it is a ready means of getting small pieces established rapidly. Beside those already named, there are *C. L. E. Rally*, *C. Kingin*, *Charlotte*, *C. Kaiser Wilhelm*, *C. Antoine Barton*, *C. Charles Henderson*, *C. Florence Vaughan*, *C. Star of '91*, *C. The Garden*, and *C. Sophie Buchner*. I grow a great many more varieties than the foregoing, but these comprise the best of them. *J. F. McLeod.*

BARON SIR FERDINAND VON MUELLER.

The following extract will be read with interest, as supplementing what has already been published concerning this indefatigable naturalist:—

He was a man below the middle height, not robust, but evidently possessed of a good constitution, otherwise he could never have set the laws of health at defiance as he did, and have lived to be threescore and ten years. Everything in the way of personal comfort had to give way to the cause of science.

He seemed to be always ready for a chat, a good long chat, in fact a conference, and the wonder to me always was when he found time for his work. I have been closeted with him for two or three hours at a stretch, and I repeated apologies on my part for taking up so much of his time were unheeded. All that one had to do was to listen. His power to speak for each

a long stretch surely indicated sound lungs, but both of his parents died of consumption before he was twenty-one, and he believed he inherited weakness of this kind. In consequence, be the weather warm or cold, he used to wear an Angora comforter round his neck, and on chilly or foggy days to make one end of the comforter a respirator. He used to dress in black, and usually his feet were enveloped in wooden shoes (sabots). He was far too much devoted to his life-work to spend more time or money than was unavoidable over his dress, and, as he never had a wife to take him in hand, he did not dress fashionably. The only finery he allowed himself to wear were his orders and some of his medals, which he donned on special occasions. He could make a display of these that no governor, politician, or scientific man in Australia could rival, and they seemed to give him

should die in harness. . . . His illness lasted only a fortnight, and for the first week he would insist on getting up and going into his office, though only for a short time. His death was, no doubt, due to an affection of the brain, brought on by constant study, worry, and insomnia, to which might be added, almost a total want of bodily exercise. He passed away (October 10) quite peacefully, without any apparent pain."

Bailey of Brisbane, Guilfoyle of Melbourne, and the writer, took steps (which we were able to carry out through Mr. Guilfoyle's kindness), to place on his mortal remains wreaths composed of flowers indigenous to our respective colonies, and so, embowered amongst the Australian spring-time flowers he loved so well we let him rest. *Agricultural Gazette of New South Wales.*

must be warmed to 80°, and it should consist of rich turfy loam, leaf-mould, and a small quantity of decayed horse-droppings, with a considerable quantity of silver-sand. Grow them in a very warm, moist house, affording water in abundance, and syringing them twice or thrice a day. No trouble should be spared to keep the plants free from red-spider and Thrips, which, if allowed to infest the foliage, soon render them unsightly objects. Nothing is so inimical to these pests as abundant syringing, and dipping the plants overhead in a mixture of black-soap with a teaspoonful of petroleum to every 4 gallons of water. This is a capital insecticide for Thrips, killing the insects and their eggs. If a plant becomes badly infested with red-spider, sponge the leaves with soap-suds. As these plants are very easily injured even in summer by being taken from the

FIG. 31.—COUNCIL-ROOM OF THE ROYAL HORTICULTURAL SOCIETY, AND HOME OF THE LINDLEY LIBRARY, 117, VICTORIA STREET, WESTMINSTER, S.W. (SEE LEADING ARTICLE, P. 108.)

pleasure. This was a little vanity (I certainly do not use the word in an unkind sense) that sometimes amused onlookers, and no one would begrudge him the pleasure they gave him.

The Baron always spoke with a strong German accent, and he had a kindly, conciliatory way of speaking. His literary style was quaint and peculiar; he loved long, often involved sentences, and long words, often of his own coining. His English often lacked the structure of that language, but his sentences were usually well worth paraphrasing. One little peculiarity was his epistolary style. The "Dear Mr. So-and-So" would never begin the letter as is customary, but it would be found later on, after an introductory paragraph or two. One of his characteristics certainly was quaintness, of which one could readily give a number of additional instances.

I cannot do better than quote from a letter from Mr. J. G. Luchmann, for many years the Baron's right hand in his botanical work. "The Baron had, at least, his one great wish fulfilled, namely, that he

CULTURAL MEMORANDA.

COLLEUMS (CROTONS).

These exceedingly beautiful and useful plants, if wanted when small for decorative purposes, should be struck from cuttings put in at intervals of two or three months, the cuttings being placed singly in small pots arranged in groups, and covered with large bell-glasses. If the bottom-heat is kept steady at 55°, and the air moist, roots soon form, and the lower leaves are retained on the cuttings. When it is ascertained that the cuttings have roots, air should be admitted to them by tilting the bell-glasses, gradually affording more air till the plants can bear full exposure without flagging. As the uses to which *Colleiums* are put in the dwelling cause them to lose the leaves at the bottom of the stem, those plants which have grown higher than 1½ foot may be topped, and the tops made use of for cuttings. When potting *Colleiums* at the present season, the compost

stove, any which are to go to the conservatory or greenhouse at that season should be gradually inured to a lower degree of heat. This also holds good of plants going to exhibition or into the dwelling. Beyond pinching the tips of the shoots to give bushiness, the plants require but little help, as their growth is naturally bushy and regular. In order to bring out the rich markings of the leaves, the plants must be afforded sunlight in abundance at all times. Our *Colleium* house is kept in the winter at 60° to 70°, according to the state of the weather. *J. H. C. S., Cheshire.*

TREES AND SHRUBS.

THUYA ORIENTALIS FALCATA.

Some of the many forms of the Chinese arbor vitae are by no means readily identified, but such will not apply to the subject of this note, for the curiously shaped cones render recognition both speedy and

certain. The partially-upright habit, too, might go far in determining the variety, but without fruit such means of identification would be hazardous, so many partaking of the dense, conical habit of the shrub in question. The large deep-green cones, of very irregular shape, and with the scales terminating in long-hooked points, resembling the fangs of a tooth, are different to those of any other member of the species. Each cone is fully three-quarters of an inch long, and composed of six scales and six seeds, two to each of the lower scales being the usual arrangement. The seeds are wingless, and weightier than those of any other of the *Thuyas*—31,500 going to make up a pound weight; while in *T. occidentalis* and *T. gigantea* the figures are 186,666 and 94,000. These figures are the average of four trials of each, with freshly-collected cones.

T. orientalis filicata is an excellent churchyard shrub, but for garden purposes it is too harsh, formal and stiff; and when old, it falls apart, being then top-heavy. *A. D. Webster.*

QUERCUS COCCINEA.

This splendid species of scarlet oak, a native of the Eastern United States from Pennsylvania to Georgia, is at the present time being much planted there as a street and road tree. The tree grows to a height of 70 to 80 feet, has dark-coloured (not yellow) bark; leaves egg-shaped in general outline, but divided featherwise, with three deeply cleft divisions on each side—shining, smooth, dark green above, and beneath of a paler hue. The foliage changes in the autumn to scarlet, or to a more or less orange-scarlet. This species would make a superb street tree for our less smoky towns, and for country roads near towns anywhere. We are surprised that it has not been, as yet, taken up by the trade, and recommended for this kind of planting. Seed should not be difficult to obtain.

HOME CORRESPONDENCE.

REMOVAL OF LARGE TREES.—I enclose a photograph of a fine Purple Beech, which we moved last November for Mr. Wilson, The Hermitage, Holmes Chapel, near Crewe. The tree was on a terrace close to the angle of an additional wing, which has been added to the house, and unfortunately both roots and branches had been cut to a considerable extent to make room for the foundations and in the erection of the building. The tree was moved some 50 yards, and partially turned round in the operation. The dimensions of the tree are as follows:—Girth at ground, 9 feet 2 inches; girth at 4 feet from ground, 6 feet 3 inches; height, 40 feet; diameter of branches, 62 feet. I estimate the total weight moved at 30 tons. We moved two very large trees, a Lino and a Horse-Chestnut, in May, 1895, at Worsley Park, for the Bridgewater Trustees. The Chestnut, which was the heavier tree of the two, was taken up an incline of at least one in six. Both trees were in growth, and I hear they have done well. At the time the Buckland Yew was moved by my late father in February, 1880, various opinions were expressed as to the ultimate result of the removal. Such of your readers as remember the correspondence will be interested to read a letter we have received from Rev. Taberville Evans, vicar of Buckland, Doyce, in December last.

"Buckland Vicarage, Doyce, Dec. 10, 1896.
"Dear Sirs.—My conscience smites me. I believe you were good enough to ask after the Yew a year ago, and I then promised to take a photograph of it in the spring, and send you a copy, and I now know I have not done so. I will try and remember to do so when the tree is in blossom, and meanwhile I will send a photograph I took of a portion of it in May or June last. I am happy to tell you that it is in splendid condition, and improving every year. There is no doubt your good father's skill, and the intense interest he took in the work, have added many years, perhaps centuries, to its life.—Yours faithfully,
"TUBERVILLE EVANS."

At the present time we are preparing to move an Oak of considerable size at Copped Hall, Epping, the dimensions of which are as follows:—Girth at ground, 10 feet 2 inches; girth 4 feet from ground, 6 feet 6 inches; height, 46 feet; diameter of branches, 45 feet. If any of your readers would like to witness the operation, I shall be pleased to inform them privately on which day the tree will be moved. *John Barrow, Elston Nurseries, Barnumsh, Derby.*

BULBS FROM CHITRAL.—Mr. Duthie very kindly sent me last summer a supply of corns labelled "White Crocus, Chitral." Several of these have now flowered, some in the open; but the flowers are yellow, not white, and have been diagnosed at Kew as *C. Korolkowii*. It is, of course, possible that some of the corns which did not flower this year may throw up white flowers next; but this seems unlikely, since the foliage of all is alike. My hopes of a new species are therefore dashed; still, it is interesting to have a new habitat for this so common flower. A few corns had been sent me in 1895, but none of these really flourished. With them were a few Tulip bulbs, which did not flower last summer. These, however, could not have been of the same kind as those mentioned in the *Gardener's Chronicle* a few weeks back, for they were simply *T. Clusiana*, though varying a little from the type in the depth and sharpness in outline of the purple blotch. *M. Foster.*

THE DAWN OF REASON IN A FUNGUS.—One of the subjects in which I am interested is the Dawn of Reason in animals. Seeing an essay advertised under the name of "The Dawn of Reason," by James Weir, Jun., M.D., in *Medical Reprints* for December 15, 1896, I purchased the number. To my surprise, I found that Dr. Weir had detected in the yellowish fungus, well known to gardeners as the "flowers-of-tan," and to botanists as *Ethaliium septicum*, not only vision, necessitating an eye and a brain, but "memory and conscious determination." I have read wonderfully different things about the Mycetozoa, to which this organism belongs; but nothing so startling as this from the pen of a professional man. Before quoting from Dr. Weir, it should be said that some students of biology claim the *Ethaliium* for the animal kingdom, whilst others make an equally strong claim for the vegetable. It does not matter a straw how the difficulty is settled; but *Ethaliium* and like organisms are preserved in the Department of Botany at the British Museum, and in the Herbarium at Kew. They do not keep them at the Zoological Gardens. Dr. Weir says:—"The natural habitat or dwelling place of *Ethaliium* a minute, microscopic animalcule of very low organisation, is sawdust." "Minute microscopic animalcule" is good—the fact is, this fungus is sometimes 1 foot across, and 1 inch or more thick. It certainly sometimes grows on sawdust, but it is very common on tan, on rotten wood, on tree stumps, and various other things. "If these creatures," says the Doctor, "be taken from the sawdust and placed in a watch-glass in which there is water, they will confine themselves to it; but if the glass be placed on sawdust they will leave it, crawling over its sides in order to get into its congenial surroundings the sawdust. This shows conclusively," continues Dr. Weir, "that they recognise the dust through the transparent glass, and that they also remember and regard it as a more desirable home." Evolutionists would do well to discard Amphioxus at once, and see if they can trace the origin of man to *Ethaliium*. Unfortunately, Dr. Weir has not told us whether he was able to detect a rudimentary back-bone in this "creature" whilst it was looking through a watch-glass. In conclusion the doctor says, "Memory, conscious determination, and the fundamental principles of reason are in this instance clearly demonstrated." It is hardly necessary to comment on this; and there is a great deal more of the same stamp in the article referred to. It is to be hoped that the daily press will not get hold of it, or something even more startling may see the light in "leaders" and columns of "scientific news." *W. G. S.*

"UNFAIR TRADING."—The best thanks of the trade are due to you for publishing, and to "Local Florist" for writing, his able article in last week's *Gardener's Chronicle*, on this important subject, which I trust will be the means of exposing, if not eradicating, this unfair system of trading. Another class of unfair trading is that practised by many noblemen and gentlemen throughout the country of sending to market choice fruits, Tomatos, Cucumbers, flowers, &c., which in many instances have been expressly grown for that purpose, to be sold wholesale in competition with those who earn their living solely by marketing these goods, but who cannot possibly compete with their richer rivals, inasmuch as the latter are contented if their sales assist in reducing the wages' account of the garden; whereas the other has no other means of support for his family and himself, and is too often at his wits' end to know how to make ends meet—and sometimes this unfair trading spells to them ruin. Surely these gentlemen market gardeners cannot have thought of the unfair

way they are competing with the working-man market-gardener, or I feel sure some of them at least would discontinue this unfair practice. *Justice.*

PENRHYN CASTLE GARDENS 40 YEARS AGO.

—As an old Penrhyn man I was glad to observe its reputation for good gardening supported by the testimony of Mr. Crump in a recent issue of the *Gardener's Chronicle*. Forty years have sped since I worked in these gardens, and in those days I have heard competent judges say that the keeping of the gardens at Penrhyn was equal to anything in Great Britain, praise which is well merited at the present time. It was during my stay that the Queen and Prince Albert were entertained at Penrhyn Castle for nearly a week, together with a number of Ministers of State. On this occasion the sides of the carriage drives were lined with thousands of villagers and quarry-men to greet Her Majesty and her consort, and choirs of Welsh singers from Bethesda, who attended the Castle Chapel and sang to her Majesty's delight; memorial trees were planted, the oldest men employed in the gardens assisting. In those days the Grapes that were grown at Penrhyn were fair, but they would not quite reach Mr. Crump's high standard of excellence. Pine-apples were well done, and Mr. Burns was much pleased with a gold medal awarded him by one of the London societies for a number of the Queen Pines weighing over 5 lb. each, which he sent to an exhibitor. The espalier Pear-trees at that time were some of the best in the kingdom, and I recollect on one occasion we exhibited at Bangor show a dish of White Brunswick Figs from a south wall, and every fruit weighed fully 8 oz. *R. M. Newbury.*

BEURRÉ DIEL PEAR.—This variety is usually classed as being in season in November and December; with me, however, it has kept this year till February 8, and I was enabled to send in a dish for dessert on that day. I may say that the fruits were gathered early in October, from some aged trees growing on a wall, and no particular pains were taken to ensure good keeping, the fruits being kept in a cool, unheated room. *J. Voss, Killeston Hall Gardens, Derby.*

PARENTAGE OF ROSES.—I find that in an article entitled "A Manse Garden," contributed to vol. ix. of *Amateur Gardening* (p. 354), which appeared many years ago, I have spoken incidentally of Etienne Levat as being the parent of Duke of Fife. So far as I am concerned, the derivation of the Scottish Duke is a matter of small importance, as this Rose has never been successful in my garden. I am much more concerned of the Duchess of York and Duchess of Fife. *David R. Williamson.*

RORIDULA GORGONIAS.—Mr. Moore states in his note in your last issue, p. 96, that this plant flowered at Edinburgh and Dublin in December of last year. Our plants showed for flower in November, and if the plants in Dublin have behaved like those at Edinburgh, your correspondent will bear me out, when I say that the buds are very slow in expanding, and when they do open, only one, or perhaps two, expand together. The first flowers on our plant opened early in December. My note of the flowering of this species in the *Gardener's Chronicle*—sent really on January 11—was kept back in order that a photograph, showing the inflorescence fairly developed, might accompany it. The plants that first flowered here had all white flowers. Some that are now coming into flower show a pink colour, and we have also some plants with partly pink and partly white blooms. Whether this variation is due to the different conditions under which the individual plants have been grown here, is a point about which I may be able to say something at a later period. *R. L. Hervey.*

ADIANTUM CAPILLUS VENERIS, VAR. SEMILANATUM.

—Some years ago, when staying in the west of Co. Clare at the village of Lisdoonvarna, noted for its sulphur and iron spas, I collected plants of an *Adiantum* growing in the deep and narrow clefts of a large plateau of water-worn limestone-rocks within view of the Atlantic Ocean. So rare were these clefts in the rock, that when lying on my side with downstretched arm I could only here and there reach to a plant. I have kept and grown it ever since, and recently specimens submitted to Mr. Baker at the Herbarium, Kew, have been determined by him to be the variety known as *semilatum* (Lowe), and he suggests that the fact should be put on record. The fronds were remarkably long, and bearing distinct and large bold pinnales. It may be of interest to Fern-growers to learn that this Fern has been collected in Ireland. *J. T. Bennett-Poe, Chesham.*

CEORUS DEODARA AND C. LIBANI.—There having been various articles upon this subject in your pages, venture to send you a few measurements which I made of three of the healthiest specimens of Cedar of Lebanon growing in this country. They are three entirely distinct varieties, and the measurements were taken on June 1, 1895. The first specimen has a height of 100 feet, girth of stem 2 feet from the ground of 17 feet, circumference of branches 225 feet. This specimen has foliage of a dull green colour, and branches that stretch out horizontally; the cones are a little more conical than specimen No. 2, and a trifle larger. Specimen No. 2 has a height of 110 feet, girth of stem 2 feet from the ground of 21 feet, circumference of branches 285 feet. This tree has foliage of a very velvety-green colour, and very short thick needles, and bears cones in great profusion, which are shorter and rounder than the preceding variety. The third specimen has a height of 100 feet, a girth of stem 2 feet from the ground of 17 feet, circumference of branches 285 feet. This tree is the most graceful and elegant of the three. The foliage is of a very light grey colour, and forms a fine contrast to the other two. The yield of cones is nearly so freely, and these are of a light greenish colour, and much more conical than either of the others. All three yield a great profusion of male catkins. I may mention that the three specimens are in a row, the largest specimen in the middle, in front of the residence on a sloping lawn, and they have ample space around them. In the winter of 1896 I felled a very good specimen of *Cupressus macrocarpa*, which had been partially killed by the sharp weather of 1895; it was 69 feet high. The wood of this species is of a lighter shade, being very soft. *M. E. Mally, Coombe House Gardens, Brighton.*

GRAPES GROS MAROC AND OTHERS.—In regard to varieties of Grapes shown at Edinburgh last September, I am glad to notice that the subject has been brought to the notice of gardeners in general. It is a notorious fact that Gros Maroc, Alwicks Seedling, and Black Alicante Grapes had preference on this occasion to such fine varieties as Muscat Hamburg, Madresfield Court, and Muscat of Alexandria, and I am able to endorse everything Mr. Ardrie wrote on p. 83 of the *Gardeners' Chronicle* for Jan. 30. I have exhibited Grapes at the Edinburgh shows for many years with more or less success, and at the last September show I had no reason to be dissatisfied with the judges' fact, but I am bound to say that I never attended any show where more adverse criticism on the decisions of the judges was to be heard, especially in the larger classes; and everybody seemed astonished when the awards were made known. I agree with Mr. Divers (see *Gardeners' Chronicle*, p. 96), that Mrs. Pince, Madresfield Court, Muscat and Muscat Hamburg are sometimes shown in poor condition, and had this been the case at Edinburgh, there would have been little or no comment, but the reverse was the case; and it was in face of the fine quality of these varieties, in size of bunch, berry, and finish that the awards caused wide-spread dissatisfaction, amongst exhibitors and non-exhibitors alike. It is, I think, high time that something should be done in the way of classification of Grapes at the Edinburgh shows, and others at important centres north of the Tweed. *Hugh Thomas.*

— I see Mr. Divers classes this Grape as one that is very easy to grow; with me, however, it is very difficult, in fact I can do no good with it. I have tried various ways, such as syringing when in bloom, fertilising with Black Hamburg pollen, &c., but still the bunches, which are large for this variety, consist of mostly stoned berries. The Vine is in a late house containing several varieties, an inside border, and growth is very strong. The flavour of the berries which came to perfection is very good. I am constrained to ask if there are two varieties of this Grape, as those I often see exhibited have rounder berries, and denser bloom than those I have here, which have oval berries of a deep plum colour, when the bloom is removed. My late employer pronounced the flavour first-rate, but did not like Gros Colman, Alwicks Seedling, or Alicante. In my opinion, the former Grape always has an earthy flavour till it has been cut from the Vine for upwards of a month. In regard to the question of the relative value of Grapes on the exhibition table, now being discussed in these pages, I have been an exhibitor for many years, and think judges, as a rule, lean too much towards size and appearance. If they would just ask themselves this question, "Would my employer eat these Grapes at this time of the year?" their award would often be different. It is monstrous to observe at shows held in July and

August, Gros Maroc, Gros Colman, or Alicante, &c., while there are plenty of Black Hamburgs, Madresfield Court and other fine-flavoured Grapes to compete with. After the middle of September we expect to see late Grapes on the exhibition table, and then size and appearance should have due weight, when accompanying quality. Personally I would place the Black Hamburg as far in front of other black Grapes as the Muscat of Alexandria is placed in advance of the white varieties, but we often see it placed second to other kinds, of finer appearance in mixed classes. *John Wilkes, The Gardens, Grosvenor Hall, Stafford.*

— After many years experience in cultivating the Grapes-vine, I come to the conclusion that outside borders soon become inert masses of soil, with a temperature that is so low to stand late early and quick root action, hence shanking; and I believe that most of the fine Grapes we see at exhibitions are grown on borders made inside the vineries. The Gros Colmar Vines at The Hayes are planted in its inside borders, and being started early in January, they are afforded a long season in which to mature the fruit, little air at the top and bottom being afforded all through the forcing season. When the fruit commences to colour, more air is given than heretofore, and water is freely applied at the root with plenty of artificial and sun heat. In reference to the size of the borders here, I may inform "Cicestrian" we have a viney planted with Vines of Muscat of Alexandria at 5 feet apart in an inside border that is 4 feet wide by 2 feet 4 inches deep, with two rows of 4 inch hot-water pipes underneath. These Vines are pruned on the spur system, as are all our Vines, and they have carried good crops of fruit for the last 15 years. I attribute my success to a warm border and an abundance of water. For many years they have been started early in the month of February, watered at intervals of three weeks to the beginning of May, weekly to the end of September, the quantity being gradually reduced as winter approaches. The top soil is removed annually, and a layer of freshly-cut turf laid on the roots, together with a good dressing of cow-dung, a finish being put to the whole with very fine soil. The variety Lady Downes' in a border of the same size, eight years planted, and started six weeks later, is doing equally well. Should "Cicestrian" contemplate planting, I would advise him to try inside borders for Grapes ripening at all seasons. I well know that the orthodox size of Vines border is about 6 feet, and the measurements of those we have here, yet "Cicestrian" may with proper attention to details produce good Grapes in borders of such dimensions as above stated. *John Bates, Stone.*

— Would Mr. Ardrie kindly tell us why he did not write sooner about the judging of Grapes at Edinburgh in September, 1896? I must say that I am surprised at his boldness in endeavouring at this date to challenge the decision of the judges at that Show, and still more at his audacity in stating that "the same thing occurred in the four-bunch class; in fact, it would seem that quality was not recognised, as the coarsest and most ugly shaped bunches of the coarsest varieties were those which had the preference." And then adds, "What do northern gardeners think of that?" Being a northern gardener, I think that statements such as the above are, to put it mildly, very misleading, and have very little, if anything, to do with the "merits and demerits of Gros Maroc Grapes." In my opinion such statements are more like the pent-up growl of a disappointed exhibitor than of a Scottish gardener who is anxious to find the position Gros Maroc should take in a competition with other Grapes. I have to ask Mr. Ardrie to prove wherein his statements of coarseness and ugliness apply to any of the bunches staged, either in the lot for Six or less than three varieties, that gained 1st prize, or the "Four or less than four varieties" which gained 1st prize? Mr. Ardrie says that he "noticed at the same show that the judges preferred the flavour of Black Hamburg to that of Muscat Hamburg." Perhaps the judges took notice of a footnote in the schedule referring to that class, which says, "These bunches must weigh not less than 1 lb. each." Mr. Ardrie asks who is to blame for driving out the grand Grapes from our exhibitions, and straightway blames the judges; making out himself that the "grand Grapes" were there, but that the judges ignored them. I feel sure that the judges selected by the Royal Caledonian Society are gentlemen who will not pass over or ignore "grand Grapes" in favour of the so-called "coarser varieties," all cultural points being equal. *A Northern Gardener.*

GARDENERS' ORPHAN FUND.—Would not the celebration of the Queen's Diamond Jubilee be a most

fitting opportunity to bring before Her Gracious Majesty the splendid work of the Fund instituted as a commemoration of her Jubilee in 1837? The loyal, and still very responsible, step taken in placing thirteen candidates on the Fund this year without election, to commemorate the sixty years' reign, would, I feel confident, practically appeal to the proverbial womanly and tender heart of the Queen, on behalf of a class of her subjects who, by their very helplessness and noblest circumstances, bring out all that is highest and best in the characters of those in high places, tending, in the recent language of the Prince of Wales, to brighten the lives and ameliorate the condition of Her Majesty's poorer subjects. I observe in the same notice which gives the gratifying intelligence as to the free election of the thirteen candidates, that the annual dinner will take place at the Hotel Cecil on April 14, under the presidency of Sir John Whitaker Ellis, Bart.—a good step in its way, and one, no doubt, that will be a financial success. The very cost, however, of attendance at such a function must of necessity absolutely shut out what may be called the purely gardening element from participating in this feast of reason and flow of soul in connection with their own Fund and a social grand opportunity is thus lost to the keeping in touch with all classes of the gardening community. Why not have a reasonably priced supper on the day of the forthcoming annual meeting of the Fund in February, and cordially invite subscribers to the business of the day, which would give those able to attend an increased interest in its working and support, and if the supper idea be carried out, a very enjoyable opportunity of exchanging mutual congratulations [A dinner, costing 5s. per head, is arranged to take place on Friday, Feb. 19, at Anderson's Hotel, Fleet Street, at 6 p.m. E.P.] which would be the first the Fund is not supported as it should be by the craft. Can such a state of affairs be wondered at? If one may so express it, the Fund wants democratising. Look through the subscribers' list, and see how very small a proportion of journeyman gardeners are represented in it, just the very class that should support it, in view of future eventualities. The growth of gardeners' mutual improvement associations and similar institutions is a very healthy sign of the horticultural times. Could not the aims and objects of the Fund be broadened by the numbers of young men attending such, that they may be induced to become subscribers? It may be said that to many of these the Fund would not specially appeal. True, but the object is such a good one, and the subscription is so small (only about one penny per week!) that the cry of the orphaned ones would not, I am sure, pass unheeded by those who are to represent the gardeners of the future, if the claims of the Fund upon all connected with the art of gardening were properly placed before them. *Life Member.*

HORTICULTURE: PAST AND FUTURE.—How much we all know respecting the condition of horticulture to-day! What it has been in the past those who are old, or have access to early gardening publications, can tell fairly well; as to what horticulture is to be in the future, we have no knowledge beyond what is furnished through the capacity of comparing what it was fifty years ago with what it is now, and reasoning by analogy accordingly. I have been led in this train of thought through having been permitted to handle glass cases containing the original publications of diverse kinds, some half a century old, and having a lively recollection of what gardening was in those far-off days, also cannot now help wondering what it will be half a century hence. Undoubtedly we have advanced marvellously, and gardeners to-day have at their disposal a wealth of material, of which their fathers did not dream; with that material have come also much heavier responsibilities and duties. We have but to turn to the Chrysanthemum, for instance, for an example, whilst in other directions (orchids, Roses, hardy plants, florists' flowers, and domestic floral decorations), show how the gardener's duties and labours have developed. We must not forget, however, that for all this wonderful expansion, whilst we are greatly indebted to trade enterprise, to native energy, to great wealth, and to the agency of the press, yet to nothing do we owe more than to the removal of the heavy duty that once existed on glass, thus enabling vast numbers of glass-houses to be erected cheaply, and to the introduction of the system of heating them by hot-water, a method that sold itself, even against all other methods. Still, the next great operating agent may be found in electricity. That is, no doubt, a marvellous force, and may yet work wonders for horticulture. *A. D.*

AN OLD ALBUM OF FLORAL DRAWINGS.

In the department of prints and drawings in the British Museum, there is preserved an album of floral drawings upon vellum, made by an artist named Holtzbocker in 1660. The drawings represent almost exclusively florists' flowers of about 240 years ago; and as every illustration is most minutely and elaborately finished in colour in the style of a miniature, the pictures give a very good idea indeed of what our forefathers' garden flowers were between two and three hundred years ago. The drawings are a little plain and formal, and often a trifle out of perspective, and sometimes bracts and other little details are left out. There is also the too frequent tendency to make all the blooms and leaves face the spectator with nothing behind, but notwithstanding these slight defects, the examples have obviously been taken direct from Nature with painful care. The drawings resemble in style and minute finish those of the brothers Bauer in the British Museum of Natural History, Cromwell Road; they, however, do not quite come up to the standard of the Bauers' work. The pictures are in body-colour, so that they somewhat resemble minutely-finished work in oil. No sections, or floral enlarged details are given, the object of the drawings clearly being to give striking and highly finished representations of popular garden flowers. None of the drawings have names attached, but they are numbered, and the numbers are referred to in a full index. The latter has, in some instances, curious spelling, as *Scapiosa*, *Pokabunda*, *Blatturia*, &c. In turning the drawings over, one is at once struck with the extraordinary advances made by florists upon the flowers to which they have specially turned their attention; whilst certain other plants, as *Jasminum*, the *Orange*, and such-like, remain now precisely where they were in 1660.

Amongst the first illustrations are *Aconites*, *Anemones*, double *Scillas*, *Hyacinths*, *Fritillarias*, and *Crowa-Imperials*; one of the latter is a very curious fasciated example. There are many *Tulips*; all these are small, and very interesting—the largest, only 2½ inches in extreme length of petal, is named "Goliath." Under *Ranunculus* many double forms are given, and one red *Ranunculus* is prolific. One variety has rose-coloured petals, which form the disc, with blue guard-petals. *Pionies* are well represented, but the blooms are all very small, the largest only 2½ inches in diameter. The *Gladioli* is well represented, but the spikes only carry from four to six flowers, and the largest bloom is only 1½ inch across when expanded. The difference between garden *Gladioli* of then and now is astonishing. A double *Solomon's Seal* is illustrated, and the common *Snowflake* with blooms very small. The *Bee and Fly Orchises* are given; these were just the same in 1660 as now. Next come *Lilies*, all very small, a typical bloom is 1½ inch in diameter. A prolific and very double *Colchicum* is given. Of *Cyclamens*, the largest blooms are only ½ inch across; but *Violets* were then as now, if we except the few forms to which florists have given attention. The *Polyanthus* has improved but little; they are now a little larger, certainly. No gold-edged form is given. *Primroses* are illustrated in considerable variety of colour, with the *Hose-in-Hose* and other forms. *Ophrys* and *Cypripedium calceolus* are the same as now, the latter is

named in the index *Cypripedium calceola-maria*, the last word being only understood in modern nomenclature. Sweet Peas are exceedingly small; the *Columbine* much as now, but a little less in size. The drawings of (*convolvuli* are failures. Poppies are well illustrated, and the fringed forms given, but the largest bloom is under 2½ inches in diameter. The *Scabious* is much as now. One remarkably prolific example is illustrated with five flower stems and foliage starting from the centre of the disc. *Lupinus* are very small, the longest spikes of bloom being under 3 inches. The drawings of *Centaureas* are failures. *Passion-flowers* are poorly done, with the bracts, &c., omitted. Drawings of *Canna* are given, but the spikes are only 3 and 3½ inches high. The common garden *Antirrhinum* is represented with small blooms, and with only from four to five flowers on a stem. A very double yellow *Crocus* is given, with eighteen petals visible on the side view. Strange to say, the *Carnations* are almost as large as now; whilst the heads of blooms in the Sweet William only measure 2½ inches across in the largest examples. *Larkspurs* are very small, blooms only 1 inch in diameter; and *Hollyhocks* only carry from six to nine small blooms. A great number of roses are illustrated, single and double, but the largest blooms are only a little over 2 inches in diameter.

The drawings vary greatly in quality; a deep purple *Allium* is a singular and hopeless failure. The drawings appear to represent all examples as life-size; this seems proved by the foliage, and by many plants being shown as exactly the same in size as they are now.

It will be seen from the remarks here printed that this album is well worthy of close study, not as an artistic production for imitation, but as a record of what gardeners have done for certain garden flowers in about 240 years. Every illustration of some sections, as in the *Roses*, is highly instructive; and it is not improvable that some varieties of garden flowers, as illustrated in this album, no longer exist in our gardens, whilst it is clear that some florists' "novelties" of recent years were well known to the continental florists of 1660—but to name some of these forms with certainty would take time, and involve a comparison of modern forms with the ancient. These remarks refer to *Roses*, and bulbous and herbaceous plants alike. *W. G. S.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 9.—The Committees of this Society met at the Drill Hall, James Street, Westminster, on Tuesday last, being the second occasion since the beginning of the new year. In anticipation, perhaps, of the Annual General Meeting (see p. 108), which took place in the afternoon, there was a large attendance of the members of committees and of fellow generally. The display was again a most successful one, and there was no lack of interesting exhibits. Apart from the *Oreliads*, of which there was a good show, the most extensive exhibit was one of various strains of *Chinese Primroses* from Messrs. CANNELL of Swanley. It almost covered the whole of one of the long centre tables. *Cyclamens* were again exhibited, one of the collection being from the nurseries of Messrs. H. Low & Co., and another from the establishment of Mr. CHAS. TURNER. Collections of miscellaneous plants and of forced flowers were shown in several instances, and a few of the earliest hybrid bulbous plants were exhibited in pots by several nurserymen, and a collection of *Daffodils* by an amateur. First-class Certificates were awarded to *Iris Bakeriana* and *Lepagaria rosea*, *Warham Court* variety; and a *Violet* named *Amiral Avellan* was recommended an Award of Merit.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), H. B. May, Chas. T. Dreury, R. Dean, J. H. Pitt, Robt. Owen, George Stevens, F. J. McLeod, R. B. Lowe, C. J. Sailer, J. Jennings, H. J. Jones, H. J. Cutbush, Thos. Peck, Chas. Jeffries, R. M. Hoar, W. Hain, J. D. Pinder, Chas. E. Pearson, Chas. E. Shea, Chas. Blick, H. Turner, Geo. Paul, J. W. Barr, J. Fraser, E. Beckett, and Jas. Laing.

Messrs. JNO. LIVING & SONS, Forest Hill, London, S.W., exhibited a group of miscellaneous plants, most of them valuable foliage species, and including a nice specimen of *Asplenium Arthur Mallet*, and a few *Bertolarias* (*Silver Banksian Medals*).

A group of plants staged by Messrs. JNO. PEAR & SONS, Rompall Park Nurseries, Norwood Road, contained some capfully flowered double *Deutzias*, *Roman Hyacinths*, and *Cyclamens*, *Lily of the Valley*, and a winter flowering *Begonia*, &c., which considerably brightened the *Dreuzias* and other fine foliage species of which the group was composed (*Silver Flora Medal*).

Mr. THOS. S. WARR, Hale Farm Nurseries, Tottenham, made an exhibit of species of *Snowdrops* (*Galanthus*), and *Snowflakes* (*Leucojum*). Various *Iris*es also, including *Iris histrioides*, *I. reticulata*, *purpurea*, *I. Bakeriana*, *Chas. E. Frimond obconica*, *Victoria viridifolia*, and a few other hardy plants in flower (*Bronze Banksian Medal*).

Mr. GEO. WYBLES, gardener to Earl Percy, Syon House, Brentford, exhibited a group of forced plants, including a number of plants of *Staphylea trifolia*, and a few double *Deutzias*, *Hyacinths*, *Trillies*, of the valley, *Azalea mollis*, *Palos*, &c. (*Silver Banksian Medal*).

Messrs. BATE & SONS, King Street, Covent Garden, exhibited collections of several species of hardy flowers, and others in pots. *Scilla biflora*, *Iris reticulata*, *I. Kelloggii*, *Galanthus Elwesii* and *G. Harlowi*, a few *Colchicums*, *Narcissus minimus*, *N. mopalliphilus*, *Leucojum*, &c.

PRIMULAS were shown by Messrs. HENRY LAW & CO., Bush Hill Park Nurseries, Epsom, Surrey, and by The Garden of Slough. Both establishments being represented by groups of plants of a good strain. *Silver Flora Medals* were awarded in either case.

Mr. Josse Willard, gr. to the Baroness DORSET COURTES, Holly Lodge, Highgate, was the exhibitor of half a dozen excellent plants in flower, of the popular winter-flowering fibrous rooted *Begonia* *Guire de Secaux*. These were of considerable proportions, and grown in 8-in. pots.

Seedling plants of *Azalea mollis* were displayed by Messrs. B. S. WILLIAMS & SONS, Victoria Nurseries, Upper Holloway, who had half a dozen good specimens in flower, the blooms representing in each case a pleasing tint of colour (*Bronze Flora Medal*).

PRIMULAS were shown by Messrs. H. CANNELL & SONS, Swanley, Kent, who had a very large collection of showy plants of first-rate value, a *Silver-gilt Flora Medal* being awarded. A curious plant was given, which was a strain that has arisen as a result from crossing with the type known as "The Lily," such as *Frimondia pyramidalis grandiflora striata*, which has striped flowers upon a white ground; *C. pyramidalis alba*, *P. lutea alba nigrofolia*, which has yellowish flowers; *Pink Lily*, and *P. rotundifolia* (the very old *Sweet Primrose*), which was given by the strains, and their derivative value, was frequently remarked at the meeting. The large flowered (*loris*) *Primulas* were also well represented by large groups of particular varieties, of which the following are a few: *My Favourite* (pink), a capital flower in this section; *Her Majesty*, white; *Eyford* (very good); *Sweet Primrose* Blue; a very fine form of this section, *Eyford Purple*; *Delicata*, very pretty pale pink; *Swanley Giant*, *Cannell's Pink*, and *Cannell's White*.

Mr. ROBT. OWEN, Castle Hill Nurseries, Maidenhead, showed a few plants of a *Chinese Primrose*, called *Owens's Double Blue*, having pale bluish flowers, and Mr. J. CROOK, gr. at Ford Abbey, Chard, sent out *Violets* and *Primroses*.

E. PURNELL, Esq., Woodlands, Streatham, exhibited a group of *Daffodils*, in pots, and was awarded a *Bronze Banksian Medal*.

Messrs. T. CHIFFY & SONS, Taubridge Wells, showed a *Marbled Nel Rose*, described as a white one, but the colour of the flowers was not pure; also a number of plants of a very sweet purple-flowered variety named *Amiral Avellan*, which was recommended an Award of Merit.

C. J. LUGAN, Esq., Waltham Court, Horsham (gr. Mr. DUMCEN, exhibited some cutting flowers of *Lepagaria rosea*, *Warham Court* variety. It is a fine form of this popular and useful chaming plant, the flowers being very large, fleshy, and the habit of the plant extremely floriferous (First-class Certificate).

A *Clivia* with variegated foliage, named *C. aurea* strains, was shown by Messrs. H. B. MAY & SONS, Forest Hill Nurseries, London, S.W.; and Messrs. JAS. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, exhibited fine specimens of the profusely flowered, useful, and showy shrubby *Spirea*, *S. confusa*; also *Thiodora canadensis*, a very old inhabitant of our gardens, producing small blue-purple flowers, very similar to those of *Rhododendrons* of *Azara*; and a collection of varieties of their hybrid greenhouse *Rhododendrons*.

Mr. G. TAYLOR, gr. to Sir J. W. RAMSDEN, Bl. Byam, Ferrybridge, showed spathes of some seedling *Richardias*; and Sir THOMAS LAWRENCE, Bt., again displayed a very handsome variety of hybrid *Richardias*.

Messrs. R. WALLACE & CO., Colchester, exhibited a few of the very pretty spring-flowering *Iris*es, including *Iris histrioides*, *I. reticulata* var. *Kelloggii*, *I. histrioides* (see fig. 29, p. 105), and *I. Bakeriana*. A First-class Certificate was recom-

named the last named, which is certainly one of the prettiest of them. It was figured in the *Gardener's Chronicle*, March 5, 1896, p. 29, and we now repeat the cut on p. 105. It is a native of Armenia, and has been described by Prof. Michael Foster, in the *Gardener's Chronicle* and elsewhere, as being very variable, both in the size and tint of the flowers and in the period of flowering. The blooms are from two to three inches across. The tinge of the faller is yellowish, and the other portions being blue or whitish-yellow with violet blotches. The standards are blue.

Various specimens of preserved flowers and sprays of foliage were exhibited by the FEDERAL PRESERVATORS Co., 11, Coleman St., London. The system appears to be a very convenient and effective one. Sprays of Asparagus and other foliage plants, that had been cut and preserved for some months, presented a very fresh and natural appearance, and not glazed like some preserved specimens we have seen. The system, if adopted extensively, would appear to be capable of providing an abundance of choice and characteristic material for all seasons. Messrs. Yocco & Co., Stevenage Nurseries, exhibited a group of Lilies of the Valley.

Orchid Committee.

Present: Sydney Courtuld, Esq. (in the chair), and Messrs. J. O'Brien (Hon. Sec.), D. B. Crawshaw, Norman C. Cooken, E. Hill, J. James, H. Ballantine, E. Ashworth, John T. Gabriel, J. Williams, Van Gemmen, Fred. Th. H. Van G. Chapman, W. H. Young, T. W. Bond, Chas. Winn, J. Douglas, J. Garney Fowler, and T. B. Hayward.

A great number of plants were entered to go before the Committee, but only five secured Awards of Merit, and not one was deemed worthy of a First-class Certificate.

As usual, the group, as presided over by William, formed the chief attraction, and if in them there were few plants which the expert considered remarkable, the great variety of ordinary showy species was attractive enough to the majority of the visitors. The group staged by Messrs. JAS. VETTES & SONS, Royal Exotic Nursery, King's Road, Chelsea, which was awarded a Silver Medal, was the most extensive, and contained a very fine and varied selection of plants. Of novelties, *Lelio-Cattleya* v. *Violetta* (C. Gaskelliana V. L. purpurata) was one of the most showy, the flowers adhering in form more nearly to the *Cattleya*, and in the richness of colouring to the *Lelia*. The sepals and petals are light rose-purple, the petals being darker at the base, marked with red brown; the front lobe purple, streaked with violet and margined with lavender colour. (Award of Merit). Another pretty hybrid, which also secured an Award of Merit, was *Phalaenopsis Hebe* (*rosea* x *Sumbleriana*), which somewhat resembled a large *P.* in form and habit, the flowers being purple, rose, and white, the flowers being very attractive. Other good novelties and showy types in Messrs. VETTES'S group were *Cyrtopodium Leonidas villosum* - *Leucum* s, in which the petals and lip resembled a large yellow *C.* villosum, and the white dorsal sepal that of *C.* *Spicatum*; *Dendrobium Cytha elegans* (C. *Pinnatifida*); *Selenipedium Selenipedium candidulum*, a noble white and pink form obtained from S. Sedon; *Candidulum* and *S. exaltatum* Wallis; *Dendrobium* x *erosum* rosena and *D. x. caesium* leucopurpureum; *D. x. Cordelia*, of a delicate bluish-white colour; and *D. x. Cordelia* favosum, of the yellowish of *D. x. Cordelia*, and singularly marked *D. x. chloranthum* D. E. Elliot; *D. x. roseo-roseum*, *Platycheilus glaucosa calva*, *Epidendrum x elegantulum*; a large and varied collection of hybrid *Cyrtopodia*; and some good *Phalaenopsis*, &c.

Messrs. F. SYNDER & CO., St. Albans, were awarded a Silver Banksian Medal for a good entry in which were *Ondoglossum hystrix mobilis*, a magnificent variety, superior in size to one recently named "Pittianum," and belonging to the same class; a very fine form of *Cyrtopodium insignis montanum*, with large and well-formed flowers coloured like *C. x. Montanum*; some very fine forms of *Cattleya Trianae*, one with heavily-blotched petals in the way of *C. x. Beckhousiana* being specially good; a number of plants of the pretty *Physis* *Martine*, *Cyrtopodium nitens* - *Leucum*, a distinct hybrid; *C. x. Henri Van den Straeten*, a very handsome and large flower of the colouring of *C. Boxalliana*; a number of forms of *C. x. Beckhousiana*, including *C. Beckhousiana* *Skinneri*; a grand specimen of *Phalaenopsis Rochei*, with many racemes of its singular purple flowers; *Phalaenopsis Brandtii* (*P. assamica* x *C. x. Vetchii*), a pretty pink variety; *Dendrobium* (*nobile* x *Vardhamani*), with attractive white flowers tinged with rose, and a fine purple and yellow variety to the lip; and the new blue *Utricularia Forgetiana*.

Messrs. LINDEN, L'Herminette Internationale, Parc Leopold, Brussels, received a Silver Banksian Medal for a group of grand varieties of *Cattleya Trianae*, to two of which Awards of Merit were given, viz. *T. Imperator*, in which the colouring of the large labellum was almost entirely of a dark Tyrian purple; and *C. T. extima*, a noble flower with extraordinary breadth of petal and very finely developed lip, yellow in the tube, the front lobe crimson-purple, with a light margin; both petals and lip being crimson. Other fine varieties were *C. T. Beckhousiana*, with a fine purple and yellow colour to the lip; *C. T. illustris*, a splendid dark variety; *C. T. hlecta* and *C. T. princeps*, both good, and *C. T. Miss Linden*, with white sepals and petals and curiously tinted lip, all the segments being rather narrow.

Messrs. HENRY LOWN, Co. Clifton, staged a good group, in which were good examples of *Dendrobium* and other Orchids of the present season, the very singular *Ondoglossum Valentinei*, a supposed natural hybrid

with yellow flowers, blotched with brown and of very distinct character; *Dendrobium nobile* *Ballaunum*, *Lelia* *accipens* varieties; *Miltonia Roezli*, *Angreum sessuipetale*, &c. (Silver Banksian Medal).

Messrs. B. S. WILLIAMS & SON, Victoria and Paradise Nurseries, Upper Holloway, N., staged a group which were *Cyrtopodium Harrisonianum* and *C. x. Peltatum*; *C. x. Meivas*, *C. x. nitens* and *C. x. N. superbum*, *C. x. politum*, *C. x. Williamsianum*, *C. x. Sallieri aurum*, *C. x. venturatum superbum*, *C. Boxall*, *C. villosum*; some good varieties of *Cattleya Trianae*, *Colymbus cristata*, *C. sparsa*, *Lycaste fulvipes*, L. *Skinneri*, *Platycheilus glaucosa*, *Lelia* *guttata* - *ondoglossum* *Rosae* *albida*, and the clear yellow *Ondoglossum* *Hilli*.

The noble *WALTER ROBERTS* *Hill*, Tri g Park (gr. Mr. E. Hill), showed *Cyrtopodium Emu* (*bellatulum* v. *Spicatum*), a singular cross made at Tring Park. In form it much resembles *C. x. Meriliana*. The upper sepal is white closely dotted with dark purple; the deflexed petals yellowish with numerous small purple spots almost covering their surface; the lip greenish tinged with purple.

Messrs. C. COOKSON, Esq., Wyton, Northumberland (gr. Mr. W. Murray), again showed *Dendrobium Kenneth* (McCartie v. Benson), s, which had previously received an Award of Merit. The sepals and petals were similar in form, about 2 inches in length, and cream-white; the lip exhibited traces of the shovel-shaped lip of *D. McCartie*, and, like an *Orchis*, had a very distinct segment, its colour cream-white, with a pale, purple, purple tinge on the disc - a very singular and striking hybrid.

THOS. STATTOR, Esq., Stand Hall, Whitefield, Manchester (gr. Mr. R. Johnson), showed *Cyrtopodium Rolfei* (reputed parent *Leucum* x *Bellatulum*), which the Committee considered more probably *C. bellatulum* x *ovatum* var., or *Leucum*, or some other issue. At all events it is a very fine, striking, and distinct hybrid, the reddish dove-yellow labellum bearing some little resemblance to *C. Rothschildianum*. The upper sepal was white, with many purple spots; the petals were covered downwards, yellow, with a yellow tinge and stripes. Mr. Stattor also showed *C. Roberts* (*bellatulum* x *callisum*), a very richly-coloured purple flower; the fine *C. triumphans* (Sallieri *Hyacinth* x *caesium* superbum); and *C. villosum* *gigantum*.

MRS. H. ALBRIGHT, Esq., Harfield Hall, Wilmsholme, Cheshire (gr. Mr. H. Holloway), showed *Cattleya Trianae*, "Miss Beatrice Ashworth," a charming flower of the *C. T. Beckhousiana* class, and with a glowing Tyrian purple front to the lip, and feather on the petals.

WILLIAMS S. ELLIS, Esq., Hazelbourne, Dorset, sent the pretty pale purple *Andromeda* *Ellisi*, *Lycaste* *guttata*, its very fine *Ondoglossum Hartmanni* *Ellisi* variety, and *Lelia glauca*.

FRED. DE BRANDE, Brummenhof, Riesenbach, Zurich (gr. Mr. Schellert), sent *Lelia rosea* *Kienastiana*, a very handsome variety in which the front lobe of the lip and the edges of the side lobes are of a bright dark rose colour (Award of Merit), the singular *Ondoglossum chrysopictum*, *Ondoglossum cythosum* variety; *Lycaste plana*, *Messneriana*, *Andromeda* *Chlechteroni*, and some species of *Phalaenopsis*.

MR. H. APPLETON, Esq., Tyd y God, Weston-super-mare, showed *Cyrtopodium Quies* (*Onitise* - Hooker), *C. tessellatum* Appleton's var. (*onitise* - barbatum Warner).

REGINALD YOUNG, Esq., Liverpool (gr. Mr. Poynter), sent *Cyrtopodium insignis* *Youngi*, a very pretty, singularly spotted variety; *C. x. Lavina* and other *Cyrtopodia*. Mr. ASHBY, Cheltenham, showed a grand specimen of *Dendrobium* x *Amstrongii* *Cyprian* var., and a fine *D. splendissimum* grandiflorum with growths about 4 ft. high, and for each of which plants Cultural Commendations were awarded.

Messrs. HEATH & SON, Cheltenham, sent *Dendrobium nobile* *Heathii*, fine in form and bright in colour.

G. W. LAW-SCHNEIDER, Esq., Rawtenstall, Manchester (gr. Mr. Shill), sent flower of a fine *D. x. Currierianum*, T. W. SWINBURNE, Esq., Curlew Hall, Wincoboe (gr. Mr. Rendell), sent *Cyrtopodium* - *M. de C. Gleditsianum* var., a very fine and richly coloured *Ondoglossum Hilli* *Youngi* *burne* var., a very handsome flower of the *leucostegum* class; *C. villosum* *gigantum* and *C. Swinburnii* *magnificum*. The light Noble *GEORGE O'NEILL'S*, Highbury, Moor Green, Birmingham (gr. Mr. Embery), sent *Dendrobium Barkeri* *Youngi* var., *C. Beckhousiana* - *Cheltenham* var., a very showy hybrid with the flowers tinted carmine-crimson; and *D. aurum* s, *splendissimum grandiflorum* s, and which still retained much of the character of the female parent.

Fruit Committee.

Present: Philip Crowley, Esq., in the Chair, and Messrs. G. F. Chapman, T. J. Saltmarsh, A. H. Pearson, J. H. Vetch, J. Cheal, J. Wright, A. Dean, W. Pope, C. Barrin, W. Farr, J. W. H. Lattis, G. Reynolds, G. H. Sage, Geo. Wythes, H. Edmondson, J. Willard, F. Q. Linc, Jas. Smith, G. Norman, Robt. Eric Geo. Buryard, and F. Francis Rivers.

The competition for prizes in the classes for fruit in Apples and Peaches was distinguished by the fact that the Apple adjudged best was *Blenheim Pippin*, shown by Mr. W. H. DIVERS, gr. to the Duke of Devon, Belper, Grantham. The fruits were from a standard tree on free stock, grown upon strong dry in lime-bushes. Scarlet Nonpareil, shown by Mr. H. BOSWELL, Gomersbury House, Basingstoke, were the fruit from a tree from an orchard standard upon the crab stock, in light Emly soil in Middlesex.

The best Pear was *Passe Crassane*, shown by ROGER LEIGH, Esq., Barkham Court, Marlborough (gr. Mr. Geo. Woodward). The fruits were gathered from a west wall from a tree of the Quince stock growing in rich light loam. The specimens were capital for the month of February, and it is a very juicy, agreeable fruit.

Fourteen excellent fruits of the Lemon were shown by Miss THOMSON, Stanton Hall, Glos. well (gr. Mr. Harvey), and represented most successful cultivation (Cultural Commendation).

Messrs. T. F. RIVERS & SON, Sawbridgeworth Nurseries, Herts., exhibited fruits of an Apple named Prince Edward, a medium sized fruit, yellow striped with red, apparently a very agreeable fruit (Award of Merit). Also fruits of a conical shaped red-coloured Apple named St. Martin's, certificated last autumn. Messrs. Rivers also exhibited a collection of dishes of Apples, representing some valuable other varieties in capital condition. Orange fruits of the following varieties were also shown: St. Michael's, Egg Orange, Bittercourt, Tancya, Maltese, Blood, Dolcis, Dom Louise, and Lipon Lemon (Silver Knightship Medal).

A collection of sixty dishes of Apples and a few Peas was shown by Messrs. CHEAL & SONS, Lovell's Nursery, Crawley, Sussex. Some excellent specimens were noted of King of the Pippins, Newton Wonder, Jubilee, Peas Pool, Beauty of Kent, Warner's King, Prince Albert, Cox's Orange Pippin, and others (Silver gilt Knightship Medal). A collection of some varieties of Potato tubers was shown by Messrs. Yocco & DORNING, Stevenage, Herts.

DEVON AND EXETER GARDENERS' ASSOCIATION.

FEBRUARY 3. - The fortnightly meeting of this Association was held on Wednesday evening, in the Guildhall, when there was a very good attendance. Mr. J. ABRAMS, gardener to Mr. T. Kekewich, Peamore, occupied the chair. The essayist for the evening was Mr. J. MAYNE, gardener to the Hon. Mark Rolle, Bickton. The paper was of considerable merit, and dealt with the matter under consideration in a very practical manner.

The paper dealt with the forcing of Seakale, Asparagus, and other vegetables. The subject-matter of the various essays on the kinds of vegetables commonly forced in English gardens was excellent of its kind, and was conveyed in terms well understood by the audience. Varieties of Potatoes recommended by Mr. Mayne, were Old Ashleaf, Vetch's, Myatt's, and Rivers' Sharpe's Victor and Early Victoria. Mr. Plus Ultra and Canadian Wonder (Fuchs and Bane) were advised for forcing the first for early, and the latter for late supplies. Fursian Forcing and Sutton's Early Gem were spoken of as being capital forcing varieties of Carrot.

The discussion which followed the reading of the paper was of much interest, several members giving interesting experiences as to methods of culture in forcing vegetables generally.

Obituary.

BARON CONSTANTIN ETTINGSHAUSEN. - The death is announced from Graz by Baron Constantin Ettinghausen, the paleontologist and botanist, at the age of seventy-one. Deceased was originally a doctor of medicine, but devoted all his time and energies to botany and paleontology. In 1876 he was summoned to London to prepare a paleontological collection at South Kensington Museum. Subsequently he was repeatedly here re-arranging collections in the British Museum. He was the author of several works on botanical subjects, and wrote a large number of papers, which were published in the *Proceedings of the Royal Society*, and of other learned bodies.

HENRY BOSWELL. - The death occurred on Thursday, February 4, at Headington, near Oxford, of Mr. Henry Boswell, the eminent bryologist. The deceased gentleman had not only studied the mosses of Britain, but had an intimate acquaintance with foreign species, and his knowledge was utilised by many correspondents in different parts of the world. In his early days his attention was directed to the study of flowering plants, but subsequently he developed a greater fondness for the study of bryology. He possessed a large collection of mosses, which it is hoped will be secured by the University. In recognition of his services to bryological science, Oxford University in 1887 conferred upon him the honorary degree of Master of Arts.

FOSTER-MELLIAR. - On February 3, at Springorton Rectory, near Ipswich, Catherine Lucretia, the wife of the Rev. A. Foster Melliar, Rector of Springorton.

TRADE NOTICE.

We are informed by Mr. Albert F. Upstone that he has taken over the business of garden and agricultural seedsmen, carried on formerly by Messrs. Cobban & Son, Market Place, Kotherham. Mr. Upstone was formerly in the services of Messrs. Daniels Brothers, of Norwich, and Messrs. J. Veitch & Sons, of Chelsea.

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

CATTLE-FLY.—Would some of your Orchidist correspondents kindly inform "W. MCH." what time elapses from the laying of the egg to the appearance of the grub?

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns for Temperature (Daily, Accumulated), Rainfall, and Bright Sun. Rows list districts like Devonshire, Dorset, and others with their respective weather data.

The districts indicated by number in the first column are the following:— 0, Scotland; 1, Principal Wheat-production Districts; 2, Scotland, E.; 3, England, W.E.; 4, Midland Counties; 5, England, including London; 6, Principal Grain, &c., Districts; 6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; *Channel Islands.

MARKETS.

COVENT GARDEN, FEBRUARY 11.

Table of market prices for various goods including Anemones, Arums, Auriculas, Carnations, Chrysanthemums, Cyclamen, Euharis, Gladioli, Lilacs, Mignonettes, Narcissus, and Orchids.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table listing prices for various plants in pots such as Adiantum, Aspidistra, Azaleas, Chrysanthemums, Clivias, Cereus, Cycthemus, Daffodils, Draconas, Euphorbia, and Erica.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table listing prices for various fruits including Apples, Grapes, and Peaches.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table listing prices for various vegetables such as Artichokes, Asparagus, Beans, Cauliflowers, Cucumbers, and Horseradish.

POTATOES.

During the past week there have been larger arrivals, and with milder weather prevailing, prices for all but finest quality have a downward tendency. Dunbar Maincrop, 5s. to 7s.; Dunbar Saxons, 7s. to 7½s.; Lincoln Maincrop, 5s. to 7s.; do. Saxons, 5s. to 7s.; do. Glants, 5s. to 6s.; Blackheads, 4s. to 5s. John Beth.

NOTICES TO CORRESPONDENTS.

ASSIGNMENT OF NURSERIES, ORCHARDIST, MARKET GARDENS, &c.: G. B. E. and F. P. Only England and Wales are named as the countries to which the Act of 1896 applies. See p. 108 of present issue.

CARNATIONS FOR CERTIFICATE: E. M. There are two generally recognised authorities whose Certificates carry more weight than any others, viz., that of the National Carnation and Pink Society and the Royal Horticultural Society. The Secretary of the first is Mr. J. Douglas, Park Side, Ilford; and of the latter, Rev. W. Wilks, 117, Victoria Street, Westminster, S.W. It is always regarded as an advantage if plants in bloom be shown, not merely cut blooms.

CORRECTION: PARENTAGE OF ROSES, p. 96, Gardeners' Chronicle, February 6. Through inadvertence, the signature was printed David R. Wilkinson; it should have been David R. Williamson.

GARDENERS' RELIEF SOCIETIES: P. F. L. There are no societies established with the sole or secondary object of assisting gardeners when out of work. The United Horticultural Benefit and Provident Society, Secretary Mr. W. Collins, 9, Marindale Road, Balham, S.W., affords relief to members during illness, and may occasionally assist gardeners at other times. There are, we imagine, too many projects in the field this year already for a new one to stand any chance of finding supporters; but in any case there would be no harm done by pointing out the need for some such society.

MILDEN ON VINES: Frost grows. Maintain the vine-border in an equally moist condition till autumn, never letting it get dry. Remove all plants from the vicinity of the vinery that usually harbour mildew; let the air be warm and buoyant, as opposed to close, humid, and cool, which may

easily be done if the vinery is heated, and the mildew may give no trouble this year. Keep a lot of shallow saucers in the house constantly, filling them from time to time with a mixture of sulphur-and-water; also, smear the heating apparatus with a wash of quicklime and sulphur. Be careful in affording front ventilation.

NAME OF FRUIT: T. H. Probably, Annie Elizabeth.

NAMES OF PLANTS: Correspondents not assured in this issue are requested to be so good as consult the following number.—J. W. Mch. Gladioli gracilis, Jaeg.—J. T. L. Belfast. 1, Dendrobium chrysanthum; 2, D. primum (with Primoscoloured lip); 3, D. crassinode Barberianum; 4, send when in flower.

NURSERY CLERKSHIPS: A. C. We know of no book that indicates the precise duties of a nurseryman's clerk. In a nursery, as in other businesses, there are ledger, invoice, and correspondence clerks, cashiers, and ordinary book-keepers. In fact, the only difference between such clerks and those engaged in other trades is, that where possible, the former have some knowledge of the nursery or seed trade before engagement in the office.

PROPAGATION OF TREE PEONIES: Amateur. The method you name, that of grafting upon the fleshy roots of herbaceous species (P. albida and P. officinalis preferably), is a good one, and is frequently practised. This operation should be done about August. The scion should be made from a strong, moderately short shoot, which has no flower-buds, and be set upon a piece of root. Some operators choose one style of grafting, others another; but either of the veneer, cleft, or saddle methods will answer. The rootstock should then be potted and plunged in a frame, where they will not be above frozen. Cover the scion up a little way. Keep the frames closed, and apply a slight shading. Union will soon take place, but the plants may remain undisturbed till spring. Tree Peonies may also be propagated by layers, eyes with growing leaf, and occasionally by division.

RAFFLESIA SCHADENBERGII, WEIGHT OF: P. F. L. We have no record of the weight of a flower of Rafflesia Schadenbergii, but it is stated that Dr. Arnold, in company with Sir Stamford and Lady Raffles, lighted upon a flower of the species, named in their honour, Rafflesia Arnoldi, which weighed 15 lb. The genus, with one or two allies, is now comprised in the family Rafflesiaceae.

RED CURRANT STRUCK FROM EYES: R. A. It could doubtless be readily done in early spring by the aid of a little cautery, say, 55° to 60°. Slightly lamen would be a good kind of soil to use, as it does not favour decay.

THE LOWEST TEMPERATURE IN THE BRITISH ISLES IN THE LAST TWENTY YEARS: D. S. On January 17, 1881, the temperature fell to -16° Fahr. at Kelso, at Stobo to -15°, and Melrose to -10°. On January 26 same year the cold registered at Haydon Bridge was -6°; at Sorrel Sykes -9°. The winter of 1894-95 afforded instances of very low temperatures, but in no instance that we know of, were they as low as these.

ULSTER SHOW GROUP OF PLANTS, Gardeners' Chronicle for January 23, p. 63, for Mr. McKinnon, read Mr. McKinn.

VINE BEETLES: W. McH. We know of no better method than to catch them on white cloths spread underneath the plants, after scaring them with a sudden burst of light from a dark lantern.

CONTINUED LARGE INCREASE in the CIRCULATION OF THE "GARDENERS' CHRONICLE." IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS all over the world, and that it is preserved for reference in all the principal Libraries.

THE Gardeners' Chronicle.

SATURDAY, FEBRUARY 20, 1897.

GARDENING AND ARCHITECTURE.

MR. H. E. MILNER, F.L.S., Assoc.M.Inst., C.E., read a paper on Monday evening last before the Royal Institute of British Architects, on the subject of "The Garden in Relation to the House." Professor Aitchison presided, and there was a good attendance, including the Hon. Alicia Amherst (the author of *A History of Gardening*), Mr. Aston Webb, Mr. H. H. Statham, Col. Prendergast, &c.

Mr. Milner in his paper said that he proposed to speak of the treatment to be adopted in laying out grounds, particularly in their more immediate relation to the house, and to indicate generally a practical application of the theories advanced.

The formal treatment of gardens reached a high state of perfection under Elizabeth, when the architect who designed the house also laid out the garden, with its forecourt and broad terrace, its straight walks leading from it encompassing the flower-beds, and all harmonizing with the building. Little thought, however, was devoted to the treatment of the country outside beyond the planting of avenues.

Towards the end of the eighteenth century, fashion ruled the destruction of most of the old formal gardens, to be replaced in very many instances by a no less artificial and formal imitation of nature. The designers were not content with amalgamating with whatever was good of the old work a natural treatment of the outlying ground, or of giving greater breadth to the existing formal work, but swept away all this and replaced it by meaningless walks, by clumps of trees and shrubs dotted irregularly on the lawn and park, by a boundary of planting, by imitation of bits of natural scenery, by the introduction of artificial ruins and such-like objects, with the desire of making a picturesque landscape. The author then went on to speak of the happy mean between the formal and the picturesque treatment.

He differentiated greatly between the treatment of terraces, walls, steps, balustrades, &c., in stone and verdure. Architects should extend their work in the garden in connection with the building; but this work should go hand in hand with the composition of the greater picture, which the art of landscape gardening should produce.

The increased resources of modern horticulture should be taken into account; not merely the eye but the mind should be appealed to by the beauty of composition of line, colour, perspective, and grandeur; a liberal art should not degenerate into a mechanical one. Places differed in the conformation of the ground, in climate, in soil, in the requirements of the owner, in the amount to be expended, and in the possibility of an extension beyond the immediate precincts. It was, therefore, futile to lay down any hard-and-fast rules for design.

The author then proceeded to treat in detail of the site, the approach, the terrace, and the garden formation and planting.

The approach to a house should always appear to be direct, and any deviation from such directness should not only arise from, but should also be made to arise from, some decided obstacle. By direct was not meant straight. A straight approach required careful treatment. It was artificial in character, it could appropriately be used when an imposing or somewhat pretentious building was at the end of it, or when the distance was short, and when the country was flat. In sloping ground it should, if possible, be made against the slope of a hill. The gradient should be even and flat, or very slightly and continuously curved, otherwise it would appear not straight. If the ground be very undulating, a straight road is out of character with its surroundings.

A curved line of road was generally to be preferred, as being more easy of construction, more varied views could be obtained, its gradient could be varied, following within limitations the natural undulation of the ground; and the side slopes could be more easily and freely dealt with than the sides of a straight drive. Gradients, width of walks and drives, entrances, were here discussed in considerable detail by the author.

The lodge and entrance-gates belong to the drive, and should be parallel with, and at right angles to it, as distinguished from the highway. The face-line of lodge should be at least 10 feet from the edge of the drive, and its windows should be able to command the entrance and a certain length of drive. On entering by the drive it was advisable to create a good impression, and therefore to mark distinctly the difference between the dusty highway and the shaded, well-trimmed drive within the gates. Planting might be introduced on either side of the entrance, but once well inside, a view should be given of the outlying grounds, or stretch of park, or distant wood. A curved drive should not be planted continuously, but broad masses of planting introduced, at first to shut off the highway, at turns in the drive, and on the top or slopes of knolls round which the drive may wind.

The direction and level of the approach, and the character of the architectural features, ruled greatly the plan to be adopted for the treatment next the house.

The treatment of the terrace also depended very much on the architectural character of the building. By "terrace" was meant not only the narrow strip of level ground placed parallel with the house, or the more stately portion—often with architectural adornments—laid out along the face of the structure, but the whole of the ground that formed the base or setting of the building.

Having next discussed the various forms of terraces, the author passed on to the treatment of the garden proper, quoting partly from his book on the subject, which defined the system he advocated. So many considerations press in to vary design in the general plan of a garden, that arbitrary dealing by imposition of what may be termed paper designs, however ingenious, was ill-advised. The detailed plan should spring from the site as an adaptation of its natural, or created natural, features, and should not be forced upon the position, crushing it to an artificial scheme. To copy simply the design of another place is inadmissible. Considerations that rule in this connection were almost infinite—extent, geological formation, soil, existing

natural formation or features, climate and aspect, the display of distant beauty, conformity to outside influences, particularly to the requirements of the possessor, and the expenditure of money that may be made. There were points of similitude between the painter's art and landscape-gardening; but the landscape-gardener must consider that his colours change and grow—he must realise as he creates his picture that in a few years what now seems like a light green stroke of pigment to the painter may have become a tall tree, beautiful in itself, but of altered beauty, either helping or marring the landscape. He must follow Nature by adapting or garnering her beauties, and tutoring her, so to speak, to a display of them. But by following Nature was not meant a slavish imitation or reproduction of any of her particular scenes. Some were unattractive, some very inappropriate—all were subject to dissimilar conditions; and imitation in Nature as well as in art produced pettiness. But the spirit of the beauty of Nature, embodied as it were, in those of her works or features that express her majesty, simplicity, peacefulness, sweetness, repose, refinement, strength, and variety in form, colour, abundance, or any of her modifications as parts of loveliness, should be included and brought into juxtaposition in an ideal scene so far as it was possible to promote its natural development.

The terrace, the region immediately next the house, and the general arrangement of the walks and gardens, having been discussed, the author next dealt with the most suitable positions for planting trees and shrubs, principles of grouping, the effect of colour on distance, character of foliage, &c. He maintained that they should carry out in the parts surrounding the house the architectural feeling of the design in terraces, walls, steps, basins, beds, and so form a base; that they could still have the dignified and quiet delight of formal work—not a narrow curtailment of the whole design. But there was in addition a broader treatment beyond—a work difficult to proportion in relation to foreground, to broad lawn-spaces, to grouping, and choosing trees and shrubs for effect in size and colour, to directing the eye to desired points, to taking advantage of climate and character of the place either natural or acquired, to provision of light and shade in the undulation of the ground, and to a knowledge of horticulture. This art-gardening was far beyond the limitations of formal work only, for it could apply the balance and proportion of the latter, and, in addition, present a noble conception of art-work, in its execution of outline, surface-formation, and grouping, and draw into the picture the greater, broader, varied landscape.

In the discussion which followed,

The Hon. ALICIA AMHERST said she had listened with the greatest interest to the reading of the paper, and that she entirely agreed with all the writer had said. She thought with Mr. Milner that the garden should be laid out as much as possible to coincide with the architecture of the house, a rule which was being recognised by designer more and more every day. This fact ought certainly to be taken into consideration when new gardens were being made.

MR. ASTON WEBB proposed a vote of thanks to Mr. Milner for his paper, which he said was full of the most useful and valuable information, combined with practical details, and which, when printed, would make a most interesting chapter among the many interesting papers they had already heard. At their last meeting they listened to an hon. associate who was a sculptor, and that night they had experienced the pleasure of listening to an hon. associate who had dealt

with an equally interesting subject. It would be impossible to choose a more delightful subject than that of gardening. The first paradise on this earth was in a garden, and although that garden was not altogether a success, partly owing to what was planted in it, and partly to the people who resided there; still, at the present time no place was more charming than a beautiful garden on a summer's day. But the most delightful garden was incomplete without the house, just the same as a beautiful country house was incomplete without a beautiful garden surrounding it. Therefore it seemed to him that the two should go hand in hand from the very commencement. If he might say so, speaking to brother architects, it seemed to him most desirable that when they were building a house they should call in the gardener and discuss matters with him—the way he proposed to enter the house, and how he proposed to lay out the various buildings—before they put a stick on the ground, or even before they put a line on paper. That he considered was a most desirable, and, indeed, essential thing to do. The question whether the garden should be formal or otherwise, of course, interested architects, not only at the present day, as some people thought, but, as Mr. Milner had said, in the days of Elizabeth. He could not help thinking that the word "formal" in respect to gardening had been rather overdone, and very much misunderstood, not so much amongst architects but amongst their clients, the public. The formal garden, he took it, that they were striving for, and hoping to see more generally adopted, was the formal garden of England, and not that of Holland—although he had not seen many gardens there—or of Italy. They wished for the formal garden of Hampton Court Palace, on the one hand, or the garden at Hatfield House. Of course, the ground area at their disposal must naturally affect all they did. Mr. Milner had mentioned court-yards, and had said that the surrounding walls should be only 3 feet high. Surely he must have meant 10 feet. [MR. MILNER: No.] It seemed to him that in planning a garden there should be a certain sense of "mystery" sought for. The garden should be on the sunny side of the house, and the present Poet Laureate had exactly described what such a garden should be. Mr. Austen had written as delightfully on gardens as anyone in the world, and he hoped they should have more such works from his pen. The Poet Laureate had written—

"Alleys green should lead where none can guess."

That was the mystery to which he referred—paths should lead to some place which was not visible at the outset. A garden should have a good design.

"Man was designed to design."

A garden which was man's work should bear evidence of that fact, and any attempt at naturalism in the garden itself only led to dissatisfaction.

Mr. STATHAM seconded the vote of thanks. He said we were at present in a sort of reaction in regard to the question of what was a formal and an informal garden. For a long time—perhaps for twenty years past—we had discarded the formal garden as an old-fashioned thing. Now the matter had been revived, and people seemed disposed to go to the other extreme. Mr. Milner had no sympathy with them. He (Mr. Statham) did not think that hedges and trees cut into artificial shapes belonged to the formal garden. Hampton Court garden, as it existed at present, was an ideal specimen of a garden. But Hampton Court garden as it was laid out was a totally different thing. The formal hedges of elaborate designs had been done away with, and any advocate of the extreme formal garden could not but admit that it was far superior, and far more pleasant in its present form. Some people wished to imitate Nature so closely, that, like the poet Shenstone (who made an artificial perspective to his garden), they forget that their handiwork can be looked at from the other end.

Colonel PRENDERGAST said he would like to associate himself with others in saying how greatly he had been interested in Mr. Milner's paper. It was a

subject that touched their Institute more than many people were inclined to admit. Each generation had to meet the great difficulty of making the English home more charming than it was before. Fifty years ago it was the fashion to have a great field right up to the door of the house, and very beautiful that was to a certain extent. At that time a certain great lady, the Duchess of Sutherland, mother of the late Duke, a woman of taste, created an Italian garden at Trentham. She had at her disposal and close at hand the splendours of Minton to draw upon, but that was done away with! The result of all these things was that we had two parties in England. We had the formalist and the free gardener, and the only thing he wished to say about Mr. Milner's paper was that he had fallen into the old-English failing of getting a little between the two. He (the speaker) honestly

He had learnt differently from Mr. Milner's paper, which would prove extremely useful to everyone whose business it was to build houses.

Mr. MILNER, in reply, said what they had to do, was to find the happy mean in this question.

Colonel PRENDERGAST added that the subject of that evening had been greatly neglected, and he agreed that the architect and the landscape-gardener should work in harmony.

NEW OR NOTEWORTHY PLANTS.

POLYSTACHYA PLEISTANTHA, Krzl.*

I RECEIVED a spike and a photograph from Mr. Lauche, Director of the Gardens of Prince Liechtenstein, Eisgrub, Moravia. It is a very strange-looking

FIG. 32.—CRATOGEOMYS CARIBBEA: GARDEN HYBRID. (SEE P. 119.)

thought that the garden business could only be treated, in our days, by some such process. Of course, his remarks applied to new buildings. The modern method of placing houses on the highest ground, instead of in the valley, had completely changed their notions; and he agreed that the landscape gardener should be called in, in the first instance. In these days of bay-windows the gardener and the architect had an enormous advantage over those of olden times. Instead of keeping to a cut-and-dried plan, what they really wanted to discover was, how the place would look best to those who were to live there.

The CHAIRMAN, in closing the discussion, said they were extremely obliged to Mr. Milner for his admirable paper. He always understood that the landscape gardener looked upon himself as master of the situation, who, if he could really manage it, would leave a small corner of the ground for the house!

plant, the stem is short, and as far as I can judge from the photo, has no tendency to thicken into a pseudo-bulb; the leaves, about seven or eight,

* *Polystachya pleistantha*, KRZL.—Caulis ad 10 cm. alto foliosis; foliis distichis? late linearibus acutis ad 40 cm. longis racemis sub anthesi subaequantibus; racemis in specimeno ejus iconem photographiceam accipi, ad 25, simplicibus multifloris (80–100) bracteis parvis triangulis, rachis, bracteis, ovarioque scabris; sepalis dorsali oblongo obtuso, lateralibus triangulis apice obtusis omnibus extus pubescentibus apicibus incrassatis; petalis linearibus-oblongis obtusis, labelli lobis lateralibus maximis oblongis subtrapezoidalis obtusis, internodiolo minuto triangulo reflexo; callo incrassato in basi, linea lata elevata pro discum apicem usque utrinque in 1-mellam margine liberam dilatata, lobo disco dense pubescente; gynoestemil parte libera brevi hirsutissima, colorum generis.—Flores extus pubertatis lateri purpureo-suffusi et unculati; sepalis apice incrassata atro-purpurea, labellum pulchre luteum transverse purpureo-striatum; flos expansus ab eodem sepalis dorsalis labelli usque, 1–2 cm., inter sepalorum apices 1 cm. *F. Krásná.*

rise from the very base of it, they are broadly linear, about 30 to 40 cm. long, a length quite unusual in *Polystachya*. The two spikes arise from the axils of two of the upper leaves; they are perfectly simple, many-flowered (from 80 to 100), and somewhat nodding at the apex. Bracts short, triangular. The flowers have all the peculiarities of true *Polystachyas*, the large side sepals, the small dorsal sepal, and rather narrower petals; the lip also agrees very well with the usual form. The middle lobe is very small, and nearly disappears between the large side-lobes;

—even from *P. purpurea*, Wight. If the statement about the native country be a correct one, *P. pleistanthia* is the most eastern species of this widely-distributed genus. *P. Kronlin*.

CRATEGUS.

(Continued from p. 88.)

C. TANACETIFOLIA (Tansy-leaved Thorn).—A distinct and very beautiful Thorn, with leaves 1 to 1½ inch long, that are cuneate in general outline, but

Levant, and was introduced in 1789. Some of the branches end in a hard sharp point, but these are the only spines on our plants.

Var. glabra.—According to Loudon this is a hybrid between *C. tanacetifolia* and the common Hawthorn, and has shining leaves, and reddish-yellow fruit, only half as large as that of *C. tanacetifolia*.

THE NEW WORLD SPECIES.

C. Carrifreii s. s.—The precise origin of this Thorn is uncertain, but it has, no doubt, been derived from one or more American species—either as a variation or a hybrid (see figs. 2, 3). Mons. Carrière says it raised it from seed of *C. mexicana*, but Sargent places it first under *C. Crux-Galli*. It is probably a hybrid in whose parentage that species shares; the other parent, I should judge to be *C. tomentosa*. *C. Lavalei*, a plant originating in the Ségrez Arboretum, is now generally admitted to be the same thing, although the matter was some years ago the source of much controversy. In any case, it is one of the most handsome Thorns, and either for its foliage, flowers, or fruits is worth growing. It has ovate leaves of a dark lustrous green, toothed except at the base, from 2½ to 4 inches long, glabrous above, and pubescent below. It produces its flowers in May, and they are nearly 1 inch across, white, slightly tinged with rose. The fruits which ripen late, are then orange-red) are oval, and from ½ to ¾ inch long, with the serrated calyx-lobes at the top, and have a very pleasant flavour.

C. coccinea.—This is a most variable species, and one with which others, particularly *C. mollis* and *C. tomentosa*, have been confounded. It is handsome when in flower, although not so striking at that time as is *C. mollis*. The typical form has leaves that are nearly or quite glabrous, sharply and coarsely toothed, and smaller than those of *C. mollis*. The flowers are half to three-quarters of an inch across, white, with a greenish-yellow ring round the stamens. The fruit in all the forms is bright scarlet, and hangs downwards when ripe, in this respect differing from *C. tomentosa*.

Var. mucronata.—Of the varieties of *C. coccinea* in cultivation in Britain this is the most distinct; it has, indeed, until lately been commonly regarded as a species. It is chiefly remarkable for its numerous sharp spines, which are longer than those of any other *Crategus*, being usually over 3 inches, and sometimes 4 to 5 inches in length. The leaves have a thicker texture than those of *C. coccinea*, and the bright red fruits are more numerous, if smaller and less fleshy, than in the type. It was exceedingly beautiful during the past autumn. It is a smaller tree, and has a more western distribution in the United States than the typical *C. coccinea*. There are other named varieties in gardens, such as *dentata* and *maxima*, but they do not differ from the type any more than many unnamed forms do.

C. cuneolata (the Washington Thorn).—This species is distinguished from all the rest in the fact that it flowers later than any, but it is in other respects a distinct species. It is a small tree, said to be nowhere common in a wild state, and reaching in this country a height of 15 to 20 feet. The dark wood is armed with slender straight spines 1½ to 3 inches long. The leaves are of a dark glossy green above, paler beneath, and glabrous on both surfaces; their outline is somewhat triangular, but they are deeply three to seven-lobed, the lobes coarsely toothed; the blade is 2 to 3 inches long, the petiole about one-third as much. The flowers are small and white, and produced towards the end of June. The fruits are ripe in October, but remain on the tree for several weeks longer; they are of a bright red colour, about one-third of an inch in diameter, and orange-shaped. This is one of the neatest and most pleasing of the American Thorns, and ought to be oftener planted than it is. It was introduced in 1728.

C. cuneolata (Cockspur Thorn).—Of all the North American Thorns this is the most variable, especially in form of leaf and in habit. It is a particularly handsome tree, flowering and fruiting with great freedom. The leaves are, perhaps, the finest and

FIG. 33.—FLOWERING SPRAY OF CRATEGUS CARRIFREII.

the disc is covered with mealy substance, and in front of the middle lobe is a little plate or lamella, a character which does not occur very often in *Polystachya*. The flowers are purplish brown, hairy outside, glabrous inside. The points of the sepals are thickened and blackish purple.

It is very difficult to point out the closer affinities of the plant, although by its comparatively thin and excessively rich-flowered spikes of dull-brown flowers, it differs from all *Polystachyas* known to us. It is said to have been introduced from Borneo, but it is widely different from any of the three Indian species

deeply-cut into rectangular lobes, usually numbering five or seven, and irregularly toothed. Both surfaces of the leaf, as well as the young wood, are pubescent. The pure white flowers are amongst the largest in the Thorns, giving the tree a beautiful appearance towards the end of May. The fruit, which is ripe in September, is downy, ½ to 1 inch in diameter, yellow, and with a pleasant, rather Apple-like flavour; it can always be distinguished from the fruit of other *Crategus* by having one or more deeply incised bracts adhering to the base. This is a small tree, and one of the most desirable of Thorns. It is a native of the

most coriaceous in the genus, being of a deep lustrous green, obovate in the typical form and toothed, except at the base, where the blade tapers to two narrow wings running almost to the bottom of the petiole. The flowers appear in June after many of the *Cratogeomys* are past. The fruits are of large size and of a bright red, ripening late and remaining on the tree far into the winter. The leaves also remain on the tree for a long time, the species being almost evergreen in mild winters and in warm southern localities. Of the named varieties in cultivation, the following differ chiefly in the shape of the leaf: *arbitrifolia*, *ovalifolia*, and *prunifolia*. Vars. *linearis* and *pyramanthifolia* have narrower, smaller leaves, and the habit of both is peculiar, the branches growing out from the main stem in horizontal directions, and thus forming small, flat-topped trees. Other forms of *C. Crus-Galli* frequently show the same peculiarity, although not perhaps in so marked a way as these two; most of them are of more or less pendulous habit. Var. *berberifolia* (*Cratogeomys berberifolia* of Torrey and Gray) is the most distinct of the many forms of the Cockspur Thorn. As represented at Kew, it is a small, spreading, flat-topped tree, about 4 feet high. *W. J. Bean.*

(To be continued.)

PLANT NOTES.

GENTIANA STYLOPHORA.

It is probable that this year some seed of this remarkable Himalayan alpine plant will again reach England, and it may therefore be interesting to some of your readers to have my experience about it, particularly as hitherto the idea has prevailed that the seeds lose their germinative power during transit. It is best to prepare a bed in the open, and to sow the seeds as soon as possible. The place should be sheltered, partly shady, and not dry; here they should remain exposed to all weathers, in summer occasionally watered, and kept clean of weeds. After 12 to 15 months they make their appearance in the shape of two cotyledons not much larger than one-eighth of an inch. Great care must now be taken to keep off worms and slugs, which latter are very fond of such precious food; the plants do not grow, but the root only increases. In October or November, when they die down, some slight covering of light soil should be given, and the plants left alone till spring, when the cotyledons will again appear, and be much larger, the little root increasing again. Thus far my experience. I do not know what they may do this year, but I hope they may produce a regular stem. A somewhat peaty soil is preferred. As a rule, *Gentians* germinate very readily, but this one seems to be an exception, and my statement is only intended as a warning not to be too hasty in throwing the seeds away; they may be sown in pans, and kept for a summer, but in autumn the layer of soil in which the seeds are contained should be put outside and left alone. It seems necessary that the seeds should be exposed to cold and frost. My friend, Mr. Elwes, praises the beauty of this fine plant, he having seen it in its native haunts. The flowers are very large, and yellow in colour. *Max Leichtlin, Baden-Baden.* [The re-appearance of the cotyledons is a very remarkable circumstance, and should be attentively watched. Ed.]

ODONTOGLOSSUM CRISPUM.

This is, in all probability, the most popular of all *Orchids* in cultivation. During the past twenty years, the number of plants exported to Europe has averaged not fewer than 100,000 a year, thus 2,000,000. Of course, many thousands perish under cultivation in Europe, and some 25 per cent. are lost in transit. The demand for these plants in Europe is increasing. This year, several great *Orchid* growers have requisitioned 250,000 plants.

Hitherto, this *Orchid* supply has been obtained from the Pacho district, that is, from an area con-

prising some 500 square miles of forest, occupying numerous spurs and ramified ridges of the Eastern Cordillera.

Some fifteen years ago, this *Orchid* was obtainable in the Pacho district for a couple of dollars per 100. Then a peon collector collected as many as 200 a day. Now a peon collects about ten a day; and the price of collection has increased tenfold.

Of the 250,000 desired for Europe this year, it is hardly possible to supply more than a third, and this with strenuous efforts—efforts stimulated by the payment of exorbitant prices. Moreover, the result of these efforts will most seriously exhaust the available supply after the spring of next year.

The vast majority of these *Orchids* grow on trees, and large numbers of trees are cut down annually in order to secure the plants. But many plants are also found growing on the ground—on banks of moss, and on rocks; in general, but not always, under the shade of the forest—that is to say, they are frequently found in places more or less exposed to the sun. Frequently, too, when a clearing is made in the forest by fire, in rocky places, many thousands of plants spring up on these spots on which self-sown seeds require some eight years to become strong plants.

Another circumstance which has materially diminished the resources of the Pacho district, a circumstance that threatens in the near future to exterminate the plant—at any rate, for commercial purposes—is, thousands of acres of forest in which this *Orchid* has been dispersed are yearly cut down for the establishment of pastoral farms—a great industry on those elevated lands. Also, some eight years ago, during an exceptionally prolonged drought, many thousands of acres of forest, on which these plants abounded, were destroyed by fire.

In a state of nature seeds of this *Orchid* are produced in vast abundance. The seeds being extremely minute and light, float in the air. Millions are thus disseminated yearly.

The price of the newly-imported plants in the sale-room in London, according to the size of the plant, averages from half-a-crown to half-a-guinea each. It may be anticipated that the price will be augmented owing to the collapse in the supply. It may also be mentioned that special or rare forms of established plants in flower fetch from two to five, and even ten guineas each. Furthermore, about three per cent. of the plants obtained in the Pacho region consist of peculiar or unique varietal forms. The anticipation of such forthcoming novelties enhance the enthusiasm with which *Orchid* cultivators are inspired.

A few weeks ago I had the pleasure to forward forty plants of this *Orchid* to the Jamaica Botanic Garden for cultivation at the Cinchona plantation. Having resided ten years at that plantation, which was established under my supervision, I am well acquainted with the climatic conditions of the Blue Mountains of Jamaica. The temperature at the Cinchona plantation between 4,000 and 5,000 feet exactly coincides with the temperature at from 8,000 feet to 8,000 feet where *O. crispum* grows (latitude accounts for the difference of temperature equivalent to 2,000 feet). The wet seasons and the dry seasons are exactly similar on the Blue Mountains and on these Cordilleras.

From the upper limit of Coffee cultivation in Jamaica, about 4,500 feet, up to 7,000 feet, there is a very considerable extent of land under forest—a region comparable in extent with the Pacho region. It is impossible to conceive a more eligible tract for the naturalisation of this *Orchid* than is afforded between 4,500 and 7,000 feet in Jamaica. The way in which this enterprise—the naturalisation of this *Orchid* on the Blue Mountains—could be best accomplished would be to establish groups of the *Orchid* at intervals of probably a mile in the forest. Healthy plants tied to the trunks and branches of trees would require no further care. The majority of the plants would flower in about a year. After flowering, seeds mature in a few months. Thus within a couple of years myriads of seeds, by reason of their buoyancy, would be dispersed over the forest.

And it may be confidently predicted that in the course of ten years scores of thousands of plants would be naturalised and fit for export annually.

This *Orchid* thrives on the Cinchona trees, hence some hundreds of it might be established at the Cinchona plantation. Wider scope is afforded for cross fertilisation when a considerable number of plants are under treatment, i.e., large groups embracing varied forms. It would also prove advantageous to grow a small percentage of a few closely-allied species of *Odonatoglossum* in order to induce hybridisation. Thus the Cinchona plantation alone, on the trees and on the rocks, would become a nucleus of production.

It has been mentioned that some 25 per cent. (sometimes far more) of this *Orchid* exported from Colombia perish in transit to Europe. The plants are received from the peon collectors at a height of 7,000 feet above the sea-level. The plants are then packed in cases, carried on mules' or bullocks' backs two days over a lofty, bleak, and dreary ridge of the Andes, 11,500 feet in height, then fifty miles partly in carts and partly in short railways over the great savanna of Bogotá, then four days on mules to the river Magdalena, then about a week down that river to Savanilla. Thus a severe ordeal by reason of the violent changes of temperature and the time occupied.

There could be practically no loss by exporting from Jamaica, and the expense attendant upon transit from Jamaica would be comparatively light.

It may not be amiss to refer to a notable example of naturalisation furnished by Jamaica,* by which that island has been enriched to the extent of millions of money, and this by spontaneous production, i.e., Logwood. *Jamaica Bulletin.*

LÆLIO - CATTLEYA × DECIA ALBA (LÆLIA PERRINI ♀, CATTLEYA DOWIANA AUREA ♂).

Among the most beautiful and useful of the autumn and winter-flowering hybrid *Orchids* raised by Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, are the various crosses made between species of *Cattleyas* and *Lælia Perrii*, and one of the brightest and richest in colour was *Lælio-Cattleya × Decia*, which was shown on several occasions at the Royal Horticultural Society in 1895. But in 1896 out of the same batch Messrs. Veitch & Sons flowered a single plant bearing clear white sepals and petals, and a most delicately-tinted soft rose-pink labellum beautifully veined with silvery-white, and which was adjudged to be the best new hybrid *Orchid* of the year, upon its being exhibited at the Royal Horticultural Society as *Lælio-Cattleya × Decia* alba, Nov. 24, 1896, when it received a First-class Certificate. We have much pleasure in giving an illustration (fig. 34) of this unique variety, which being home-raised is doubly interesting as pointing to the manner in which albinos are produced from seeds in a wild state.

THE PRUNING OF FOREST TREES.†

Few things enrich the general appearance of a country, or increase the value of property, more than hedge-row trees, provided they are properly managed; but the training of trees planted in such open situations is seldom or never thought of. To manage this in a proper manner, young trees should be examined from the third year after they are planted, and if any more leading shoots than one are found to exist, the best one should be selected, and the others shortened to one-half the length of the selected shoot. This practice of examining the trees should be continued every year till they are about

* The non-orchid (*Platanus grandifolia*) is said to have been introduced by Mr. Wiles, whilst in charge of the Botanic Garden at Good Hope, and it is now very abundant on the higher lands of the interior.—[*See Jamaica Bulletin.*]

† A paper read before the Isle of Wight Horticultural Improvement Association, on Saturday, January 9, 1897, by William Cunningham.

15 feet in height. These shortenings, however (which should not be confined to superfluous leading shoots, but should include any branch which is gaining a disproportionate ascendancy over other branches of the same year's growth), should at first, and even for some time previous to this stage of the growth of the plant, be more cautiously done than is necessary to be observed afterwards, and should increase in severity as the tree approaches to, and after it is 15 feet in height. The process of examining

is of a greater length than the majority of the branches of the same tier, or if the whole are too long, they must be shortened in the case of trees intended for timber, after they are at and above 15 feet in height. This rule of shortening the branches of the new tier must also be applied to the undermost tiers of branches. In this manner all the under branches of any importance will have been shortened, which prepares them for the next operation.

After the trees are about 15 feet in height, the

spreading nature, such as the Oak, Beech, and others; but no branch, wherever it is situated, is to be cut off close to the stem, until such branch has become one of the lowermost tier. In this mode of shortening the branches, it will be seen that the tree will at all times present a head of nearly a conical form, and advantage should also be taken when shortening to reduce such branches, the pruning of which will balance the tree best, and produce the proper shape of the top; but in shortening the branches, too much should

FIG. 34.—LILIO-CATILEYA—DECIA ALBA; SEGMENTS, WHITE; LIP, LIGHT PINK, VEINED WITH SHALE.
(SEE P. 120.)

a tree is a simple one; it is done in a moment by the pruner casting his eye over the whole tree, and detecting the branches which require to be shortened, and, as a general rule, when it is found that any branch has a greater growth upon it than the leading shoot, it should be shortened by cutting off as much as will reduce it to half the length of the leading shoot, or even less. By this I mean any branch which is neither of greater thickness generally, nor near its junction with the main stem of the tree than the leading shoot is at the same distance from its top. And as trees produce only one regular tier of branches in each year, any branch should be shortened which

undermost tier of branches only should all be cut off close to the stem in one year. In the subsequent year another tier of branches should, in the same manner, be cut off, and so on every year afterwards, always cutting off only a single tier in one year. The same process of shortening the branches is meanwhile to be continued as before directed, but must be discontinued some years before the cutting of the tiers of branches is discontinued, so as to give a more extended top to the tree. All trees that have naturally conical heads, such as the Willow, Poplar, Larch, Silver and Spruce Fir, require longer heads than those trees that are of a

never be done in one year, nor will it be necessary to do so, provided the trees are attended to in the regular manner I have described.

There may be said to be various sorts or methods of pruning now in practice; e.g., first, close pruning; second, snag pruning; third, fore-shortening; fourth, topping or boughing.

CLOSE PRUNING.

This answers to a certain extent. The operation is performed by cutting the side branches off close to the bole of the tree, and you may expect that the bark and the timber will heal over, and the edges of

the wound become united if this operation is completed when the branches are young, or mere saplings, if the tree is in a vigorous growing state, and a few only of the branches cut off in one season. The object will be obtained without injuring the growth of the tree; but the system, from having been misunderstood, has been misapplied and carried to an alarming extent, doing incalculable injury, not only to individual owners, but to the country at large. Immense numbers of large boughs have been amputated from the trunks of trees, in the vain hope of the timber growing over the wound, and uniting with the stumps of the boughs left in the body of the tree. The bark and sap-wood do indeed sometimes grow over such wounds, but the stumps of the branches enclosed go to decay, become a canker in the bole of the tree, and the result is calamitous. It is the ready extension of the bark over the wounds in trees which has been the means of misleading so many people, because as they see that the bark unites, they take it for granted that the woody fibre does so also, and so, in fact, the growing part of the tree will do; but the stump of the amputated arm becomes a dead substance, and cannot unite with a living one. On the whole it is a dangerous practice to cut large boughs close to the stems of trees, particularly old and unthrifty trees. Young, thriving trees will succeed, if close pruned to a certain extent, but old, stunted, or full grown trees, never. The experienced timber merchant has a quick perception of the marks of this kind of pruning, which often reduces the value of timber one-half, and renders its sale to carpenters for purposes of fine work impossible.

SNAG-PRUNING

is a very pernicious practice. It is performed by cutting the boughs off several inches from the bole or stem of the tree. In old trees these stumps act as conductors for wet into the body of the tree. In young trees, the bark of the stubs throw out young shoots, which flourish for a time, but the heart-wood of these stumps decays, and has a similar effect to the stumps of boughs in old trees, which do not throw out young shoots. This system of pruning is very common to most parts of England: one can see little short dead stumps on almost every tree, particularly on trees growing on roadsides. It is mutilation of this sort that has created a prejudice against any description of pruning whatever, particularly with timber merchants and artisans.

FORE-SHORTENING

or cutting-in, is an approved method of pruning, and is admirably adapted to training hedge-row trees, to benefit the landlord, without doing much injury to the public. This operation is performed by shortening the over-luxuriant side branches, but not to cut them to a stump, as in snag-pruning. On the contrary, the top only of the branch should be cut off, and the amputation effected immediately above where a side shoot springs from the branch on which the operation is to be performed. This may be at the distance of 2, 4, or any number of feet from the stem of the tree; and suppose the side branch which is left (when the top of the branch is cut off) is also over-luxuriant, or looks unsightly, it should also be shortened.

The branches of trees pruned in this manner are always kept within due bounds; they do not extend over the adjoining land to the injury of the occupier or public. By adopting this system of pruning, the bad effects of close and snag pruning will be avoided, the country will be ornamented, and the community at large, as well as individuals, benefited.

BOUCHING AND LOTTING

is a system of pruning trees of a considerable size and age previously neglected, and where it is found necessary to remove large branches, leaving a stump in the form of a T-graph-pole.

Of the pruning of trees for picturesque effect on lawns and pleasure-grounds being a matter of taste, where we have not the standard of use to guide us, very little need be said.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Temperatures.—The prolonged absence of sunshine is very prejudicial to the health of Orchids, but during the past fortnight the weather has been comparatively mild, and there has been no difficulty in maintaining the necessary temperature, and at the same time opportunity has been afforded us to increase the ventilation in every department, but particularly in the cool house. When the outside temperature is about 40°, the bottom ventilators of the cool house may be left open by day and by night, and with a rise to 45°, fresh air should be admitted through the top ventilators. In the intermediate and warm divisions much caution must be exercised in the regulation of the temperatures should the mild damp weather continue, as with little fire-heat used, a surplus of moisture is likely to occur in the atmosphere. To prevent this, increase the fire-heat a trifle, and give as much fresh air as can be safely afforded, commencing each morning by opening the ventilators a little way, and then gradually increasing the amount as the inside temperature advances, and partially closing them towards evening, so that the fires need not be hard driven.

In the *Cattleya*-house plants of *Chysis aurea*, *C. bracteosa*, *C. levis*, *C. Linnæi*, and the handsome hybrids *C. Chelsoni* and *C. Sedeni* are now making their new growth. If the plants are strong enough to flower, they should be only sparingly supplied with water, until the spikes are seen to be getting ahead of the growths. The best time to afford more root-space is immediately after the flowers fade. As a small yellow *Thrip* is apt to get low down in the growth, the plants should be closely examined daily. *Chysis* may be induced to send out back-breaks by making an incision half-way through the rhizome between the old pseudo-bulbs, and the operation may best be done at the present time. In this way specimen plants may be obtained; but if it is desirable to increase the stock, the rhizome may be completely severed when the back growth is sufficiently flowing, and the divided piece potted-off singly after flowering.

Orchidoglossum-house.—At the coolest end of this house a place should be found for the following *Orchidiums*, all of which deserve extended cultivation:—*O. macranthum*, *O. undulatum*, *O. Leopoldi*, *O. serratum*, *O. Loxense*, *O. monachium*, *O. superbiens*, *O. lanelligerum*, *O. Kienstianum*, and *O. zehriannum*. These plants luxuriate in a cool moist atmosphere, and it is good practice to syringe well between the pots two or three times a day, or more frequently if there be exceptional aridity in the external air. The aerial roots from the long creeping rhizome of *O. zehriannum* should be well moistened at least once each day. Plants of the above species requiring to be repotted should now be attended to, as nearly all of them are showing new roots. Pots of moderate size should be employed, which should be thoroughly well drained. These *Orchidiums* cannot retain their roots for any length of time in compressed material; and the compost should consist of lumpy fibrous peat and sphagnum-moss, with a good number of thick pieces of crock or charcoal. It is not prudent to disturb the roots of any plants that have made much growth, or are producing flower-spikes. If the compost be in a poor state, however, it may be carefully picked out and the roots resurfaced with new material. Examine these *Orchids* every night, or slugs will cause irreparable damage to the tender roots and flower-spikes. *Orchidoglossum* Edwardsi, *O. Lindenii*, and *O. ramosissimum* are very similar in habit and manner of growth to the above-mentioned *Orchidiums*, and require the same kind of treatment. The rare *Orchidoglossum retusum* and *O. aspidochilum* are now starting to grow, and may be repotted if necessary, and placed at the warmest end of this house. The same remark applies to such pretty *Orchids* as *Sarcophilus Fitzgeraldii*, and *S. Hartmanni*. These small-growing species may be suspended from the roof-girds in teak-wood baskets or shallow pans; and sphagnum-moss is sufficient as a rooting material. *Orchididium Sophroanthus*, a very pretty little plant with scarlet flowers, may be grown freely in small pans suspended well up to the light. Like all other *Orchidiums*, it requires but little compost to root in; only a very thin layer of peat with a little moss being necessary. *O. Lawrenceanum* succeeds best if trained upon teak-rafts, with the roots at least 1 inch apart, to allow a free circulation of air amongst the roots. The lower

part of the raft should be inserted into a pot, and firmly fixed with crocks, over which a layer of sphagnum moss may be placed for the retention of moisture. *Orchidiums* require an abundance of water during growth.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

The Plinery (continued from last issue).—Should white or brown scale or mealy-bug be observed on any plant, it should be thoroughly freed from these very troublesome and injurious insects before the plant is potted. The following is a good formula to use against either: put $\frac{1}{2}$ lb. of soft-soap and one wine-glassful of paraffin in 3 gallons of water at a temperature of 110°, thoroughly mix both before and during use, and with this mixture syringe the plants all over, but be careful that the mixture does not remain in the axils of the leaves, and as a means of preventing which the plants should be syringed fifteen minutes afterwards with soft warm water, and left on their sides to allow of the water draining away entirely.

Ripe Fruits.—Any ripe fruits not required for immediate consumption may be lifted out of the hot-bed and placed in a dry cool-house, and they will keep in good condition for a longer time than would be possible in the fruiting-house. If this cannot be done, let them be cut with a long stalk and hung crown downwards in the Grape-room.

Strawberries.—Those plants whose forcing began in the month of November will now be rapidly developing fruit, requiring constant attention in the matter of affording water and manurial aids. In very dry positions the plants may be syringed twice a day in sunny weather; but discontinuing the syringing and the manure as soon as the fruit begins to colour, and supplying fresh air in increased volume, even leaving small openings on day and night when the weather is mild, otherwise the fruit will be deficient in flavour.

In whatever structure Strawberries are placed, they should not be far distant from the roof-glass, and ventilation should be abundant in mild sunny weather. In the fruiting varieties are best out in the open as far as possible, so as to avoid all incitement to grow for the present. If any sort of protection be afforded these, the ordinary cold frame, with the lights put on during drizzling rains or severe frosts, will suffice.

Successions.—The next batch to be raised should now be in full flower, requiring to be kept rather drier at the roots and all top, but avoiding extreme dryness. When in flower the syringe may not be used on them till a sufficient number of fruits are set and a few over, to allow of some amount of thinning being done. Fruiting plants should have a few birch twigs or neat dead sticks and matting to support the fruit-stalks. No plant should be forced that has not been top-dressed with rich loamy soil made firm around the crown. Later batches may be brought on in cool-houses and pits, not so much heat being now required in getting them to start. Clean each plant from dead leaves, ascertain that worms are not hibernating in the soil, and afford the plants one fumigation with tobacco in some form before the flowers appear.

THE KITCHEN GARDEN.

By W. PARR, Gardener, Highclere Castle, Newbury.

Onions for Exhibition, &c.—From sowings made in boxes in January the seedlings will now be ready for pricking out thinly into other boxes of prepared soil. A compost of three parts rich turfy loam and one part leaf-soil will suit them well. Press the soil firmly into the boxes, and allow it to become warm before the Onions are removed to it. Give each plant about 2 square inches of space, and keep the atmosphere rather close for a few days, after which ventilate carefully, and increase the quantity as the weather may permit so as to induce dwarf, sturdy growth. Autumn sown Onions may now be planted out, and as they come into use at a time when the bulbs of the previous season are over, they repay any extra care bestowed upon them. Select a somewhat exposed, rich piece of ground, and plant them 6 inches apart in rows 3 inches asunder. When the plants are established, an occasional dusting of fresh soot will be of great benefit; or if extra large bulbs are desired, a little guano may be sown over them in showery weather. The best varieties are good strains of White Lisbon and Giant Rocca.

Shadoks, &c.—If these were not planted in the autumn, the work should be done at once. Let the rows be 1 foot apart, and the sets 9 inches distant from each other. A moderately light rich soil is one that is most suitable for these, and for Garlics, which may also be planted at once. Clives require to be taken up, the clumps to be divided and replanted on fresh ground.

Cauliflowers, &c.—Cabbages or Cauliflowers that are being raised in heat must not be allowed to remain thickly crowded together in seed-beds, which they will be in too great degree of heat, or they quickly become weak and spindly. Thin the plants early and severely, and keep them well up to the light. When the first true leaf has developed, pick them off into boxes of rich soil, or on beds near to the glass in frames. Keep a close atmosphere for a day or two until fresh growth is made, then ventilate more and more freely until hardened off for planting outside. Plants wintered in frames may be put out if the land be sufficiently dry. Lift them with a good ball of earth and plant with a row that they will experience but little check. In the event of severe frosts they may be covered with flower-pots. Varieties that make medium growth may be planted 2 feet apart by 18 inches, whilst those of stronger growth, as Veitch's Autumn Giant, will require at least 6 inches more space each way. A little fresh soot dusted along the rows will tend to ward off the attacks of slugs, and prove otherwise beneficial to the plants.

Carrots.—Some early Horn Carrots should now be sown on a south border or other warm situation. These are by no means tender, and they will provide succession to those forwarded under glass. Sow in drills 1 foot apart, and about 1 inch in depth, covering the seed with a little fine sandy loam, and thin out the seedlings as soon as they are large enough to handle.

PLANTS UNDER GLASS

By G. H. MAYCOCK, GARDENER, LITTON HOSE, LITTON.

Stove-plants.—The season having arrived when plants begin to exhibit activity in root and shoot, repotting and surfacing have become necessary items of the work. A beginning may be made with the climbers, such as Stephanotis, Allamanda, Clerodendron Balfouriana, Diplazeanus, Passiflora, &c. Assuming the necessary pruning was carried out in December and early in last month, and the plants have been resting in the interval, they should now be making an effort to grow. The beds or borders in which Stephanotis grandiflora may be planted should have some of the inert exhausted soil removed, replacing it with new, which may consist of loam one-half, peat one-fourth, rotten manure one-fourth, and a good proportion of sand and charcoal. This should be worked in among the upper roots and made firm. Specimen plants standing in pots which were not potted last year, should be shaken out and repotted in a mixture consisting of three parts half-decayed turfy-moss, one of leaf-mould, with charcoal and sand added. After repotting, &c., let the plants be well cleansed, and the shoots trained thinly over the trellis; this done, the shoots, when they grow may be allowed to ramble freely till signs of flowering are noticed, when a plant may be tied into proper shape if it be in a pot, or have its growths suitably disposed on the roof-trees. Allamandas, of various species, and Clerodendron Balfouriana, may be similarly dealt with. Diplazeanus require very careful management, besides being kept as free as possible from insects, and afforded ample drainage. At the present time Diplazeanus may safely, and with benefit to their well-being during the coming season, have the stems and every other part cleansed with an insecticide, using a sponge in the operation. These plants require a good amount of soil in which to root, the size of the pot being determined by the amount of space to be covered. Usually, pots measuring 10 to 12 inches in diameter are sufficiently large. On proceeding to root, shake out much of the soil from the roots, thus reducing the old ball in size, but not cutting off any of the healthy roots. Having reached a good lot of clean crocks in the pot, with rough fibry peat and loam over these, proceed to fill up round the ball with a mixture consisting of peat three-quarters, leaf-mould one-fourth, and plenty of sharp sand, and charcoal not broken too finely. When on examination new roots are seen to be freely permeating the soil, plenty of water should be afforded, and the tops syringed with warm water on fine days. Diplazeanus should be examined once a week for insect enemies, as if these gain a foothold much mis-

chief occurs. Bougainvilleas, which may be planted out in the stove or warm greenhouse, should now be attended to in the matter of surfacing, and started to grow. If the soil is in good condition it will suffice to top-dress only, nutrition when it is required being afforded in the form of liquid-manure. If, however, the shoots, when they break appear in the least degree weakly, a light sprinkling of Chay's fertiliser may be applied at intervals. The temperature of the stove may now be raised to 65° by night, 75° by day, and the water used for all purposes shd not be at a lower temperature than 75°.

Wivoras.—A number of these plants about this date should be placed in more warmth; and those that were repotted last year should have the leaves cleansed with a wet sponge, afforded some kind of artificial manure, and be placed in an intermediate-house, and in such a part of it that they can be readily syringed. Established plants which may not have been disturbed at the root for several years, will probably benefit from a repotting into clean, well-cropped pots, using sound, turfy loam, without much of the fine particles retained, and potting pretty firmly. Clives are not particular as to soil, or difficult to manage, and should be found in every collection of plants. Some of our stock of these plants which have wintered in an unheated structure, and not been repotted for seven or eight years, were placed in heat a fortnight ago, and to-day I notice that they have in some cases upwards of twelve to fifteen spikes on plants growing in 12-inch pots; and this too without much attention being paid to their needs during the summer months.

THE FLOWER GARDEN.

By CHARLES HERRIN, GARDENER, DROPMORE, MALDENHEAD.

Annals and Biennials.—Seeds of these plants, if not already in stock, should be obtained at once, as several species will need to be sown shortly, as well as a few perennial species. Easily raised from seeds, many of these plants are excellent for summer bedding; and should the stock of Pelargoniums be deficient, an adequate stock of annuals and biennials may be raised during the spring. Apart from the furnishing of flower-beds, there are corners and spaces in the herbaceous borders that require a few plants in the summer, especially after the foliage of bulbous plants has ripened and died off, and for this purpose annuals are extremely valuable. Verbenas from seed, planted in mixed colours in beds, have a very good effect; and from a good strain the flower-trusses are larger and the growth more free than upon plants obtained from cuttings. Sow the seeds during the next two or three weeks in shallow boxes or pans filled with light sandy soil; cover them lightly, and place in a temperature of 60°. The seedlings will appear in about a fortnight, and as soon as they are large enough to handle, they may be pricked off into other boxes. Antirrhinum may be obtained in both tall and dwarf strains from seed, and the distinct colours of white, crimson, and yellow come fairly true. These should be raised similarly to the Verbenas. Zinnias, double and single-flowered, come true from seed when obtained from a good source. The pompon Zinnias are useful as cut flowers, and being of dwarf growth, may be used in small beds. Sow the seeds in frames on a mild hot-bed about the middle of April. Single seedling Petunias may be used for bedding, or for trailing over the sides of window-boxes and large vases. The useful Gallardia of the grandiflora type is well known, and although a perennial, may be flowered the first year after sowing. C. Lorenziana is a free-flowering annual, producing double flowers of various colours. For sowing in the open borders or in frames for transplanting, many of the following are adapted for embellishing the borders, and for furnishing flowers for indoor decorations:—Bartonia aurea, Coreopsis coronata, C. atro-sanguinea, C. tinctoria, C. Drummondii, and C. grandiflora—all annuals, except the latter, which flows abundantly the second year after sowing; Campanula edulis in many varieties, Centaurea Margaria, and Cyanus minor; annual Chrysanthemum double and single; Clarkia elegans, C. rosea fl.-pl., C. integrifolia and C. pulchella, Collinsia bicolor, Corvolvulus minor, Eschscholtzia crocea, Oenothera (Godekins) in variety, Limnium flavum, and L. grandiflorum L. coccineum, the Amarantus caudatus (Love-lies-bleeding), the Malope rose, white and crimson; Nasturtium, Phacelia (Campanularia), a beautiful blue; Poppies, and Sweet Sultan. Other important annuals are Salpiglossis and Sweet Scabious, Sun-flowers, Margolles, Nilox Drummondii, and Stocks

and Asters. Of the latter, the Comet, in several colours, is a useful kind for cutting purposes.

Mignonette.—To obtain early spikes of flowers from the open, a number of 60-sized pots should be filled with light soil, and about eight seeds sown in each. When the seedlings appear, they should be gradually prepared by a decreased temperature for planting in the open, when this is safe.

Gypsophila paniculata, an extremely elegant, barely perennial, may be raised easily from seed. If sown now in heat, and the seedlings potted off as soon as large enough into small pots, grown on for a short time in a warm house or pit, and eventually hardened-off before planting out, this will give a little flower the first year, and a great abundance the next one.

THE HARDY FRUIT GARDEN.

By H. W. WARD, HAYLEIGH, ESSEX.

Planting Strawberries.—If the ground has been manured and trenched as advised in the calendar for January 23, the plants may now be put out in rows 20 inches asunder, and the same distance allowed between the plants in the rows. Keep the centre of each plant well above the soil, and make the latter firm about the roots in planting. Equally satisfactory results may be obtained from plants set out triangularly in clumps consisting of three plants in rows 2 feet apart, and at the same distance in the rows, allowing a space of 4 or 5 inches between the plants in each clump. After planting, lay on a surface-dressing of short manure between the plants, but do not dig it into the ground.

Raspberries, Gooseberries, Currants, &c.—In cases where the planting of these fruits has been delayed from some cause, the work should be completed forthwith. Plant in well-prepared ground, and afford a space of from 4 to 5 feet (according to depth and fertility of soil) between the rows of Raspberry-canecan, and from 1 to 6 inches between the canes in the rows. Treat the soil pretty firmly about the roots in planting, and afterwards apply a surface-dressing of short manure 2 inches thick. For directions in regard to planting Gooseberry and Currant bushes, I would refer the reader to p. 58, *Gardeners' Chronicle*, January 23.

Peaches, Apricots, and Greengage Plums.—If the means recommended at p. 91 for protecting the blossoms of these fruits have been adopted, the blinls should be let down over the trees every evening when frost is expected, securing them in position, and raising them the following morning as soon as the sun shines on the wall; or earlier, should there not be any frost.

Vines on Walls.—Vines growing upon open walls require the shoots of last year's growth to be cut back to within one bud of the main shoots. Rub any loose bark off, and should the leaves have been infested by red-spider or mildew last year, paint the wood with a paint-like mixture of clay and a little soot, sulphur, and soft-soap. Apply this to every part of the branches, dabbing the mixture well into and around the old spurs, as being the most likely place for insect pests secreting themselves; and if necessary lime-wash the walls, if this can be done without disadvantageously altering their appearance. In the case of good brick walls having permanent nails driven therein for tying the Vines to, these being washed with a solution of soft-soap water and petroleum will destroy any insects or larvae that may be adhering thereto.

Figs.—The pruning of Fig-trees should be deferred till the end of the month of April or the first week in May, but the matter will be referred to again in this column in due time.

MR. JOHN LAMBERT, gardener to the Earl of Powis, and well-known as a successful horticultural exhibitor, was the recipient recently of a presentation gold watch, subscribed for by members of the Welshpool Horticultural Society, in recognition of the services he has rendered to the society as assistant secretary and in other ways since its re-constitution five years ago. The society has reason to congratulate itself that in so short a time it has achieved a position that enables the committee to spend a sum of £500 upon a one-day exhibition. We join in the good wishes expressed on behalf of Mr. Lambert at the presentation meeting.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY of the PAPER, sent as early in the week as possible, and duly signed by the writer. Unpaid, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, FEB. 21.—Herefordshire Gardeners meet.
 THURSDAY, FEB. 25.—Kew Guild; Annual General Meeting of Members.
 SATURDAY, FEB. 27.—Royal Botanic Society meet.

SALES.

Herbaceous Plants, Roses, Carnations, Begonias, &c., at Protheroe & Morris' Rooms.
 MONDAY, FEB. 22.—Nearly 1000 lots of Border Plants, Bulbs, Roots, Roses, &c., at Stevens' Rooms.
 TUESDAY, FEB. 23.—Imported and Established Orchids, at Protheroe & Morris' Rooms.
 Japanese Lilies, Azaleas, Bees, Palm Seeds, Geraniums, Herbaceous Plants, &c., at Protheroe & Morris' Rooms.
 Sale of the Leasfield Property, "Winnona," Ruislip Heath, near Ballerkey; also the Goswell and Lease of the Rose Nursery, Savan's Lane, Highbury, at the Mart, Tottenham Yard, E.C., by Protheroe & Morris.
 Store and greenhouse Plants from Ghent, Roses, Fruit Trees, Shrubs, Border Plants, Bulbs, &c., at Stevens' Rooms.
 Importation of Burmese Orchids, by order of Messrs. H. Low & Co.; 300 Cases of Japanese Lilies, as received for the Trade, at Stevens' Rooms.
 THURSDAY, FEB. 25.—Imported and Established Orchids, at Protheroe & Morris' Rooms.
 FRIDAY, FEB. 26.—

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—40°.

ACTUAL TEMPERATURES:—
 LONDON.—February 17; Max., 51°; Min., 35°.
 PROVINCES.—February 17 (6 P.M.): Max., 41°; Scilly; Min., 37°; The Scow.

The Garden and the House.
 MR. MILNER did good service on Monday evening last when he faced the architects in their own domain. Perhaps he found them less aggressive than he expected. From the report given in another column it is evident that he, at least, took a middle course, avoiding the extremes in which some folks seem to delight, and recognising that good sense and good taste may be found even in the architectural body, in spite of some apparent exceptions to the contrary, manifested in certain books noticed by us at the time of publication. Mr. MILNER's task was not a difficult one—at least, it was not difficult for him. His subject chiefly was the relation of the garden to the house, and especially of that portion of the garden in immediate proximity to the mansion. There are some, on the one hand, so enamoured of their garden-geometry and their carpet-beds, that they would introduce them into the pleasure-grounds and into the flower-garden; even the Rose-garden may not entirely be exempt from their intrusion. On the other hand, there are some to whom the delicious picturesqueness of the typical cottage garden and its inmates appeals so strongly that they would introduce them bodily on to the terrace walks, where the flowers and growths, so beautiful in their proper place, would be as

incongruous as fish out of water. The beauty of appropriateness is apt to be ignored by both parties; they forget that what is beautiful and appropriate in one situation is not so in another, and similarly that the plants adapted by their contour, their "habit," or their colour, for one spot are terribly out of place in another situation. If these generalities be admitted, then it seems obvious that the landscape gardener and the architect, instead of being antagonistic, should take sweet counsel together, so that the garden in the immediate vicinity of the house shall be in harmony with the architectural lines and masses of the building, whilst the windows shall be so many frames encompassing the pictures made by the skilful landscape gardener, and permitting them, together with the distant prospect, to be seen to most advantage. The architect has, of course, no more to do with the garden proper, away from the house, than the gardener has with the planning of the house itself. Each should have a free hand in his own domain, whilst conjoint action may most beneficially be exerted at the points of contact.

Nay, more, we think the landscape gardener should always have a voice in the selection of the site when a new building is contemplated. It is not uncommon to find houses placed where no landscape artist would have placed them. Again, it has happened in our experience to see a garden planned and carried out, with the site for the mansion duly arranged for, but changed subsequently by the architect, to the stultification of the ideas of the gardener.

Fortunately there is one feature in almost all gardens which, in a sense, acts as a peacemaker, harmonising incongruities, and linking opposites together, and that is, of course—the lawn. The crudities of colour, the barbarities of form are softened by this delightful adjunct; and what setting is there more beautiful for the fine lines and noble proportions of the architect's work than well-kept turf?—as witness many of our cathedral closes, such as Salisbury, Canterbury, or even, of late years, Westminster.

Nothing but good can come from the conference and interchange of opinions between landscape-gardener and architect. We congratulate Mr. MILNER on the success of his effort, and we are grateful for the hospitality extended to the representative of the gardeners by the architects.

EUPHORBIA PULCHERRIMA AT SANTA BARBARA, CALIFORNIA.—Few plants are more popular for winter-decoration than Euphorbia (or Poinsettia) pulcherrima, from Mexico and Central America, where it is called "Pastora" and "Flor de Pascua," in allusion to the fact that it is at its best for Christmas. The accompanying illustration (fig. 35) was taken just a few days before Christmas at the residence of Mr. C. A. EDWARDS, in Santa Barbara, California. To persons familiar only with Poinsettias well bloomed in 5 or 6-inch pots, this will make a good show of what we can accomplish in gardening on this coast, where "heads" of Poinsettias 2 feet across have been actually measured by myself. This one plant is about eight years old, and is strongly cut back every year in spring. The tropical appearance of the scene was enhanced by hundreds of large showy butterflies, Danae archippus, I believe, hovering all day long over the dazzling bracts. Dr. F. Franceschi.

KEW GUILD.—The annual general meeting of the Kew Guild will be held in the lecture-room of the Royal Gardens, Kew (entrance by Melon-yard gate), on Thursday evening, Feb. 25, at half-past 7.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, February 22, 1897, when the adjourned discussion on the paper read by Mr. J. WILLIS BURN (Associate), at the last meeting, entitled "Allotments and Small Holdings," will be resumed; and (should time permit) a paper will be read by Mr. C. H. HOOVER (Fellow), entitled "Fruit Growing as an Auxiliary to Agriculture." The annual dinner will take place on Wednesday, February 24, in the Victoria Hall, Hotel Cecil, Strand Entrance, East Block.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—The monthly meeting of this Society was held on Tuesday, Jan. 9, at 25, Westgate Road, when Mr. JOHN BULLOCK presided. A lecture, illustrated by lime-light views, was given by Mr. H. INNES on the "Cryptogams and lower forms of Plant Life." (Commencing with the Algae, the lecturer described in a very interesting manner the various forms of reproduction up to the Ferns. The lecture, which was highly instructive, was listened to with marked attention.)

THE LEICESTER CHRYSANTHEMUM SOCIETY, which was stated at the Annual Meeting held recently, had last year an income of £117 12s. 7d., including a balance from the previous year of £28 19s. 1d. The expenditure amounted to £81 16s. 7d., leaving a balance of £35 16s., and showing a profit on the year's working of £6 16s. 11d.

SOCIÉTÉ NATIONALE D'HORTICULTURE DE FRANCE.—At the recent and very interesting meeting of the Orchid Committee of the National Horticultural Society of France, we noticed, amongst many fine specimens, a splendid Cattleya Trianae alba, with a fine yellow-coloured throat; Miltonia Warscewickii, with four flower-spikes; Odontoglossum Wilckeanum pallens, and several other plants from M. RAOUT. A cross between Cypripedium Harrisonianum and C. Haynaldianum is particularly successful; the dorsal sepal is pure deep purple, with a white margin. M. PAGE staged C. villosum × C. insigne Chaumont, with very spreading flower, and a very fine variety; C. Lathamianum × C. villosum, the flower of which is the largest we have hitherto seen in this genus. M. GROIX, of the Luxembourg Gardens, showed a new hybrid C. villosum × C. Spicerianum—quite distinct from C. Lathamianum, the flower being all of a pale greyish-yellow colour; C. Zumpka (C. Lecaunum superbum × C. birsutissimum) is worthy of special attention, and gained a Certificate of Merit. M. TRÉFAUST staged splendid varieties of Cliveia and Hippocastrians; and Messrs. Low of Clapton their interesting crested Cliveia, "Bush Hill Pioneer." M. O. DOIN, the well-known amateur grower, has been appointed President of the Committee. G. Traffaut.

NEWSVENDORS' BENEVOLENT AND PROVIDENT INSTITUTION.—We are glad to see that the News-vendors' Benevolent Institution intends to commemorate the present jubilee of the QUEEN'S reign by placing the entire donations received during the year to the Royal Victoria Pension Fund, inaugurated by the QUEEN in 1887, for the benefit of the widows of news-vendors. The festival will be held on Wednesday, April 28, at the Holborn Restaurant, and Lord CREWE has kindly consented to preside.

ONCIDIUM PAPILO ECKHARDTI.—The fine old Butterfly Orchid, Oncidium papillo, although introduced from Trinidad more than seventy years ago, is never plentiful, and a really good-flowered O. p. majus always commands attention. The finest form of the plant is O. p. Eckhardtii, figured in *Lili. Hort.* in 1883, t. 500; and a similar variety was offered for sale by Messrs. PROTHEROE & MORRIS, at their Rooms, on Friday, February 12, the plant realising 75 guineas. The upper segments of the flowers of this plant measured 4½ inches in length, and in colour they were bright orange-red, with a few yellow patches; the broad, declined lateral sepals were also of bright orange-red, barred with yellow; and the labellum was of a clear yellow hue, with a broad, dark orange-red band running round the edge, the margin being yellow.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual general meeting of the members of the above Society will take place at Anderton's Hotel, Fleet Street, E.C., on Monday evening, February 22 next, at 7 o'clock.

THE NATIONAL VIOLA SOCIETY.—The first annual general meeting of the members was held on the 10th inst. at Winchester House, Old Broad Street, E.C., when there was a large attendance. Mr. W. ROBINSON, the president of the society, occupying the chair. A favourable report of the work carried

summer, a sub-committee having been re-appointed to undertake the work in connection with the latter. It was also decided to publish a report of the proceedings of the conference, together with particulars of the result of the trial of *Violas* made last year in the Botanic Gardens, and copies, price 6d. each, may shortly be obtained from Mr. A. J. ROWBERRY, of the Crescent, South Woodford.

EUONYMUS JAPONICUS.—Mr. OUTRAM obligingly sends us, from the Isle of Wight, fruiting specimens of this shrub. The capsule is dull red, and the seed

established 30,000 plants in various places, and anticipates that, after two years, their produce will attain important dimensions. The plant requires very little care or irrigation, and can be grown in places unsuited for other crops. The fibre exhibited was decorticated in a hand-machine invented by M. FAUBE. Messrs. J. PLANTA & Co., Swiss merchants, of Alexandria, who have established a scientific experimental cotton plantation near Zagazig, on which sixty different cultivations are being made, exhibited some of the results of their enterprise in an artistic kiosk, where every detail connected with the plant could be studied.

FIG. 35.—*EUPHORBIA (POINSETTIA) PULCHERRIMA*, AS GROWS AT SANTA BARBARA, CALIFORNIA. (SEE P. 121)

out by the society during its first year, together with a balance-sheet, showing that the society had been able to meet all expenses and carry forward a small balance, was adopted. The following officers were re-elected for the ensuing year, Mr. W. ROBINSON, president; Dr. SHACKLETON, chairman of committee; Mr. H. A. NEEDS, hon. treasurer; Mr. A. J. ROWBERRY, hon. secretary; while Messrs. G. JORDAN, of Regent's Park, and J. MORGAN, of Victoria Park, were elected to fill two vacancies on the committee. It was decided, subject to arrangement with the council of the Royal Botanic Society, to hold a show and conference in the society's gardens, and also carry out another trial of *Violas* during the coming

year, a sub-committee having been re-appointed to undertake the work in connection with the latter. It was also decided to publish a report of the proceedings of the conference, together with particulars of the result of the trial of *Violas* made last year in the Botanic Gardens, and copies, price 6d. each, may shortly be obtained from Mr. A. J. ROWBERRY, of the Crescent, South Woodford.

HORTICULTURAL EXHIBITION AT CAIRO.—The Second Annual Horticultural Exhibition was opened on the 22nd ult. by the KHEDIVE. This year an agricultural department has been added, comprising exhibits of food, forage, textile and dyeing products from all parts of Egypt. A novelty was specimens of bagging and fine canvas made from the fibre of the Sisal Agave, the cultivation of which has lately been introduced by Mr. E. A. FLOYER, who has

Their first annual report, just published in English and French, is extremely interesting and instructive to cotton growers. The prisons department showed a large collection of ornamental *herbariums* and window-boxes made by the convicts. For these the low price of 6s. to 7s. procured a prompt sale. The display of vegetables, chiefly by natives and the youths of the Agricultural College, was very fine, and contained some wonderful specimens, grown to a considerable extent from imported English seeds, for which a good demand has sprung up. The Finance Ministry's nursery garden at Ghazirah is an active agent in cultivating and distributing economic plants. Immediately after the exhibition it received applications for 5,000

young trees from native cultivators. The show of better, vying with the best descriptions produced in Europe, was remarkable as representing an industry dating from only three or four years back.

HORTICULTURAL CLUB.—The twenty-second annual dinner took place on Tuesday last; the chair being occupied by Sir J. T. D. LLEWELLYN, Bart., M.P., and there was a large attendance of members and their friends. Messrs. Egleton, Salmon, and H. Wright, of Chiswick, were the special guests of the Club. Amongst those present were the Hon. W. Wilks and J. H. Pemberton, Messrs. Walker, Williams, Bunyard, A. Bunyard, Peter Kay, C. E. Shea, James A. Laing, Harrison Weir, E. Cockett, G. Paul, G. Monro, Gurney Randall, W. B. Hensley, G. Nicholson, &c. The toast of "Her Majesty" was proposed by the chairman, and received with acclamation. Sir J. Llewellyn also proposed the toast of "Prosperity to the Club," which was responded to by the Secretary; that of "The Royal Horticultural Society" was proposed by Mr. Geo. Paul, and responded to by Mr. C. E. Shea; the toast of "The Visitors" was proposed by Mr. Cockett, and responded to by Mr. Salmon, and Mr. J. Wright of the *Journal of Horticulture*. Mr. Geo. Bunyard proposed the health of the Chairman, who, he said, had come away from his Parliamentary duties on purpose to be present. Mr. Geo. Bunyard had kindly arranged for the selection of songs given by the brothers Lamb, while Mr. H. Turner and Mr. A. Bunyard contributed to the musical entertainment of the members.

NOTES ON THE NARCISSUS.

CULTIVATION UNDER GLASS.—Among the characteristics which has given to the Narcissus—or Daffodil, if we follow the fashion, and apply the latter name to the entire genus—the premiership among hardy bulbs, is that of its very long season of bloom. It is scarcely scientific to say that what brings it into flower is absence of cold rather than presence of warmth, but every grower will readily understand my meaning. It commonly happens that very early in the year—as, for instance, in the first week of this present February—the first Daffodils are some inches above ground, and in visible bud, so that a certain amount of bloom may be looked for before March. Then, perhaps, a spell of frost supervenes, and holds these buds absolutely in *stata quo*, uninjured, but inert, for six or seven weeks, and the first flowers are scarcely gathered until April. Now, the mere exclusion of frost by the glass of a cold-house, or the veriest minimum of firing, will counteract the whole of this check, while a moderate forcing temperature will give us the earlier Daffodils in January. If, therefore, we begin with such kinds as Golden Spur, Horsfieldi, and Poeticus ornatus, under glass at the new year, and end with the double or Gardenia-flowered Poeticus out of doors in May—sometimes late in May—it is but a small exaggeration to say that we may have a succession of Daffodils for half the year, and in a far more interesting variety than is afforded by the Hyacinth, or even the Tulip.

To grow the Narcissus to perfection under glass, undoubtedly the first condition is to pot the bulbs early. This applies to batches not required until February or March (and indeed to the outdoor plantations), quite as much as to those from which flowers are expected in January. The Narcissus demands ample time for its rooting, a fact too often ignored. I often wonder who are the deluded folk who buy from the clearance lists advertised in January or even February—dates at which the bulbs in my garden have mostly been underground five months or more, and are often showing strong foliage. All the bulbs should be potted by the first week in September, and I consider the latter half of August preferable. It is difficult to obtain them so soon from the trade—although an improvement in this respect is being made yearly, in response to the increasing demand; therefore, it is safest to grow one's own stocks. Bulbs lifted at the end of June, and stored in a cool, dry place, will be in excellent order for potting in August. Daffodils are

not very fastidious as to soil, provided it be sweet and fairly substantial. I use the stiff loam of my neighbourhood, with an admixture of a full third of leaf-mould and a small proportion of bonfire-ash; sand is not requisite. Pure bone-flour, at the rate of a 4-sized potato to every bushel of soil, will be found advantageous, especially if the bulbs are to be flowered twice in the same pots. Seven-inch pots will be found the best size; they will take four or five bulbs of the largest varieties, such as Emperor, Empress, &c., and from six to nine of the smaller kinds. Experience shows that it is well to set the bulbs rather deeper than Hyacinths or Tulips, and that less drainage is required, one piece of crock and a layer of moss being sufficient, as Daffodils like the soil below them to be kept moist. It is very important not to fill the pot to the rim, as copious waterings will be requisite when the plants are in full growth. The bulbs should be set upon tolerably loose soil, and the whole made very firm by pressure from above the bulbs when the pot is full. The soil should be only just moist, and no water must be given at the time of planting. It is my practice to stand the pots on a level bed of coal ashes, and to mound up every pot with a handful or two of the compost before covering them with 5 or 6 inches of ashes. This keeps the soil and the shoots clean, and can readily be touched off with a pointed stick when the pots are taken out. They will be ready for removal early in December, but if the weather is mild and wet, an examination should be made occasionally to see whether the shoots are appearing. It is well to uncover them as soon as the points appear at all, but no material harm is done should they have grown to the length even of 2 or 3 inches. Such blanched shoots are, however, very brittle, and greater care must be taken in moving the pots. They should never be taken at once into forcing-heat, but should pass through at least one intermediate temperature until the foliage is green, and has made some little growth. Where this precaution has been taken, Daffodils will bear a strong heat for a short final stage. Where a large number are grown it will be found convenient to pack them into a cold-frame, and bring them on in successive batches. Kinds, such as Poeticus ornatus, of which the bulbs are now so cheap that they may be thrown away after flowering, will yield fairly good bloom for cutting if packed closely together in boxes, after the fashion of Van Thol Tulips. From the appearance of the flower-buds onwards, Daffodils can scarcely have too much water; and if grown alone, or with such plants as it will not injure, a liberal daily syringing will help the flowers to swell to the largest size. The tests of really good cultivation are large flowers and short foliage. Drawn foliage not only spoils the appearance of the plants, but makes it difficult to keep choice kinds in vigour for another year. On this point it may be noted that it is possible to flower the bulbs really well another year in the same pots, if the following simple directions are carried out. When the last flowers are cut or past, put one stick to each pot, and tie the foliage to it securely, and closely enough to prevent damage by wind, and stand the pots quite closely together on ashes or a hard bottom. Keep them abundantly supplied with water until the foliage begins to turn yellow, after which they may be left dry and stacked together on their sides until August. Give them one thorough soaking, let them drain for a few days until only fairly moist, and they may then be covered with ashes as before. The second season the same care should be taken of them after flowering, but the bulbs when dried off should be separated and planted out in nursery-beds to recover.

For hard forcing a choice should be made of those varieties only which are stout of petal and moderately short in the stalk. Probably the common Double Yellow, still unsurpassed for earliness and richness of colour when bunched, Tenby, Golden Spur, Horsfieldi, and ornatus are forced in far larger quantities than any others. In a low temperature the choicer and more expensive kinds, and many of the somewhat flimsier, taller varieties of *N. incomparabilis* are available. The white trumpets, albicans, Anicus,

&c., and the Leelsi section, such as *Minnie Hume*, are of exquisite purity and delicacy thus grown. But the amateur—for whom these notes are written—will doubtless have his own favourites. The May-flowering double Poeticus entirely declines to be forced, but the dealers tell me that their customers commonly buy it for forcing, and after the necessary failure, complain of the bad quality of the bulbs. *G. H. Engleheart.*

FARMERS AND ASSESSMENTS TO LOCAL RATES.

In last week's issue we alluded to the publication of a leaflet by the Board of Agriculture dealing with the subject of assessment of land and buildings as affecting farmers, market gardeners, and others, and we now reprint the leaflet in full.

"The Board of Agriculture have, on more than one occasion, found it useful to circulate a memorandum, prepared by the Local Government Board, directing the attention of occupiers of land in England and Wales to the principles upon which assessments are made to the poor rates and other local rates, and explaining the steps which may be taken, where an assessment is objected to, to obtain a reduction of the amount on the ground that their premises have been valued at too high a figure, or the valuation maintained at a level above the actual value.

It has now been thought desirable to incorporate in that memorandum, in addition to the primary subjects dealt with, a reference to the bearing of the Agricultural Rates Act, 1896, whereby special and important provisions relating to the assessment and rating of agricultural land have been enacted. The leaflet now reprinted has therefore been revised in respect of the third part of the memorandum in question so as to set out the later alterations as regards the liability of occupiers of land not occupied by buildings to local rates in the five years commencing April 1, 1897.

MEMORANDUM.

OUTSIDE OF London the basis for the assessment of the poor rate, and practically of every other local rate level under the general law, is, where the Union Assessment Acts are in force, the valuation list made under those Acts. There are only ten places in England and Wales, outside London, where the Union Assessment Acts are not in force.*

1. *As to the Poor Rate.*—The poor rate is assessed upon the net annual, or rateable, value of premises, as fixed by the valuation list. The rateable value is arrived at by making certain deductions from the gross or unimproved value of the premises, which is the rent at which the property might reasonably be expected to let from year to year, if the tenant paid all usual tenant's rates and taxes, and title rent-charge, if any. It is not necessarily the same as the rent actually paid for the property.

The deductions to be made from the gross estimated rent in order to arrive at the rateable value, are the probable average annual cost of the repairs and insurance, and any other expenses that may be necessary to maintain the property in a state to command a rent equal to the gross estimated rent.

If a person considers that his assessment to the poor rate is too high, he must, in the first place, give notice to the assessment committee and to the overseers that he objects to the valuation list on which the rate is based. The notice must be in writing, and must specify the grounds of the objection. It may be served on the assessment committee by being left at the office of the clerk to the board of guardians, or sent by post addressed to the committee at such clerk's office, or delivered personally to the clerk of the assessment committee (i.e., the clerk to the guardians) or at his usual place of abode.

On notice of the objection being given, a day will be appointed by the assessment committee for the hearing of the objection, and on such hearing the committee have full power to call for and amend the valuation list. If they do amend it, they must give notice of the amendment to the overseers, who are to increase or alter the poor rate current at the date of the notice of objection; so that, if on the hearing of an objection made by a farmer or other person against his assessment, the assessment committee reduce the assessment, the objector will only be called upon to pay on the reduced amount the rate current at the time when he made his objection. The reduction will take effect also as regards any rate made subsequently.

Supposing that the objector fails to obtain from the committee such relief in the matter as he considers he is entitled to, the only course open to him is to appeal to the next practicable special or quarter session against the poor rate.

* These places are the parishes of Alverstoke, Bournemouth, Faversham, Birmingham, East Stratton, Liverpool, and Stoke Newington; the Township of Manchester; and the Poor Law Incorporations of Kingston-on-Hull, Plymouth and Southampton.

He cannot appeal against the rate unless he has first objected to the valuation list in the manner above referred to, and has failed to obtain relief from the assessment committee.

If he appeals against the rate he must give twenty-one days' notice in writing previous to the holding of the sessions to which the appeal is to be made, of his intention to appeal, and the grounds thereof, to the assessment committee and the overseers.

On notices on the hearing of an appeal against the poor rate are empowered to amend the rate by altering the sum therein charged on any person, or in any other manner which may be necessary for giving such relief as they think just; and in certain cases they may quash the rate. If the rate is quashed, the valuation list must be altered by the assessment committee in conformity with the amendment.

If the decision of the justices in special sessions is against the appellant, he may carry the appeal to general or quarter sessions. But in the vast majority of instances in which persons who have been over-assessed take action in order to get their assessment reduced, no appeal against the poor rate is necessary; the relief desired is obtained by the simple process of objection to the valuation list before the assessment committee.

With respect to places in which the General Assessment Acts are in force, it may be stated generally that subject to the provisions of any local Act, the procedure for obtaining a reduction of assessment is by appeal against the poor rate to special or quarter sessions.

II. As to Rates other than the Poor Rate.—The principal rates other than the poor rate which are levied under the general law, are the borough rate, the county rate, the highway rate, the general district rate, and certain rates levied for sanitary purposes in rural districts.

When the whole parish is liable to contribute to the borough rate or county rate, the sum required is paid out of the poor rate. Where only part of the parish is liable, a separate rate is levied in such part in the same manner as the poor rate, and the same observation applies to sums required for the expenses of school boards and burial boards. All these rates are based practically on the valuation list; and it would seem that if the assessment committee amend the valuation list by altering the objects of the list, any of these other rates should be correspondingly amended without any formal appeal against it.

As regards the highway rate, it is expressly provided that where any valuation list has been amended by the assessment committee on objection, the committee shall give notice of such amendment to the surveyor of highways, or other person authorised to make and levy the highway rate, who shall thereupon alter the then current highway rate accordingly.

As regards the general district rate levied by an urban authority, it has been held by the Queen's Bench Division of the High Court of Justice that where, subsequent to the making and demand of a general district rate, the valuation list upon which the rate was based was amended by the assessment committee by the reduction of the assessment of particular premises, there was shown, upon a summons for non-payment of the full amount of the rate as assessed upon the premises, sufficient cause for non-payment of so much as the rate as so assessed on the amount of rateable value in excess of that to which the assessment committee had reduced the assessment, although there had been no appeal against the general district rate.

The urban authority are empowered to reduce the sum at which any person has been assessed in the rate, if he has been over-rated, i.e., if he has been assessed on a higher rateable value than that entered in the valuation list in respect of his property.

If a person assessed in any of the above rates considers that he is over-rated, and is unable, in any other way, to obtain such relief as he considers himself entitled to, he may appeal against the rate.

In the case of a highway rate, he may appeal to the justices at the next practicable general or quarter sessions. For the purposes of such an appeal, notice in writing must, within fourteen days after the making of the rate, be given to the surveyor of highways, warden, or urban authority, as the case may be, of the intention to appeal, and the notice must be accompanied by a statement of the grounds of appeal.

On the hearing of the appeal, the justices may amend or, if necessary, quash the rate.

An appeal against a general district rate lies to the next court of quarter sessions held not less than twenty-one days after the demand of the rate. Fourteen days' notice of the appeal must be given to the urban authority, and the notice must state the grounds of appeal.

In the case of separate rates levied by overseers to meet expenses of rural districts, the same appeal lies to special or quarter sessions, as in the case of the poor rate.

Separate borough rates and separate rates to meet contributions required by a county council, may be appealed against in like manner as a poor rate, and the same remark applies to separate rates to meet the expenses of a school board.

Appeals against rates levied under the Lighting and Watching Act, may be made to general or quarter sessions, subject to the same provisions as appeals against poor rates.

III. Reduced Rates in respect of Land not occupied by Buildings.—Occupiers of land used as arable, meadow, or pasture ground only, or as woods, lands, allotments, or gardens, market gardens, or other grounds, are, as provided by a general district rate in an urban district in respect of such land, in the proportion of one-fourth part only of the rateable

value according to the valuation list; and in the case of a separate rate for special sanitary expenses in a rural district they are, according to circumstances, either to be assessed in respect of one-fourth part only of the rateable value of the land, or to pay in respect of it one-fourth part only of the rate in the pound payable in respect of houses and other property.

Occupiers of houses, buildings, and property (other than land) are required to pay, in respect of their assessment to a lighting rate under the Lighting and Watching Act, a sum in the pound three times that paid by occupiers of land. So that, if the rate on other property is 6d. in the pound, occupiers of land have to pay only 2d. in the pound.

Failure, in rating such occupiers, to allow the partial exemption for which the Acts provide, would be a good ground of appeal against any of the three rates above mentioned.

2. In the case of rates which the occupier of agricultural land has hitherto paid in full, or in the proportion of more than half, he will during the five years commencing on April 1, 1897, be liable to pay one-half only of the rate in the pound payable on buildings and other hereditaments. This partial exemption will, however, not apply to rates assessed under any commission of sewers or in respect of any drainage, wall, embankment, or other work for the benefit of the land. The expression "agricultural land" means any land used as arable, meadow, or pasture ground only, cottage gardens ex-

clude almost sure to give some trouble now and onwards, and precautions must therefore be taken in time. There are few forced plants which are more easily ruined by neglect than Roses; they cannot withstand severe fluctuations in temperature, in the quantity of water afforded, or the amount of air admitted to them. As regards means for killing insect enemies of the Rose, all insecticides are of about equal merit, and equal efficiency in competent hands, and all are almost equally dangerous when used indiscriminately. The main points are prompt application, and weak solutions freely used. Too often the amateur is under the impression that a mixture was not of sufficient strength, simply because a few insects can still be seen alive after the plants have been syringed, forgetting that to use the mixture strong enough to immediately kill the insects is a sure way of crippling the tender growths more or less. A weak mixture freely used will accomplish all that is necessary without injuring the plants. I keep a very weak solution in frequent use from the first, even before a single aphid is visible. Fumigation for Roses is not to be recommended, excepting the plants have got thoroughly infested with insects, in which event, and if the growth is much advanced, it is impossible to reach them with washes amount so much foliage. In that case a weak fumigation should be kept up for several hours, that is longer than is the general practice. The morning after the fumigation the plants should be freely syringed with a weak mixture of insecticide and water, and a weak fumigation again given the house the next evening. There is no method of killing thrips, red-spider, and aphid long established at a single dressing without checking injuriously the new growths. In almost all cases of crippled shoots and loss of flower-buds, it is caused by too severe measures in combating insects. An equally important matter is root-watering, for if a plant be once allowed to become over-dry, mildew is almost certain to attack it, especially if growth be checked also by inattention to ventilation and beating. As proof of this, it may be noticed that plants in the open are similarly affected injuriously by the changes in the weather. With care, and the regular use of a very weak solution of mildew-killer, mildew seldom does much harm. Flowers-of-sulphur, however well applied alone, is more or less unobtainable; but add 1 tablespoonful to 1 gallon of some kind of weak insecticide, and syringe the plants, and it is not unobtainable if it be kept well stirred during use. This gives an even yet slight dusting of sulphur over the leaves on both sides, and its presence will scarcely be observed. Most commercial insecticides contain some amount of sulphur, but few have sufficient to be active as against mildew. Liquid-manure in a weak state should be frequently made use of. Little and often is a good rule for all kinds of manure. Never afford manure-water to very dry soil, but afford pure water first. The soil of Rose-borders should now receive an abundant soaking of weak liquid-manure, and any mulches still remaining should be left untouched for the present. Trained Roses on walls and roofs need the same kind of root-protection as the Grape-vine. Their roots are sure to ramble beyond the border in which they were planted, which should be kept from the action of frost, &c. A. P.

FIG. 36.—NEW FORMS OF ORCHID-POT.

ceeding one-quarter of an acre, market gardens, nursery grounds, orchards, or allotments, but does not include land occupied together with a house as a park, gardens other than as aforesaid, pleasure grounds, or any land kept or preserved mainly or exclusively for purposes of sport or recreation, or land used as a raccourse.

After March 31, 1897, the rateable value of agricultural land is to be stated separately from that of buildings or other hereditaments in the valuation list 4, Whitehall Place, S. W., January, 1897.

Copies of the health acts to be obtained free of charge and post free on application to the Secretary, Board of Agriculture, & Whitehall Place, London, S. W. Letters by Applicants so addressed need not be stamped.

THE ROSARY.

THE ROSE-HOUSE.

WHERE Roses are forced, the present is a critical time, and the gardener must be constantly on his guard against the sudden and wide fluctuations of temperature so frequent during the early spring months. During bright days artificial heat is scarcely needed, but at night and in the early hours of the morning, as well as on sunless days, artificial heat is as much a necessity as it was two months ago. Insects and

NEW INVENTION.

A NEW FORM OF ORCHID-POT.

Our attention has been drawn to a new form of Orchid-pot, devised with a view to secure uniform moisture, complete drainage, and free access of air to the roots. The principle seems to be that of making the basket, pot, or raft of hollowed material, to be filled with water, or sphagnum-moss saturated with water. When this is done, it is assumed that the moisture will at once begin to permeate the porous clay, and thus secure constant moisture and an equal temperature to the roots. How far this will prove an advantage over the usual process of saturation followed by gradual evaporation remains to be seen. The pots, rafts, &c., are made in various shapes, some of which are shown in fig. 36. Mr. A. G. Stollery, of Bushey, is the patentee.

HOME CORRESPONDENCE.

THE ROYAL HORTICULTURAL SOCIETY AND APPLE CLASSIFICATION.—On reading the annual report of the Royal Horticultural Society as published recently in your columns, I was somewhat disappointed not to see mentioned therein the above-named subject. Judging by a letter from Mr. Wilks, the secretary, published in one of your contemporaries a short time since, I felt sure the Council intended to give us their decision on the matter. Surely it is not too late for this to be done before another hardly fruit exhibition comes on. To my mind, the best way to do this would be to appoint a small representative sub-committee, consisting of some of the members of the Fruit Committee. Doubtless their decisions would be acceptable to the main portion of cultivators and exhibitors of hardy fruits, and to those persons who have to arrange prize schedules bearing upon the subject. Without wishing to prejudice the matter in any way, I am of opinion that, for exhibition purposes, two lists (and two only) should be allowed, viz., one for kitchen Apples, and one dessert ditto. For private use, the matter must remain as before, viz., each choosing for himself, whether eating or cooking, or what are now called kitchen or dessert varieties. *H. J. C.*

LECTURES AT THE DRILL HALL.—I hope that a special effort will be made by the lecturers to read their own papers, and not leave it to the Assistant-Secretary of the Society to read them. I certainly think they are not so interesting when they are read second-hand; and I should like to see some members of the Council, or some of the different committees there, to support the chairman, instead of having empty chairs to do duty for them. Some of the lectures during the past year were very tame affairs, and there appeared to be very little interest taken in them by the Council or members of the different committees, which is not very creditable to the leading horticultural society in the country. *John Corbille, F.R.H.S.*

AT CHISWICK.—Most heartily do I endorse the suggestion that there should be a Fellows' meeting at Chiswick during the ensuing summer. At some period when the gardeners look their best would be the fittest for such a gathering. If the visit included an inspection of the various trials being carried on, it would suffice if the meeting began at 2 p.m., and continued well into the evening; so many Fellows could then get through their business, and have a very enjoyable finish to the day. Why should not the council, in commemoration of the great event of the year, hold an "at home" to the Fellows, and to the committees especially? What a delightful function might it prove to be, if carried out with liberality and discretion! Very probably some Saturday would be of all days the best for the purpose. If, as you suggest, the proposed Victorian Medal be then distributed, all very well, provided the ceremony of distribution were short and devoid of formality. Of course, even the desirability of that ceremony would depend on the general acceptance or otherwise of the basis on which the Medals were awarded. I trust they may not be converted into apples of discord. Better a hundred times the proposal be dropped than that their distribution should create jealousies and heart-burnings. The proposed Chiswick gathering could not do that if all Fellows be invited. It would be a pleasant garden-party, affording ample time to see the gardens, to hear the medals to join in free social intercourse, and send all home in the happy assurance that it was good to have been there. *Correspondent.*

CYPRIPEDIUM INSIGNE SANDERÆ.—In your issue of February 6, I am sorry to see that Mr. Ball, commenting on his *Cypridium insigne Sanderæ*, seems to have got rather "mixed." I have also an impression that his reference to a later importation of the plant is very vitally important. I may here remark that I think it would be wrong to name this *Cypridium* the "Eron Schroder" var., inasmuch as it is clearly shown that Mr. Measures had part of the same plant; it therefore simply remains *C. i. Sanderæ*. My knowledge of Mr. Harley's plants extends but very little beyond what he shows publicly. I should not have taken any notice of his remarks had he not said that he never showed his *C. i. Sanderæ*. Allow me to refresh his memory, and ask if the plant with three flowers shown in Messrs. Heath's Orchid group at the Manchester Chrysothamnium show, November 1895, was not his plant, and if it was not labelled *C. i. Sanderæ*, and the name

given as such in the *Gardeners' Chronicle* of November 30, p. 657? also if this was not the same plant he gave £275 for at the Pickering Lodge sale? It was at this show I had the opportunity of comparing very carefully the yellow form shown by Mr. Ball with the one shown by Mr. Harley—hence my comments. *S. S., February 15.*

RIBSTON HA L. NEAR WETHERBY, YORKSHIRE.—As I will be known to many of the readers of the *Gardeners' Chronicle*, it was on this estate that the famous Ribston Pippin Apple originated. It is the property and residence of Major Deet; and Mr. Thomas Jones has been the head gardener there for forty years, having been recommended to the post by Sir Joseph Paxton in 1857, under whom he had served at Chatsworth. During the time he has been at Ribston he has served under three generations of the "Dent" family, and retained their confidence all along. Mr. Jones is retiring from his post, and he has purchased a neat cottage in that small but pretty inland watering-place, Boston Spa, situated a few miles distant from Ribston on the southern side of the river Wharfe. Mr. Jones will carry into his well-earned retirement the good wishes of all who have known him. While his name has not been very prominent in the gardening world, he is not the less done good work, being a sound practical gardener, and in all the varied relations of life a good man. He is succeeded by a Mr. McClelland, late gardener to Colonel Sylvester, near Wigan in Lancashire. *H. J. C.*

VAGARIES OF THE ROSE.—"Wild Rose," whose communication I read in the last issue of the *Gardeners' Chronicle*, will be interested to learn that a bush of *Niphedus* in a private garden in this neighbourhood has recently departed from its normal condition, and assumed the climbing character in a very decided manner. Last season the shoots were thick, numerous, and long, although the plant was originally very weak. The bush has now become one of extraordinary vigour, so that the greenhouse is unequal to contain it, and the shoots have had to be cut back. In my opinion, this fresh instance of variation from the type is more conspicuous than that displayed by the specimen exhibited by Messrs. Keynes, Williams & Co., at a meeting of the Royal Horticultural Society some years since. I shall be curious to note how the bush behaves this season. There is nothing in its surroundings to account for the sudden change of character in this Rose. *W. Roope, Streetham Hill, S.W.* [A reversion to the savage habits of its ancestors. Ed.]

THE GRAPES AT EDINBURGH.—I have been a competitor for thirty years at Edinburgh, and I never heard so much dissatisfaction expressed as at the show last autumn; neither do I wonder at it, when judges gave the best prizes to Grapes neither finished nor yet fit to eat—which is an undeniable fact. In the Black Havour class, *Gros Maroc* was placed 1st, and *Black Hamburgh 2nd*, before several bunches of *Muscata Hamburgh, &c.* A northern gardener seems to think that these bunches were not 1 lb. weight. The smallest I noticed was the *Black Hamburgh*, which was placed 2nd. Be that as it may, there were plenty over 2 lb., and some over 3 lb., so far as I can remember. The schedule says distinctly, all fruit must be ripe and sound, and fit for the table. Why do judges judge fruit without tasting it? Mr. Dixon's letter on this point, and had he been judge at Edinburgh, the prize tickets would, I have no doubt, be differently placed in a good many classes. It seems to me the time has arrived for rules in judging to be applied, also in specifying the varieties wanted. 'The proof of the pudding is the eating o't.' *A Falkirk Gardener.*

LIGUSTRUM CORIACEUM.—With reference to a note inserted in your issue for February 13, on *Ligustrum coriaceum*, which is of Japanese origin, I would remark that many years ago I visited the Metropolitan Convalescent Hospital at Walton-on-Thames, there for the first time in my life saw this beautiful Privet in full bloom. I was so much struck with its bloom that I requested some cuttings might be sent to the Atkinson Morley Convalescent Hospital at Wimbledon, which was done. These cuttings in a year or two grew very well; they were subsequently transplanted, and removed to a long row at the back of the hospital, where every year, in June or July, they have large quantities of white blossoms of some size, utterly unlike our ordinary Privet. They are always the admiration of beholders. I sent other cuttings to a friend of mine, the Vicar of Salsley, in Gloucestershire, but the results there I believe are less satisfactory than at the two former

places, which may, perhaps, arise from the soil not suiting them. They are quite hardy when the roots are established, and I think might be tried in London. This Privet does not seem to me to be a plant of a particularly slow growth. *John Colebrook.* [Is our correspondent sure that the plant he mentions is correctly named? Ed.]

PEAS IN TRENCHES.—This is a question which requires discussion by gardeners. In a communication from Mr. Markham to the *Gardeners' Chronicle*, found on p. 83, there are the following statements:—"For several years I have been a great advocate of trenches in Pea-culture, especially mid-season sowings;" and further on—"Still I have my doubts whether, in a very dry season the crops are as good as would be the case if less manure was used, and the soil made firmer." I would ask, is this generally the case? With me it is quite the reverse; and I understand that sowing in trenches is a greater gain in a dry season than in a wet one, and more especially if the soil be light and porous. I would not advocate sowing Peas in trenches in heavy retentive soils. *J. Mayne, February 8.*

THE SPICE APPLE.—Having made the acquaintance of the true Spice Apple some years since through the veteran Rose-grower, Mr. Benjamin Cant, of Colchester, it has been a great favourite of mine ever since. Now, I specially noticed Mr. Finch's note on flavour in Apples, in *Gardeners' Chronicle* for January 9, p. 27, and had no doubt, from reading Mr. Barron's and his note, that they are writing of the D'Arcy Spice, so called from the hall of that name, near Colchester. In fact, the D'Arcy Spice is one of the most popular and useful of all our late dessert Apples. Being such a good and almost indispensable dessert Apple for April and May, and the fact, too, that several other Apples have a good dash of spiciness in their flavour, it followed almost as a matter of course that several Spice Apples got into commerce, which has caused no little confusion. Yet I would hesitate to call them imposters; on the contrary, the some half-dozen I have met with have all had more or less of spiciness in their flavour, with a dash of Russet, Nonpareil, and Ribston. The Spice of old Chiswick seems different from the Spice of Dr. Hogg's Manual; while both these and the D'Arcy Spice differ from the Spice or Sack of the same authority. The Aromatic Russet is also often commingled with the Spice Apple, and is a dessert Apple of superb quality from December to February. The Hereford Spice, on the contrary, is much higher coloured, and earlier, being in season from October and through January. But as the district round Colchester is undoubtedly the home of the D'Arcy Spice, it is no doubt this very valuable and useful dessert Apple that your correspondent wrote about. As to the hardness and dryness of the flesh that Mr. Barron notes, this depends a good deal on soils and seasons, and when these qualities are not in excess, they are merits rather than defects. We have plenty of soft, juicy Apples for eating, but assuredly not one too many from despatched ones, as perfect Ribstons or Russets, that will keep sweet and sound until May and June. The D'Arcy Spice is also in commerce as the Ribston Spice, the Baleno! Pippin, and the Spring Ribston, having been sent out by the late Thomas Rivers of Sawbridgeworth under that name about 1858, so far as I can remember, though the resemblance is not striking—unless in flavour. But the name of Spring Ribston from such a source, was a very high testimonial as to sterling quality. *D. T. F.*

PRIMULA OBSCURA.—Your correspondent, "R. D.," on p. 65, recommends *P. obscura* to be crossed with *P. Sieboldi*. In 1893, I crossed *P. Sieboldi* crosswise with *P. obscura*, in the hope of raising a variety that would not cause such irritation to the skin of human beings after handling as *P. obscura* does. I selected a well-coloured *P. S.* crosswise for the seed-purist, and I isolated the pollen also carefully removing the anthers from several of the blooms before the pollen formed. I was so much struck with its bloom that I requested some cuttings might be sent to the Atkinson Morley Convalescent Hospital at Wimbledon, which was done. These cuttings in a year or two grew very well; they were subsequently transplanted, and removed to a long row at the back of the hospital, where every year, in June or July, they have large quantities of white blossoms of some size, utterly unlike our ordinary Privet. They are always the admiration of beholders. I sent other cuttings to a friend of mine, the Vicar of Salsley, in Gloucestershire, but the results there I believe are less satisfactory than at the two former

SUTTON'S PRIMULA STELLATA.—Although this year is my first trial of it, I must say that I am highly satisfied with its flowering qualities. I have it growing in 4½-inch pots. The blossoms being gracefully poised on slender foot-stalks in whorls, with stems varying in height from 4 to 12 inches, give the whole plant the appearance of a pyramid, measuring, in some cases, fully 30 inches in circumference. The flowers are white, and sometimes flaked with crimson, and the plant has foliage of a dark green colour and is as a pot-plant for general decoration for the greenhouse and conservatory, this light and graceful Primula should become very popular. A red-coloured variety of this would be a great acquisition. *Alce. McInnes, Edinburg Palace, Edin.*

WHAT BECOMES OF THE RAINFALL?—It may be of interest to note, in reference to the question, "What becomes of the rainfall?" that in consequence of the exceptionally large rainfall during the four last months of the year 1896, amounting to 18 inches of rain, which is equal to the enormous quantity of 1818 tons of water on each acre of land, the springs of water have risen in the wells of the neighbourhood of Harpenden, Hertfordshire, very remarkably. In our unused well from which records of the rise and fall of the water is taken at the end of each two months, it was found that the depth of water rose from 3 feet 8 inches in September to 5 feet 3 inches in November, and to the extraordinary jump of 8 feet 8 inches at the end of January, 1897. The rainfall of January, 1897, according to the 8-inch gauge of Sir John Lawes at Rothamsted, is 1.75 inch, which is about three-quarters of an inch less than the average fall for January in the neighbourhood, extending over a period of forty years. *J. J. Willis, Harpenden.*

CHRYSANTHEMUM SPORTS.—Some time ago I was astonished to see a beautiful green-yellow flower on a plant of the variety Vividum Morel, which had been grown as a bush, and had given a good crop of normally-coloured flowers. Upon examination, I found a shoot had sprung from the neck of the plant a little above the soil. I cut the plant down, and carefully staked up the shoot, and in doing so I found another shoot a little distance from the first, which I shall call No. 2. When both are staked, the plant was stood near the glass. The first one had grown a fair flower under the above circumstances, measuring 7 inches across; the green-yellow has given place to outside petals white, shading to pale yellow centre. No. 2 was a very light shade of Charles Davis in bud, but has finished a light cream, with a tinge of chocolate towards the centre, resembling some of the Tea Roses. I think there can be little doubt but that they will be fixed, as I shall have no difficulty in getting stock from them. I think it is remarkable that two shoots should produce flowers so entirely different from the colour of the parent. *Wm. Kilgour, Elgie Hill Gardens, Aberdeen.*

THE VICTORIA ERA FUND.—Having read with much interest the various proposals to commemorate Her Majesty's long and beneficent reign, which have from time to time appeared in your columns, I venture to make an additional one. I suggest that gardeners and their assistants be asked to contribute a small fixed sum towards a general fund, which should be equally divided between the Royal Benevolent, the Gardeners' Orphan, and the Victorian Era Fund; and if all the gardeners, foremen, and journey-men in the United Kingdom would contribute on the following scale—*6s.* for head-gardeners, *2s. 6d.* for foremen, and *1s.* for journey-men, &c., what a grand sum it would amount to! The sacrifice is so small, that it might be made by everyone. It might be easily managed if head-gardeners would unite and collect in their own gardens and immediate neighbourhood. I think that, as a rule, gardeners are as loyal and charitable body of men as any, and I think it is a duty to make a special effort this year to do something that will tend to remove the reproach that a collector so often hears made, "Why don't the gardeners themselves do more to assist these charities, especially as they and their families, only reap the benefits." Did they do so, I think our employers would be more ready to help these most deserving charities. *F. Harris, Easthor.*

THUYA Plicata AND T. OCCIDENTALIS.—I quite fail to understand how anyone who has studied living specimens of these trees growing in this country can say that *T. plicata* is a variety of *T. occidentalis*. Since reading your article I went purposely and examined a tree of *T. plicata*, 18 feet high,

and compared both foliage and cones with those of *T. occidentalis*, of about the same size, growing a short distance away. The very unpleasant smell emitted by the foliage of *T. occidentalis*, the loose, open habit, long, lithe, and scantly-foliaged branches, and small sub-erect cones, 180,000 seeds of which go to the pound weight, are marked characteristics. Then, the foliage always turns of a dirty bronzy hue in winter. *T. plicata*, on the other hand, has not the least unpleasant smell, is always compact of growth, though not formally so, with short, stout, rather ascending branches, that are well furnished with flattened leycopied-like foliage, while the plentifully-produced cones stand quite erect, with small and light seeds, 245,000 going to the pound weight. In winter this tree never turns bronzy, but rather a dark yellowish-green colour. If *T. plicata* must be a variety I would refer it to *T. gigantea*, with which in every respect it is far more nearly related than with *T. occidentalis*. *J. D. Webster.* [Are there two *plicatas* in cultivation? The story is not yet ended. Ed.]

CLIMBING ETIENNE LEVET ROSE.—I have read with pleasure an article by "Wild Rose" on "The Vagaries of the Rose;" but I am surprised to see that he does not know of the strong-growing ordinating form of the *Etienne Levet*, which has been cultivated for centuries ten or twelve years. It is not as yet common in gardens, and it did not originate in this neighbourhood. When treated and pruned as a cut-back, you would scarcely tell the difference between it and the type, except that the growths are slightly stronger; and there is, as "Wild Rose" remarks, no difference to be seen in the flowers; but immediately the first flowers have bloomed, it throws up strong sucker-like growths from the base, that reach a height of 4 to 6 feet, which very seldom flower in the autumn. Neither has "Wild Rose" mentioned Climbing Victor Verdier and Climbing Henri Ledehaux, which I consider are two of the prettiest climbing hybrid perpetuals we possess. In both these varieties the flowers are smaller than their types, and produced in great profusion. I would not trouble you with this if I knew who "Wild Rose" is; but I was interested in his article, and imagined I could add to his knowledge of the subject on which he wrote. *Henry Merryweather, Jun., Southwell, Notts.* [We are very thankful for such notes; and so is "Wild Rose." Ed.]

THE CLIMBING VARIETIES OF FRENCH BEAN.—At this season, when gardeners are sending their orders for seeds, &c., to the nursery and seedsmen, I think it right to call attention to the merits of the climbing French Beans. My experience of these Beans last summer was that no kind of kidney bean withstood drought and heat so well; and the varieties which I grew were Epicure and Tender-True. Our Scarlet Runner Beans set few flowers, and were, besides, eaten-up with red-spider; whereas the new Beans had healthy leaves and bines, and supplied nice crisp pods. *R. M. Newbury.*

CEDRUS DEODARA FAR NORTH.—All the *Cedrus Cedrus* I have seen in this district seem to do well in fully exposed situations. It is a species not much planted as a forest tree. This place stands on a hill, with full exposure to the North, and to the winds which come down the Gallopden valley. There were several *Deodars* planted eight years ago on the lawn, which have withstood exposure quite as well as any Scotch Fir could do. *R. Macdonald, The Gardens, Drummond Hill, Inverness.*

GLADIOLUS HYBRIDS.—Having been engaged for some years in raising Gladioli from seeds, obtained by crossing such species and varieties that I have been enabled to induce to flower at the same time, I read with interest the remarks made by Mr. Douglas (*ant. Chron.*, Jan. 9, p. 17), in which he urges upon gardeners the importance of taking up the work of hybridising. In this I agree with him perfectly; but having had experiences, I am also aware that the matter is not so easy as might be supposed. In the first place, showy species, likely to give good results when crossed with those we now have, are not easy to obtain, and many of those obtained do not prove so easy to cultivate, or to flower, as do those at present in gardens. Five years ago I got Gladioli Lind-wich, which appeared to be very distinct and robust, judging by the strong, ribbed foliage which it produced the first year. It, however, failed to flower, and the second year it would not even grow. In 1895, I bought *G. oppositiflorus*, described as being a white variety, and a very strong grower, even up to 6 feet in height. However, I lost it; but thinking it was just what I wanted, I got it again in 1896. This time, thinking it had previously been killed by

cold, I potted it, and at the same time a batch also of *G. Childii*, all being planted in rich soil in June, and well watered and cared for. The latter bloomed well, but *G. oppositiflorus* never did, and did not make so strong a new corn as the old. I have it now in a very warm place in sand, treating it as I do *Watsonia O'Brienii*, to try and ripen the corns. I shall start both in a gentle bottom-heat to have them ready to go out in May. With regard to the Madagascar record of *G. oppositiflorus*, I think there has never been any confirmation, and even of the Kaffrarian habitat, it is said to be doubtful whether it is indigenous. Of course, the difficulties suggested will not deter me from continuing the work in the best manner that our variable climate will allow; but I would suggest that gardeners or nurserymen in the Cape, Natal, Melbourne, Sydney, and other parts where sunlight and heat are more abundant than with us, should take up the crossing of such hardy species as *G. Sandersii*, *G. purpureo-auratus*, &c., with any showy but more delicate species obtainable, and thus some new races might be obtained, which when sent to us in the mature corn would prove as easy to grow and flower as are the varieties of *G. gandavensis*, though they would be difficult for us to raise in the first place. I have had very satisfactory results with the *Nancionius* and *Lemoinei* hybrids, raising and flowering them very quickly. On March 25, 1896, I sowed seeds from these two varieties, and managed to spare the seed-bed plenty of water, whilst the old balls got none. The result was that we got our best spikes from the seedlings. The first of the batch bloomed early in September, and in spite of the cold and wet, they continued to bloom until the first week in November. *J. O.E.*

FLORISTS' FLOWERS.

PANSIES AND VIOLAS.

With *Viola* and *Pansy* societies around us doing their best to popularise these lovely, and withal sweet garden favourites, one is tempted to ask, "Where is your old correspondent, Mr. Bennett, who had the honour of introducing the progenitor of the *Violas* when he brought out *Viola cornuta* as a bedding plant?" I do not, of course, forget that part of the honour belongs to the late John Willis. By intermixture with the *Pansy*, a hardier plant has been produced, which not only rivals the *Pansy*, but is superior to it as a bedding plant. Few people flower the *Pansy* in pots now, but I do not know any sweeter or more beautiful flower to grow in pots and keep in cold frames during the winter and spring; moreover, they are cheap, and very easy to cultivate. I recommend cuttings to be taken in July for raising plants to grow and bloom in pots. The best cuttings are those which are made from the slender growths growing in the centre of a plant, which usually have some few roots attached to them—set these in boxes in a shady place, and they will readily start into growth; whereas, if the thick flowering stems be taken out at a joint, it requires a longer time to form roots if they do so at all, and they never make sufficiently good plants for pot culture. When the young plants get well established, pot them into 60-size flower pots, and arrange them in a cold-frame on the north side of a wall, or high fence of some kind, the *Pansy* disliking hot sunshine, so that it should not be fully exposed to it. The lights should only be made use of during heavy rain and hail-storms. The plants should be repotted into 6-inch flower-pots as soon as they fill the first pots with roots, using a good rich and open compost of three parts loam, one of decayed-manure, and one of leaf-mould with some sand to keep it open. As the plants increase in growth in the autumn, the flower-buds must be pinched out, and the shoots pegged down on to the soil.

CARNACTIONS AND PICOETES.

The careful amateur will now be making preparations for the re-putting of his Carnations and Picoetes. The compost may consist of one half rotted decayed turfy loam, decayed stable manure and leaf-mould one-fourth each, and coarse white sand enough to give porosity. Some growers for a salutation use artificial manure, and for this purpose I find bone-dust as good a stimulant as any; but I find that it is better to mix it with the compost used as a surface-dressing in

May. The flower-pots, mostly 24's and 16's, should be washed ready for use. The plants should have all dead and decaying leaves removed, and if the weather be dry and mild, the frame lights may be removed. Many growers submit their plants to extreme dryness during the winter; but this is a mistaken practice, as at the beginning of February moisture has become necessary, growth usually recommencing then if the weather be mild. At this season frosty winds are prevalent, and little or scarcely any ventilation is then advisable. If the collection is a small one, the re-potting of the plants may be delayed till the middle of March. Notes should be made of the loss of varieties, so that they may be made good. Some varieties are very scarce, and it will sometimes occur that the stock of plants is sold out by an early date, and it behoves the grower not to delay his orders. No plants should be purchased unless well established in pots, Carnation layers not being successfully transplanted in the spring months. Nothing much can be done for the present with seedlings, excepting in fine weather to stir the soil slightly with a Dutch hoe. When the young leaves develop in the spring, sparrows do much damage—at least, I have never yet had a collection of seedlings that did not require some kind of protection from these birds, such as black thread stretched tightly above the plants.

POLYANTHUSES AND PRIMROSES

of the self and fancy types now become popular. I do not advise growing any of these in pots, as when grown thus they are seldom satisfactory. The plants are quite hardy, and thrive in deep moderately-moist loam, inclining to clay. Seed saved from the blue-flowered varieties cannot be expected to produce every flower quite like the parents, and some have a tendency to revert to pink; and even if the blue varieties are propagated by division, true to name, and grown in pots, the blue tints will, in some instances, change to pink. Therefore, for every purpose let them all have good position, slightly shaded if possible, and in moist soil, where they cannot suffer from drought in summer. *J. Douglas.*

NURSERY NOTES.

"DICKSONS OF CHESTER."

ONE sunny morning early in August last the writer in company with two horticultural friends and fellow-jurges engaged in making the awards at the great Chester show the previous day, visited Messrs. Dicksons famous nurseries and enjoyed a long-deferred pleasure, at the least as regards myself, the city of Chester having been so long celebrated almost as much for the excellence of the trees, &c., cultivated so extensively and well a short distance outside the municipal boundary as it has been for the picturesque-ness of its old streets and houses.

The main drives, from the nursery entrance near the Chester railway station until that at Upton, about two miles further away, is reached, are flanked on either side by handsome specimen Conifers of different species and varieties and dimensions. The avenue which leads to the office, &c., from near the railway-station is imposing, and the well-filled borders on either side afford capital facilities for visitors to inspect the sorts of bedding-plants, which included at the time of our visit fine types of double and single-flowered tuberous-rooted Begonias.

Some idea may be formed of the extent of these nurseries when I state that between 400 and 500 acres of land are occupied by forest and other trees, herbaceous perennials, and other plants. The work in each department is carried on, as is usual in such large concerns, under the supervision of specialists; and a visit is especially interesting to a gardener if made during the summer and early autumn months, when the trees and plants are in full growth, and their characteristics readily observed. Trees and shrubs are frequently transplanted, and set out at wide distances apart, so as to develop fully, and form well-furnished examples, and which

can be safely transplanted at the proper time in any part of the country.

ROSES are largely grown here, about 45,000 Briars being the number that are budded annually; whilst about 250,000 dwarfs are worked upon the Manetti stock.

About 100 acres of land are occupied by fruit trees, and stocks upon which to work them, the trees being transplanted annually. The land is fully exposed to the winds which blow from the Welsh hills, and necessarily make short-jointed, well-consolidated growth, furnished with abundance of small feeding roots and fruit-buds. Such trees, when properly planted in gardens and orchards having a soil of average depth and fertility, go ahead, and within a space of a few years yield profitable returns. The land is laid out in plots of various sizes, well filled with numerous kinds and varieties of trees, shrubs, including Conifers in great variety, &c., ranging from the seedling and cutting stage upwards, all well and skilfully grown.

Dotted about in proximity to the various drives running through the nursery are handsome specimens of diverse trees and shrubs of an ornamental character, and beautiful either in contour, in foliage, or flower.

Facing the office is located an extensive and excellent collection of herbaceous perennial plants, which in August were in fine condition. It was the right season to inspect such plants, but should be preceded by others in April and June by anyone who intends to form herbaceous beds and borders.

On the other side of the avenue, and close to several ranges of glasshouses, were noted some well-filled flower-beds, that afforded visitors to the nursery much useful information as regards the question, "what kind of plants should be employed in filling flower-beds with a view to securing a satisfactory combination of distinct and pleasing shades of colour during the summer and autumn months?"

The glasshouses are well arranged and extensive, and contain many species and varieties of plants, clean and well-grown. I observed among others, Palms, Tree and other Ferns, Orchids, Eucharisas, brightly-coloured Cactuses and Dracenas, Bouvardias, Camellias, and Azalea indica. Mention should be made of the Pot-Vines, some 2000 in number, clean, vigorous, short-jointed, with filbert-like buds in the axils of the leaves, excellent for fruiting in pots or planting in borders. In the frame-ground a long, narrow tank is constructed about 1 foot above the ground-line, divided in several places, in which species and varieties of Nymphaeas are cultivated, a convenient arrangement that enables buyers to make their own selections. In the extensive collection of Carnations were noticed a fine lot of plants of the popular Mrs. Reynolds Hole, introduced by the Messrs. Dicksons in 1887. *H. W. W.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 9.—*President:* Dr. M. T. Masters in the chair; *Rev. W. Wilks, Mr. Shea, Mr. McLachlan, and Rev. G. Henslow, Hon. Sec.*

Cedrus and *Ficus*.—Dr. Masters exhibited specimens of Decid. Larch, and Cedar of Lebanon, grown by Mr. J. Simpson at Wharfedale. They were said to have been planted at the same time, about thirty years ago. It was remarkable that the heart-wood of the Larch and Decid. were much alike, while that of the Cedar was different, in not being so darkly coloured like the others. The quality was in each case good, especially that of the Larch. It has been observed by Dr. Tristram that the wood of the Cedars grown on Mount Lebanon is much closer in grain and darker in colour than that of trees grown in England (*The Nat. Hist. of the Bible*, p. 43).

Spines of Plants.—Dr. Masters also exhibited specimens from Mr. P. D. Webster and others, illustrative of the confusion in the nomenclature of this genus. He observed that *T. occidentalis* grows in the Atlantic States of North America, and *T. gigantea* (Lobbi) in the north-western or Pacific side. A form, originally named *T. pleiata* was introduced at the end of the last century by Messrs. Fourn. & Vancouvey, in Deane's *Catalogue of the Plants of the Botanic Gardens at Chelsea*; this plant is recorded, but without description. As this is a western species, it is really synonymous with, or at most, a variety of what is now

generally called *T. gigantea*. But the original *T. pleiata* having probably died out, the name has now become transferred to a form or variety of *T. occidentalis* from the Atlantic side of the United States. It is probable that both species are represented by a "pleiata" variety, but it is not certain whether the Pacific variety is now in cultivation. Specimens of the one plant from Vancouver are in the Herbarium of the British Museum, so that it is a question whether, strictly speaking, the name *T. gigantea* should not be superseded by that of *T. pleiata*. The plant now bearing that name should then be called *T. occidentalis* in place of *T. gigantea*.

Stool Fibre.—A sample of this fibre, extracted from Agave sisalana, was received from Mr. W. Floyer, of Bismarck. It was grown at the experimental farm at Mualla, near Luxor, by Mr. E. A. Floyer, of Cairo. He hopes to grow enough to supply all the bags for Egyptian Sugar, Cotton, &c. The fibre is very white, and extremely strong. The Governor of Malta is anxious to induce the cultivation of this Agave into that island; but as the unutilized parts consist of hard, exposed rock, it is doubtful if it would pay, even if the climate prove suitable. The name was given to the fibre imported from Yucatan. (*Acad. Bull. of Mex. Inform.*, March, 1887.)

HORTICULTURAL MEETING AT GHENT.

FEBRUARY 7.—At the meeting of the Chambre Syndicale des Horticulteurs Belges held on the above date, M. JULES HEVE showed a good selection of his finest hybrid *Cypripediums*; also *Dendrobium Leechianum*, noble nobilior, and *Bittanforium*, all three well bloomed; *Odontoglossum Copartianum*, a fine variety; *Cymbidium chloracrum giganteum*, *Lolita anceps alba Hyemae*, an excellent variety; *Miltonopsis Blennia*, with two splendid racemes of bloom; *Cypripedium insigne Sanderae* Baron Schroder var.; *Lobelia Cattleya Falls* (C. Downii × *L. crispata*, very beautiful, especially the lip, the coloring of which recalls that of *C. Downii*, although the purple tones of *crispata* are retained); *Lycaste Pedunculata*, with several pretty flowers, and other beautiful plants, helped to make M. HEVE's exhibit a remarkably good one.

M. ED. PYSNARR showed a very vigorous *Cypripedium Luthianum inversum* (villosum × *Spicerianum*), with many splendid blooms; M. JULES DE COCK had *C. chaubertianum*, with two fine flower-spikes; *Lithium TIBETICUM INTERNATIONALE*, Brussels, showed *Catylonia Trianae* Imperator, which has been figured in *Gardener*.

In addition to the Orchids, other fine plants were exhibited; M. CAPITAINE sent *Clivia*, *Alice Capitaine*, a new variety, with a truss of bloom nearly 12 inches across; well arranged, the flowers a bright and brilliant colour; M. BIGNOTTI showed *Siphonidium stratum*, admirably grown; M. L. DE SWERTZ-DUYVER, Grooten Hangenberg, with leaves very long spreading, of deep colour and well grown; M. POLLMAN-MAENHOUT, *Vriesea punctulata*; Messrs. Hutton Low & Co., Ceylanum Bush Hill Place, with flowers glisteringly white, and its many crests of the same pure white. M. ED. PYSNARR showed a hybrid between *Flemis tremula* and *P. serrulata*, called *P. Boultoni*, a good form, for whose introduction he is indebted to the late M. de Buxse; and M. BIGNOTTI sent *Clivia* *Bailloni*, Fournier, well grown.

At the General Assembly of the Chambre the proceedings of the preceding year were discussed. At the banquet following, the President, M. ED. BEVIS OCT. BUNNELL, was presented with his own portrait painted by LEON HEENO. This compliment was in recognition of M. BUNNELL's promotion to the grade of an Officer of the Order of Leopold, and of his services to horticulture in general and the Chamber in particular. *Ch. De B.*

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

FEBRUARY 8. The fortnightly meeting of the above Association was held on Monday. The lecture for the evening was on "Soils and their fertility," given by Mr. DRUMMOND A. GILCHRIST, B.Sc., Edinburgh, Director of the Agricultural Department, University Extension College, Reading. Mr. Gilchrist said that before he commenced his lecture proper, he would like to direct attention to the geological map of the British Isles, showing the variations in soils, and the character of the soils derived from different formations. He also remarked upon the climatic conditions in the different parts of the country, and how different plants required different conditions of climate. Taking up his subject proper, "Soils and their Comparative Fertility," he lectured upon the fertility of soils, and the influence of its dissolved parts upon the natural or inherent fertility and artificial fertility. The following were indications of natural fertility. The character of the general vegetation of a district, such as the trees and hedges; for instance, where the Ash is to be found doing well the soil would generally be of a strong loamy nature, and the sub-soil damp; whilst oak, hick, and white formations the Birch would predominate. Trees also (especially isolated trees) are generally indicated whether storms are prevalent in the district, as they showed by their stunted growth or otherwise (whether they had been subject to rough winds in the past). A good Thorn hedge showed that the soil was exceedingly fertile, and the orchards in which farmers cultivated their land the nature of the soil could easily be known, for when the land is laid out in high ridges, it generally indicates

a cold wet soil. The heritage of common land generally indicated whether the soil is fertile or not. Then the colour of the soil and the character of the soil and subsoil, which may be seen at the edge of a ditch, give a good indication of natural fertility or otherwise. Soils in order to be fertile, must have all the ingredients of a plant-food present in a suitable form; they must also be in a suitable condition as far as tilth is concerned. Digging or ploughing, or especially trenching, when carried out on a rather heavy soil or subsoil, when wet, frequently does considerable harm for years by causing the soil to "bake." This should be avoided by carrying out these operations on the heavier class of soils only when they are sufficiently dry. There must also be no injurious ingredients present in the soil.

The dealing with the plant-food in the soil, and the condition in which it should be present, the lecturer dealt with the problem of how the plant-food of the soil could be effectually retained in the soil or even increased, and then discussed how these ingredients could be suitably increased in the soil by the application of various manures. Reference was made to the composition of various local soils which had been analysed in the chemical laboratory of the college. One sample, which was taken from Messrs. Sutton & Sons' trial grounds, showing a useful soil which had been greatly improved by manuring and trenching; which when poor do not band close to the surface, which was very much a poor condition that it would take years to convert into a fairly good soil. Before closing, the lecturer made reference to the work of the earthworms. Darwin was the first to recognise the great work done by the earthworm in improving the soil. Although many would think that the castings caused a great disfigurement to their lawns, yet he could assure them that the worms were greatly improving the soil. Many questions were asked, and a discussion ensued.

SOUTH SHIELDS CHRYSANTHEMUM.

FEBRUARY 12.—The annual meeting of the South Shields and Northern Counties Chrysanthemum Society was held in the Guardians' Offices, South Shields, on Friday evening, February 12. Alderman T. G. MABANE, President, occupied the chair.

Mr. Bernard Cowan, F.R.H.S. (Hon. Secretary) read the annual report, which stated that the balance in hand had been increased from 15s. 5d. to 25s. 5d., which might be considered as highly satisfactory.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 15.—A meeting of the general committee took place on the above date, Mr. B. WYSE in the chair. After the reading of some correspondence,

Mr. C. Harman Payne proposed to rescind a recent resolution of the committee, fixing the hour for commencing the meetings of the Floral Committee at 3 P.M. on all big show days, instead of 2 P.M., as heretofore, but it was lost on a divided vote. The Secretary then submitted a draft report, dealing with the leading incidents of the past year, and setting forth that the Special Jubilee Fund had reached the sum of £370 1s. The financial statement showed that the receipts from all sources amounted to £175 17s. 2d., adding to this a balance of just over £55 at the commencement of 1896, and a sum of £25, which had been added to the Reserve Fund. The total expenditure included an extra gift to the Secretary in respect of additional work occasioned by the Jubilee celebration. There is a sum of £100 on deposit at the bank, and a small balance to the credit of the Reserve Fund. The sum of £83 10s. had been expended on prizes and medals awarded at the various exhibitions. The report and financial statement were received and adopted for presentation at the annual general meeting on the 22nd inst. Eight new members were elected, including two Fellows and the Tonbridge Gardeners' Society, as also the Warrington and District Chrysanthemum Society were admitted to affiliation. General regret was expressed that Mr. B. Wynne had declined to be nominated for reelection as Chairman of the Committee, a post he has held for the past two years.

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

Rev. G. HENSLOW, of Drayton House, Ealing, writes: "Will any expert in Hyacinth growing kindly explain why the stalks often fail to grow, so that the flowers appear and expand close to the bulb?"

POINSETTIA PULCHERRIMA.—Hasany reader observed the production of seed-vessels by this plant. X.

Obituary.

JOSEPH CHAMBERLAIN.—Died on the 21th ult. For thirty-one years Foreman at Hyde Park; after an illness of a few days.

M. JORDAN.—We learn from the *Revue Horticole* of the death, at an advanced age, of M. JORDAN, the eminent botanist. He was not only a closet botanist, but cultivated the plants in which he was interested

and to each minor variation of a constant character he applied a specific name, so that he was a "splitter" *par excellence*. M. VIVIAN MOREL, now of Lyon was his head gardener.

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Days.	TEMPERATURE.				RAINFALL.	BRIGHT SUN.
	Above 42° for the Week.	Below 42° for the Week.	Day-deg.	Night-deg.		
6	3	0	42	35	84.6	25
11	1	1	43	44	97.5	21
2	1	4	35	35	42.3	30
3	1	8	32	36	20.3	32
4	2	12	29	42	30.3	27
5	2	18	11	31	18.1	27
6	1	4	29	50	72.4	20
7	1	8	21	38	32.2	27
8	4	24	1	28	15.5	24
9	4	13	21	55	50.1	26
10	3	20	1	37	21.1	26
* 4	4	0	4	5	16.1	36

More (+) or less (-) than Mean for the Week.

No. of Rainy Days since January 5, 1897.

Total Fall since Jan. 5, 1897.

Percentage of possible Duration for the Week.

Mean since Jan. 5, 1897.

The districts indicated by number in the first column are the following:—
 1, Scotland, N.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S.; 6, Principal Graining, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; *Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending February 15, is furnished from the Meteorological Office:—

"The weather continued dull and unsettled over the Kingdom as a whole, but the amounts of rain were comparatively slight, and less frequent than of late, except at the south-western stations.

"The temperature was rather above the mean in most districts, but a little below it over Scotland and in England, N.E." The highest of the maxima were registered on the 9th, when the thermometer rose to 56° in the 'Midland Counties,' and to between 50° and 54° in the other districts. The lowest of the minima, which were recorded on the 8th over England, the 12th in Scotland, and on irregular dates in Ireland, ranged from 16° in Scotland, N., and 19° in Scotland, E., and 20° in England, S.W. and Ireland, S., and to 37° in the Channel Islands.

"The rainfall was less than the mean in all districts, excepting England, S.W. and the Channel Islands," where there was a considerable excess. Over the north eastern parts of Great Britain the fall was very slight.

"The bright sunshine again shows a deficiency in most districts, but was in excess in the north and east of Scotland. The percentage of the possible duration ranged from 25 in Scotland, E., and 20 in England, N.E., to 5 in England, S. and N.W., to 5 in Ireland, S."

MARKETS.

COVENT GARDEN, FEBRUARY 15.

FRUIT.—AVERAGE WHOLESALE PRICES.		s. d. s. d.

POTATOS.

There are large stocks on hand; very few samples stand clear, and prices have again fallen for second class. Dunbar Maincrop, 8s. to 8s.; Dunbar Saxons, 7s. to 7s.; Lincoln Maincrop, 5s. to 7s.; do. Savons and Abundance, 4s. to 7s.; do. Giants, 5s. to 5s.; Blackheads, 3s. to 4s. John Bath, Wellington Street, Covent Garden.

SEEDS.

LONDON: February 17.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that there were but few buyers on to-day's seed market, and the business passing, owing, doubtless, to the still water-logged state of the land, was limited in extent; indeed, the present season promises to be a late one. Prices for Clovers and Rye-grass seeds are without material alteration. For Tares there is a good inquiry at full rates. A cultivator just returned from New Zealand reports the Clocksfoot crop much damaged by heavy rain. A speculative movement which has sprung up is advancing potatoes for Canada seed. There is no change in Hemp seed. Peas and Haricots sell more freely at the moderate rates current. Scarlet Runner Beans are now obtainable on very low terms.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qtr.) for the week ending February 13, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Outs	11	11	11	8	+3
Bulw	11	11	11	6	+5

FRUIT AND VEGETABLES.

LIVERPOOL: February 17.—Average of the prices current at market during the past week:—Fruit: Peas, 8d. per lb.; Apples, 1s. to 2s. per stone; Tomatoes, Guernsey, 8d. per lb.; do., Scotch, 10d. do.; Grapes, home, 2s. to 3s. do.; do., foreign, 8d. do. Vegetables: Turnips, white, 6d. doz. bunches; do., Swedes, 1s. to 1s. 4d. per cwt.; Savoys, 10d. to 1s. 3d. per dozen; Cabbages, 6d. to 8d. per dozen; late do., 10d. to 1s. do.; red do., 2s. 6d. to 3s. do.; Cauliflowers, English, 2s. to 2s. 9d. per dozen; Parsnips, 1s. to 1s. 6d. per cwt.; assorted Herbs, 1d. to 2d. per bunch; Leeks, 1s. 6d. to 4s. per dozen bunches; Mint, green, 6d. per bunch; Onions, Dutch, 3s. to 3s. 9d. per bag; do., Portugal, 1s. per stone; do., Globe, 7s. 6d. to 4s. per cwt.; Parsley, 3s. to 4s. per stone; Greens, 3d. to 4d. per bunch; Celery, table, 1s. to 3s. per bundle; do., common, 9d. to 1s. do.; Potatoes, best, 6d. per stone; Carrots, 3s. to 4s. 6d. per cwt.; Broccoli, 2s. to 3s. per dozen; Artichokes, 10s. to 12s. per cwt.; Cucumbers, 12s. to 15s. per dozen; Lettuces, round, 6d. to 9d. do.; do., French, 1s. to 1s. 3d. do.; Raddishes, 6d. per dozen bunches; Horseradish, 2s. to 2s. 6d. per bundle; Mushrooms, 1s. to 1s. 3d. per lb.; Rhubarb, 1s. 9d. to 2s. per stone; Beetroot, 10d. to 7d. per bunch; Cross, 3d. per basket; Brussels Sprouts, 2s. to 2s. 6d. per stone; Endive, 1s. 6d. to 2s. per dozen; Spinach, 3s. to 4s. per stone.

LIVERPOOL: February 17.—Average of prices at following markets:—St. John's, Potatoes, 8d. to 10d. per peck; Cucumbers, 1s. each; Grapes, English, 2s. to 3s. per lb.; foreign do., 6d. to 8d. do.; Parsley, English, 4s. to 5s. each; Mushrooms, 1s. 3d. per lb. Birkenhead—Potatoes, 6d. to 8d. per p. doz. Cucumbers, 8d. to 1s. each; Grapes, English, 3s. per lb.; foreign do., 6d. to 8d. do.; Pines, foreign, 2s. to 5s. each; Mushrooms, 1s. to 1s. 6d. per lb. North Hay—Potatoes, Imperators, 1s. 8d. to 1s. 10d.; Giants, 1s. 8d. to 1s. 10d.; Main Crop, 2s. 6d. to 2s. 6d.; Chappin, 1s. 8d. to 2s. 2s. Broccis, 1s. 10d. to 2s. 3d. per cwt.; Turnips, 10d. to 1s. per 12 bunches; Swedes, 1s. 3d. to 1s. 6d. per cwt.; Carrots, 3s. to 3s. 6d. do.; Onions, 4s. to 4s. 6d. do.; do., foreign, 7s. to 8s. 6d. do.; Parsley, 12 bunches, 10d.; Cauliflowers, 1s. 6d. to 2s. per dozen; Cabbages, 8d. to 1s. 6d. do.; Celery, 6d. to 1s. 4d. do.

APHIS ON BROAD-BEANS: D. B. S. The species is *Aphis papaveris*—the winged insect shining black, the wingless dull black. These insects suck the juices of the young tender stems, flower stalks, and lower sides of the leaves, causing red-brown patches on the latter. The insects void a sweet liquid, the so-called honeydew. This is the commonest species; a less common one is *Siphonophora visca*, which is grass or olive-green, [the winged insects] black with body of green and black in the hinderpart. A mixture of soft-soap, soot, water, and tobacco-juice, applied with a syringe, will clear them off. If they infest merely the tops of the stems, cut off the latter and burn them.

BACTERIA AS PLANT FOOD: Ctesar. If the experiments with nitrogen are meant, we believe that the substance has proved of no use in field culture of crops.

BOOKS: C. A. Britton, Vines and Vine Culture (171, Fleet Street); Ward, My Gardener (Eyre & Spottiswoode, East Harding Street, E.C.).

DENDROBIS: X. Y. Z. We knew nothing of *Dendrobium fimbriatum aureum*. The typical *D. fimbriatum* has wholly yellow flowers; and *D. fimbriatum oculatum* has similar flowers, but with a dark chocolate blotch at the base of the lip. Probably if you rested your plants in the latter part of the summer in an airy vinery or greenhouse they would give more spikes of flowers.

EARLY VINERY STARTED DECEMBER 1: E. H. Not detrimental to the Vines if the process of forcing is very gradual, as in all cases it should be. Should the Vines have been forced early in previous years, they will start in growth quicker than would be the case with Vines not so treated. Of course, early forcing is not without its ill-effects on Vines in course of time.

EGGINS FOR A BED OF LOBELIA CARDINALIS: A. P. As a hardy annual sowing you might use a broad hand of *Agave reptans*, a broad-leaved Begonia with crimson flowers, or some strong-growing tricolor *Pelargonium* with a red zone in the leaf; or, if the bed be a large one, and made on the lawn with a wide expanse of turf around, Brazilian Beet would have a good effect. If you decide on an edging that will contrast with the reddish foliage of the *Lobelia*, you might employ *Centaurea ragusina*,

Cineraria maritima, *Chamaeopa diantha*, silvery variegated *Pelargoniums*, as *Bijou*, *Flower of the Day*, &c. A green-leaved *Canna* of low growth, such as *C. Eleanora*, or a drooping broad-leaved plant, as *Panicum salsitium*, would look well if the bed is one of large size. *Lobelia* beds should always be made convex in form, as by that means a greater number of the plants are seen at a glance, and the space left for the edging plants ample, otherwise there will be the appearance of the latter crowding the plants that provide the chief display.

EDINBURGH ROYAL BOTANIC GARDENS: Rural. If you state your wishes to Professor J. B. Baifour, the director of the establishment, you will doubtless be furnished with the desired information.

FUMIGATING A VINERY WHISTLE FRUIT AND LEAVES ARE STILL ON THE VINE: Rural. To do so would be imprudent, as the fumes might injure the Grapes, and certainly would impart an unpleasant flavour to them. It is quite safe to use XI. All Vapour, the odour being not perceptible after the lapse of a few days.

GROWERS IN THE CHANNEL ISLANDS: C. S. N. The Fruit Growers' Year Book for the present year, price 1s., will give the information sought. It is published at the Cable office, 30, Fleet Street, E.C.

GRUBS GNAWING VINE ROOTS: J. Herd. The grubs seen are those probably of the Vine-weevil, *Otiorhynchus sulcatus*, which you must get rid of, or they will work great injury to your Vines, both as grubs gnawing the roots, and perfect beetles eating the buds, &c. For a method by which to catch the latter, see the *Gardeners' Chronicle* for February 15, in answer to correspondent, "W. M.H." The weevil grubs are much more difficult to exterminate however, and as they live nearly near the surface, and under clods and stones, the soil, &c., should be turned over with a hand-fork, going carefully all over the area, picking up the grubs and destroying them.

INSECTS: W. A. G. A large parasitic Ichneumon Fly that has been the means of destroying some larger and probably injurious caterpillars.

MANURES FOR FRUIT TREES, &c.: H. R. Mineral phosphates of lime, or bones treated with sulphuric acid, i.e., superphosphate of lime, and such as contain much potash. These manures suit stone fruits. Apples, Pears, and bush fruits may be afforded artificial manure, rich in nitrogen applied at the rate of 6 to 10 lb. per tree a year, in two or more dressings. The same would suit the Strawberry, but adding a larger amount of potash, using the manure as a top-dressing in showery weather in spring and early summer.

MEDICINAL PLANTS, &c.: J. C. L. *Vanilla aromatica* would not succeed in your greenhouse, the plant being a native of tropical South America, and requiring the temperature of a hothouse. Indeed, there are but very few medicinal plants which could be successfully grown in a greenhouse; but if you could heat the house, say in winter from 58°–70°, and in summer from 63° to 85°, there are many species which could be cultivated, of which we may indicate *Cephaelis Ipecacuanha*, *Cinchona lanceolata*, *C. nobilis*, *Maranta arundinacea*, *Piper Betel*, *P. Culeba*, *Quassia amara*, *Smilax Sarsaparilla*, *Myroxylon balsamiferum*, *Amomum cardamomum*, *Cinnamomum verum*, &c. Besides these there are such plants as yild substances used in the arts, or as food, as *Indiarubber*, *Sugar-cane*, *Cotton*, *Catappa*, *perilla*, *Ginger*, *C. or Tea*, *Coffee*, *Cocoa*, *Kola*, *Cabbage-Palm*, and many others. A visit to the Economic-house at Kew will give you many more examples.

METHODS OF PROPAGATION: A. P. We are pleased to know that the articles have been found of use, but we are unable to say if the writer of them intends to publish them at some future time in book form. We hope that he does, and should raise no objection.

NAME OF FRUIT: Scott, Northern Greening.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to so good as to consult the following number—A Constant Reader. Very brightly coloured variety of *Leila* anemones, and *Cattleya Trianae* rosea.—*C. L.* 1, *Odontoglossum Andersonianum*; 2, an immature or imperfect flower of *Odontoglossum crispum*.—*Fic. Croft.* Newly-imported plants of *Deudrobium Wardianum* frequently produce flowers of large size, similar to these sent, and afterwards the blooms come of the

usual size. Will you let us see a flower from the same plant next year!—*R. N. H.* A very pretty variety of *Cattleya Percivaliana*. The labellum is larger than usual, and the broad lilac margin is an effective feature.—*J. F.* The brilliantly-coloured Lichen is *Cladonia coccinea*, common in heathy places.—*A. S. K.* 1 specimen insufficient; 2, *Haworthia margaritacea*; 3, *Sentia* *Komari* *aureo-maculata* (*Farfugium grande*); 4, *Euphorbia splendens*; 5, specimen insufficient; 6, *Eucalyptus glauca*; 7, *Fuchsia procumbens*; 8, probably *Campanula fragilis*; seed when in flower; 9, *Myrsiphyllum meledoides*.

SEEDING CINERARIAS: Constant Reader. If you are desirous of obtaining certain colours, forms, &c., the plants to be operated upon must be placed in a house a good distance away from the rest of the plants, covering them securely with hexagon netting so as to exclude the bees. Then you must proceed to cut off every bloom that was expanded at the time of removal, so as to have no chance crosses, but only those you desire, which may be attained by cross-fertilising by hand, or allowing the wind to carry the pollen from one plant to another. The first is the better method, but the chief condition is isolation from other plants, pollen being brought to it from one or more plants; and when this is done the portions of the corymb operated upon by different pollen, should be indicated with small parchment tickets. Having obtained by this means flowers of excellent form and colouring, it will suffice for some years to keep the batches of different colours apart in pits or houses, distant from each other, and permit self-fertilisation to take place. The results will be good for a time, but as long there will be re-versions, more or less marked, to the earlier forms, and crossing by hand on outside plants will have again to be had recourse to.

THE BEST VARIETATED-LEAVED PLANT FOR FILLING A HANGING BASKET: F. B. The best is a matter of taste. For a hothouse, there are *Cissus discolor*, *Cyrtodeira glabra*, *Pothos argyrea*. For a greenhouse or verandah there are *Siphonophora europaea* variegata, *Sedum Sieboldi*, *Saxifraga sarmentosa*, *Fuchsia Sunray*, *Pelargonium Manglesii*, *Leucophyta Browni*, very slender plant, with grey stems and foliage; or *Mesembryanthemum cordifolium* variegatum.

VINERIES: Vinciplanting. The new house is not built according to modern ideas, but good Grapes can doubtless be grown in it. The space in the front need not be wasted, Grapes growing just as well on that part of the stem which is vertical as on the oblique parts, that is if you do not crowd the Vines with plants in pots. The best Grapes are grown on Vines planted in inside borders, with access to an outside one; but such borders require more attention, and are expensive in keeping them in a healthy condition. The "winter rains" do good not harm to the Vines, and it is only when early forcing is carried on that the border needs warmth, and protection from the elements. A border 9 feet wide would support Vines for five or six years, and would then require to be renewed or made wider, or both. If you have a border outside and another inside, they should be on one level for some distance, say 1½ yards from the front of the vinery, being continued with a moderate slope to the margin. Could you not lift your old Vines that are planted in the outside border in September, make a new border inside and out, and build a new front wall resting on piers? You would then have the opportunity to make the new borders of one level. If the Vines are planted inside there will be no need of holes in the wall to put the Vine stems through, and the roots will extend to the outside by means of the wide openings beneath the foot of the wall. The Vine stems can be protected from the heat given off by hot-water pipes by enclosing them (the stems) in wooden pipes or pieces of cork, and the roots just below the pipes by a thick mulch or a line of stout planks.

THE

Gardeners' Chronicle.

SATURDAY, FEBRUARY 27, 1897.

VARIATION AND ENVIRONMENT.

CAREFULLY studying the various articles which have recently appeared in this connection, and especially that of the Rev. G. Henslow in your issue of January 30, I am forced to the conclusion that scientific botanists do not take into sufficient account the capacity of plants to sport, and sport into extreme types, under such normal conditions of environment as preclude the idea that a change in these has constituted the stimulus to the variation observed. Mr. Henslow remarks, "That no true variety will arise if the environment be constant is a belief based on a large amount of observation, but that new varieties only arise in consequence of 'changed conditions of life,' as Darwin and Wallace call them, is accepted, I suppose, by all evolutionists in Europe. Indeed, these essays, *The Survival of the Unfit*, J. H. Bailey, New York, abundantly corroborate this belief." Further on he quotes Mr. Bailey thus: "I believe that the greater part of the present differences in organisms are the result, directly and indirectly, of external stimuli," and accepts this conclusion as correct, deducing from it that "mutability depends upon environment." Finally, Mr. Bailey's three suggested causes of variation are quoted, viz.: "(1), External stimuli; (2), Internal acquired energy (as seen in sports, primarily due to cultivation); and (3), Sexual intermixing."

Now all these quotations and axioms, except (3), as last quoted, which is outside the present mission, point in one direction, viz., that without a change in the environment, plants remain constant, and with this point I propose to deal in connection with Ferns, that particular family of plants which I have now assiduously studied for many years in its variated aspects, both as a selective cultivator, and what is particularly to the point, as a searcher for new forms in the wild state.

With regard to Ferns, our British species especially, there is, I imagine, no class of plants existing in the world which has been the object of so much research in their wild and perfectly uncultivated state, and certainly none which has yielded such a rich harvest of wild departures from the normal types under natural conditions of growth. The distinct and constant varieties thus found number certainly many hundreds. This being so, I am, I think, perfectly justified in regarding the evidence afforded by the results as peculiarly to the point, and as the bulk of it is established beyond all doubt by records contemporaneous with the "finds," and made by more reliable authorities, it merits serious consideration by all evolutionists. The reason why it has not, to my mind, received this consideration so far is, that Fern-hunting has been peculiarly an amateur's hobby, demanding a great expenditure of time

and patience, and stimulated by a faith which can only be engendered by a certain amount of good fortune at the outset. Hence the enthusiasts, all told, are very few in number, and the truly scientific botanist is not found among their ranks, because his time is too much absorbed in systematic study and research in other and better-defined directions to permit of it. The immediate result of this is a tendency on the part of the scientist to relegate all the abnormal forms to the "garden" varieties, and to ignore the very important fact that the large majority of forms owe nothing whatever to the stimulus of cultivation, but originated under precisely the same conditions of environment as the millions of normal Ferns among which they were found.

All the typical variations, and among them some very extreme forms, were thus found, and although it is quite true that under selective culture their distinctive characters have in some cases become more developed in their progeny, in a large number of instances the original finds have not only survived—for Ferns seem to have no definite limit of life—but they have been propagated by division as well as by spores; so that every good collection affords plenty of original material for studying what variation can arise, independently, as I maintain, of any of the three causes suggested by Mr. Bailey. For instance (and here be it observed, I have some of my own "finds" in mind, as well as those cited), what "external stimuli" can we imagine capable of transforming the normal frond of *Athyrium filix-femina* into that remarkable pereruciate cristate form known as A. f.-f. Victoriae, a solitary plant of which was found growing with the common form in abundance around it, under purely natural conditions, "by the side of a by-way on the margin of a wood?" How can we imagine an adequate stimulus so extremely local in effect that no second find of the type has turned up among all the Ferns of the world? "Internal acquired energy" there must, of course, have been in the spore or the prothallus; but Mr. Bailey confines this cause to "sports, primarily due to cultivation," with which category this plant cannot possibly be classed. This extreme case is a type of many. The hunter descends into a glen untouched by the hand of man, and seldom by his foot. Ferns of various species line the rocky banks and peep from every crevice, hundreds and thousands; all may be without a trace of variation, and suddenly in one of the myriad chinks in the self-same rock-formation or bank of drifted alluvial in which the rest are rooted, and mingling its roots and fronds with theirs, he finds one, and one only, of an altogether different type. Removed and put under culture, changing its environment thus very completely, it not only retains its peculiar form from generation to generation of men, but even its progeny may be true to its type, the great change in environment producing no appreciable subsequent effect whatever.

Again, I ask where is the external stimulus in such a case as this? and add, why has the subsequent stimulus of protective culture no apparent effect whatever upon a variation already presumed to be caused by a difference in environment, which is quite inappreciable to investigation? Surely, were difference of environment the exciting cause in those wide variations, we should expect to find traces of similar effect in the other plants with which it was actually mingled in the vicinity; but evidence of this sort is rare, or rather, non-

existent, since although it occasionally happens that several independent plants are found near together, they are generally so identical in type as to be ostensibly seedlings derived from the original sport, which may or may not be discriminated from the rest by its larger size. Where, too, in all these cases, can we find evidence of the changed conditions of life, to revert to Darwin's and Wallace's phrase already quoted, as essential to the appearance of new variations? In the case of roadside finds, which are not infrequent, the conveyance to them by wind of a certain amount of manural dust, may be urged as possible, and I yield to the argument that here, at any rate, purely natural conditions are vitiated, while doubting much if the varieties even here are in the least induced thereby; but in glens, mountain-sides, and rocky Fern-habitats in unfrequented spots, there is nothing that I can conceive constituting such a change of conditions of life as would induce an altogether different structural plan, and one, moreover, which in some forms of variation is actually adverse to its continued existence. An *Athyrium*, for instance, I found in a wood in Ireland, was so heavily crested, moreover so brittle in structure, that it was dwarfed and battered to pieces by the little wind it met with there; but under glass it became a fair-sized plant. Another point is, that these varieties start as such from the prothallus, and their peculiarities do not originate as the plant grows up. Hence, we must antedate the sport as prior to the existence of the Fern itself. The parent Fern of an initial sport must be externally normal, and it is this which must be so affected by "changed conditions of life," that its spores become modified; yet, as I have said, the general environment is at once normal, and has evidently undergone no essential change of climate, temperature, soil, aspect, or anything else, beyond the ordinary vicissitudes of weather, it and the plants in it have been subjected to for ages.

It seems to me, therefore, in view of these facts, which can be easily demonstrated, the belief "that no true variety will arise if the environment be constant," cannot possibly be upheld, since many true Fern varieties have undoubtedly arisen where the environment has been unchanged. "External stimuli" are also exceedingly difficult to bring in as factors, as, under the circumstances described, we can hardly conceive these to be concentrated upon one normal plant in such a way as to cause it to modify its spores—or a single spore, it may be—so profoundly, as to yield so different an offspring, endowed moreover with such constancy of reproduction of its own particular type, that subsequent entire change of environment fails to alter it. Internal-acquired energy, in these cases, cannot be derived from external stimulus, nor seemingly from any special stimulus of environment; while "sexual intermixing" is out of the question where the crossing can only be between normals of same species. All these causes failing, therefore, to satisfy my mind, I am driven to the conclusion that, so far as the causes of initial variation are concerned, we are absolutely in the dark at present. Once a species sports, we can easily conceive that the subsequent variation in the progeny to which our horticulturists, agriculturists, cattle-breeders, &c., owe so much results from the varied *modus vivendi* arrived at by the conflicting elements of being present in the conjoined primordial germs; but the cause of the first departure

is a profound mystery, as is the point of its commencement. In the Fern, it may be in the spore, it may be in a modified atherozoid or archeogonial cell, or it may even be in some subtle local modification of the parental Fern, which consequently produced the modified spore; but in any case, for the time being, the origin of life itself and that of its subsequent initial variation must be classed with first causes, and therefore with the unknown, if not with the unknowable. At any rate, it is well, as research proceeds, to guard against the accepting as "beliefs" of theories which cannot be substantiated, since the history of science is only too rich in stumbling-blocks of this description. Another moral which I deduce from the foregoing is, that the study of domestic plants alone is not sufficient; what is needed is a more extended study of plants in the wild state. This, I am certain, would lead to considerable modifications of the ideas at present held of the greater variability of plants under culture. Most of these owe their variability not so much to the culture, as to the fact that they are the progeny of "sports," and hence more apt to vary again for reasons above cited; but by my own opinion, based on experience in my particular line is, that original "breaks" occur just as frequently under natural conditions as under culture, though the examples being isolated and scattered about among the myriads of normal plants, are infinitely more liable to escape observation than where the plants from seed to fruition are under the trained eye of the grower over in the *qui vive* for novelties. *Chas. T. Dreury, F.L.S.*

NEW OR NOTEWORTHY PLANTS.

CYPRIPEDIUM TRIUMPHANS = SALLIERI HYEANUM × CENANTHUM SUPERBUM.

ONE more novelty of foremost rank was seen in flower in the collection of Thomas Statter, Esq., Stand Hall, Lancashire. The dorsal sepal is of rhomboid form across the centre, and lessening slightly towards the base, and less so towards the apex. The blood of the fusion is very marked, and enhances the quality of the limb which is coloured, in detail, too, back as well as front. The petals and pouch resemble the pollen parent in form and colour. There were two flowers on the plant, one of which was sent to Mr. Macfarlane for figuring in colours, and the other remained on the plant.

The rhomboidal dorsal sepal is of the size of that of the largest *C. Sallieri*, and the two-thirds of its surface has a yellowish shaded green ground, upon which chocolate or rather magenta coloured spots, the size of Sweet Pea seed, are crowded together almost to overlapping, although keeping their orbicular shape. These spots get smaller and brighter to wards the apex. The colours are decided, and give character to the flower. The under portion of the back differs from the front in having emerald green lines radiating from the base towards the apex, stopping short of the white ground; and the ground colour is flushed with pink, and narrowly margined with white. The inferior sepal is in form ovate acuminate, two-thirds of the size of the dorsal sepal, has a greenish ground colour adorned with a white margin, the apex being particularly noticeable. The petals, as in *C. cenanthum superbum*, are of a vinous red colour, with a yellow margin, which is very striking. The pouch is identical in colour with the petals, and excellently formed. The staminate is very large, more cordate than the staminate of either parent, and has an elongated tubular shaft attaching it to the basal limb, from whence it springs. The colour of the cordate extremity is of a fine yellow shade. It has the appearance of being of good constitution, and bears a longish peduncle, always a desirable feature. *J. Anderson.*

ORCHID NOTES AND GLEANINGS.

DENDROBIUM KENNETH (BENSONIÆ & MACCARTHIE ?). (See Fig. 37, p. 135.)

DENDROBIUM MacCarthie, a plant generally considered difficult to grow, has flowers of such beauty, which differ so greatly from those of other species, that crosses obtained from it are extremely desirable. So thought Norman C. Cookson, Esq., of Oskwood, Wylam, near Newcastle, when he and Mr. Wm. Murray, his gardener, crossed *D. MacCarthie* with pollen of *D. Bensonie* in 1889. The seeds ripened, and were sown in July, 1890, and the plants made such rapid progress that he was enabled to show it for the first time in flower on March 10, 1896, a fact duly recorded in the *Gardeners' Chronicle*, the plant having the Award of Merit of the Royal Horticultural Society.

Mr. Cookson again exhibited a plant at the meeting on February 9 last. By a mistake when it was first exhibited, *D. Bensonie* was placed as the seed-bearer, but Mr. Cookson informs us that he has never been able to get a pod of seed on that species. These who are not used to the vagaries of colour in crosses and hybrids would expect to see more of the rose-colour and purple of *D. MacCarthie* blended with the cream-white of *D. Bensonie*, but these are two tints which when apparent in the parents often quite disappear in the offspring. The form of *D. MacCarthie* in the cross is strikingly shown in the long segments, and more especially in the elongated form of the lip. The colour of the flowers is cream-white, with a downy purple veining on the disc.

DENDROBIUM WARDIANUM CANDIDUM.

A good example of what is often named *D. Wardianum album* is sent by Mr. Wm. Bolton, Wilderspool, Warrington. The flower is of good size, pure white, with a yellow base to the lip, on which are two small but clearly defined red-brown blotches. *Apropos* of these white varieties of *D. Wardianum*, it may be mentioned that they not only vary in size from one year to another, but they are more especially liable to vary in the size and depth of colour of the red-brown spots on the lip. A few years ago Chas. Winn, Esq., The Uplands, Selly Hill, Birmingham, noted that a white *D. Wardianum*, whose flower had been remarkable in that the brown marks on the lip had been previously almost entirely suppressed, on flowering again had them as well defined as in some ordinary *A. Wardianum*.

DENDROBIUM WARDIANUM VAR.

The beautiful *Dendrobium Wardianum* is at this season one of the most beautiful of Orchids, and much variety is displayed in examples received from different correspondents. The large-t and most richly-coloured comes from Mr. W. H. Young, Orchid-grower at Claro Lawn, East Sheen. This flower is excellent in every point, and especially in the pure whiteness of the petals, and deep rich claret-purple tints to the sepals, petals, and lip. The sepals are likewise tinged with purple at the back, which is visible from the front through the substance of the flower. The petals are heavily tipped with rich claret-purple. The labellum is of a bright orange hue, and possesses the usual red-brown blotches at the base; the apex is pure white, except the tips, which are claret-red. *J. O'B.*

RENANTHERA COCCINEA.

This quaint and interesting Orchid is now in bloom with us. The plant is bearing sixty blooms on a five-branched raceme, which are of a bright brick-red colour. It is the more interesting because of its peculiar mode of growth. Our plant is climbing a pole about 9 feet high—à la mode de *Spéed de Chatsworth*—and is growing in a span-roofed structure, 40 feet by 20 feet by 11 feet, and this where the temperature during the continuous winter of 1894-5 frequently fell to 35° Fahr., the house being fully exposed to the east. Up to two years ago I grew the plant in a small stove, where it was exposed to the sunlight as much as possible; but not being satisfied

with the progress it made, it was placed at the cooler part of an intermediate-house, which was in use for exhibiting all kinds of hard and soft-wooded plants, including Orchids. I find that to be well wetted with the syringe three times a day in summer and once in winter accords with its requirements. The progress made during the past two years by the plant in the intermediate-house has been rapid, and the foliage is lustrous and healthy looking. Doubtless many plants of *Renanthera* are grown in too much heat, and if those gardeners who have more than one plant would try one or two in a temperature of 50° to 60° in winter, and 70° in summer, they would be well satisfied with the results. By the way, have any of our Orchid hybridists taken *Renantheras* and *Vandas* in hand? In case any of them require pollen masses to experiment with, I should be pleased to give it. *W. J. Grace, Bickton, Fordlingbridge.*

THE FLOWER INDUSTRIES OF SOUTHERN FRANCE AND PARIS.

FROM December till May is the season for the flower industries. It is only within the last fifteen years that the commercial culture of flowers in France has attained its present large proportions. The area now devoted to flower-farms, where entire fields, not beds, are cropped with the most lovely and odiferous flowers, lies in the area twenty by ten miles in extent which takes in Cannes, Nice, and Grasse. The climate as well as the soil are especially suitable to the enterprise in question. Sub-divisions of the area have also their peculiar floral out-put, Cannes, Nice, and Antibes are reputed for their famous Roses; Grasse for its Jonquils, Violets, Tuberoses, Jasmine, Mignonette; Hyeres and Fréjus, for Violets; the suburbs of Cannes, for Pinks. Bulbous plants succeed everywhere.

In the matter of profit, the districts of Antibes and Cannes rank first; excellent outputs are also secured round the Golfe de Juan and Beaulieu. The total area actually cropped with flowers is nearly 1800 acres, of which the commune of Nice represents 500, and Cannes, Antibes, Mentone, and Grasse each 250 acres. The villa residences commence to encroach on the flower lands, but the house proprietors themselves grow flowers, and that, with letting their villas, helps to make up the means of living. The very large growers of flowers resemble, it may be said, large farmers; they sell their produce to the laboratories or to contractors, or they enter into partnership with intelligent labourers, and divide profits. This is the *netayer*, or partner, system applied to floriculture. In the winter season the culture is confined to the raising of cut and ornamental flowers. In summer the aim is to cultivate for the laboratories, that is, distillation for perfumery, to prepare essences, pomades, and scented "waters;" it is also the season for gathering-in seeds. It is a popular error to suppose that no skill or outlay is required to produce the supplies of flowers for northern latitudes between Christmas and May. Flower culture exacts capital and increasing care. Doubtless many conclude that the flowers grow naturally in the open air—this is an error; some do, but the most delicate and the most beautiful species are raised under glass. In the regions of Nice, Grasse, and Mentone, there are 200 acres of land covered over with glass frames, each frame costing at least 7s., so that much capital is sunk in the industry. Other flowers are raised under canvas tents, and many are protected by matting. Roses and Pinks are grown under glass; white white Lilac, Lily of the Valley, and also Pinks are forced into bloom in the space of eighteen days. The Lilac is white, because grown in darkness, but when exposed to the sun, it rapidly assumes its tints, and no fewer than 200 shades of Lilac have been recorded—a collection the late M. Chevreul never could delineate. It is in the bloom and colour-producing efficacy of the sun that much of the secret of flower farming resides. Violets are generally grown beneath the shade of Orange trees, or under the shadow of walls. The Russian variety is classed first, then the Queen Victoria, which is of a deeper hue.

Flower-culture could never have succeeded were it not for the railway companies facilitating the industry. They guaranteed the quickest trains from the South to the North of France, accepting the flowers packed in special oster-baskets, and limited to parcel-post weights, never exceeding 11 lb. It is thus that Nice, and other places, supply London, Berlin, Stockholm, &c. None goes to St. Petersburg: the parcels, even for the Imperial family, are too severely handled while passing through the Customs. Germany is the best customer of France for flowers. The prices of flowers depend upon the weather and fashion. Formerly, Berlin gave the top prices, now all are on a level; while the cultivators have their own daily latest market quotations published as if it were corn, pork, or coal. At Cannes, Roses range from 2*l.* to 7*s.* per dozen; Pinks, 1*d.* to 4*s.*; Orchids, 1*s.* 6*d.*

the essence. Nice and Grasse work up yearly 800 tons of fat, and 500 of oil, in the preparation of perfumery. It takes 25 tons of Rose petals to prepare 2½ lb. of essence of roses, the latter representing £100. In 1892, the railway station at Cannes alone forwarded 900 tons of flowers, valued at £160,000. The profits of flower farming fluctuate between 8 and 18 per cent.

France alone consumes the moiety of the total of her flower out-put. Paris is the great consumer; the capital needs perfumes and flowers for its *fêtes*, weddings, and funeral ceremonies. It wishes flowers upon mantel-pieces above a blazing fire—for bouquets in the eyes of French people mean gaiety. A bunch of Parma Violets can gild into a muff, can decorate a button-hole, or ornament a corsage.

The wholesale market of Paris, with which the

In addition to the special "local" flower markets of Paris, there are 230 *fleuristes* —there were only 45 in 1870—or flower shops, that have magnificent contents along the leading boulevards and main thoroughfares. Their windows are often marvellous displays of floral wealth, united to art. The contents of each window constitute an object-lesson in the harmony of colours, in the arrangement of shades and of volume, of flowering plants (the taste is sometimes questionable, witness the large ribbon bows and satin streamers intermingled). What wreaths, what bouquets, what painting of the Lily! All is the work of the special lady shop-assistant, known as the *coloriste*; she receives £12 per month for merely dressing the window, and inventing combinations for bouquets. The *fleuristes* in Paris are wealthy, like their customers, who command bouquets and plants varying from £4 to £20. Many of the *fleuristes* have their own greenhouses in the suburbs, and take by contract what is most beautiful for sale by private growers. They possess every flower "out" of season, of the very newest variety, with the freshest of bloom, and displaying the brightest colours.
Edward Conner.

C R A T E G U S.

(Continued from p. 131.)

C. DOUGLASSII.—One of the largest-growing of the genus, attaining a height of more than 50 feet. It is a native of Western North America, and was discovered by David Douglas in the valley of the Colorado River, and introduced in 1827. The leaves are obovate, elliptical, or cuculate, glabrous, and of a bright glossy-green, averaging 2½ to 3 inches in length and width, the upper two-thirds being serrated. The wood is armed with short, stout spines three-quarters of an inch long. The abundant white flowers are produced in broad cymes during May, each flower three-quarters of an inch across. Its small fruit, which ripens in August, is black and shining, and falls soon after ripening. Sargent says that the tree attains its greatest size in the valleys of Western Oregon and North California, growing most freely on the margins of streams, where it often forms impenetrable thickets. At Kew it is the largest of the *Thorus*.

C. flava.—A small tree of spreading habit, with darkly-coloured wood, well furnished with spines, 1 to 1½ inch long. The leaves are broadly ovate or obovate, as long as the spines, crenate, slightly lobed towards the apex, and slightly pubescent on the prominent veins. The corolla is ½-inch across, white, and the lobes of the calyx are very markedly glandular. The fruit is pear-shaped, ¾-inch long, and ripens late; its colour is greenish-yellow. It is not one of the most desirable *Thorus*, neither flowering nor fruiting with much freedom in this country. A native of the United States.

Var. elliptica (Sargent) is smaller and more shrubby than the type, and has thicker, broader leaves. It differs also in the fruit, which is small, and sometimes red, instead of yellow.

C. mollis.—There are few *Thorus* from either the Old or the New World which are better worth a place in the garden than this. It is one of the largest-flowered of the species, and its fruits are also of good size, and finely coloured. Its nearest ally is *C. coccinea*, and judging by the numerous forms in cultivation at Kew, it has probably hybridised with that species. It may, however, be generally distinguished by its larger and more pubescent leaves. In some cases the pubescence is so abundant that they are quite soft to the touch. The flowers are produced in large flat corymbs, and are fully 1 inch across; they are white, with a dark red ring in the centre. The fruits are mostly spherical, and about three-quarters of an inch in diameter, and of a deeper but not so bright a red as those of *C. coccinea*. Unfortunately, they fall early, and the trees are here of them by the end of September. *C. mollis* is from the United States, and is a tree of vigorous growth reaching 20 to 30 feet in height.

FIG. 37.—DENDROBIUM "KENNETH;" FLOWERS CREAMY WHITE; LIP PURPLE AT THE BASE.
(SEE P. 134.)

to 3*s.*; Narcissus that sell at one time at 1*d.* each, can at other times be had at the same price per dozen. Occasionally, taste runs in favour of white, red, or yellow colours. During the General Boulanger craze in France, and especially Paris, red Carnations obtained fancy prices, because the favourite flower of the then "hero of the day;" of late, these flowers do not sell at all.

Flowers for transport are generally cut before sunrise; the best only are chosen, and are packed with cotton, as in the case of Camellias, Roses, and such Orchids as do not stand the journey, or with tissue-paper, or even both. Accacia or Mimosa generally lines the baskets.

Flowers as a rule, are not distilled at Grasse, &c.; but the leaves, bark, seeds, roots, &c., of odoriferous plants are. The perfume in the other cases is secured by pressing the petals between layers of suet or lard; when the perfume has been absorbed, the grease is dissolved in alcohol, which in turn absorbs

writer only deals, is held in the central cross-alley of the Halles Centrales. In summer—April to September—the hours are 3 to 8 A.M.; in winter, 4 to 9. The right-hand side of the alley is reserved for the flowers from Southern France, as delivered by the railway vans; the left side is allocated to the floriculturists of Paris and its suburbs, who have forcing-pits and greenhouses of their own. There are about thirty-two licensed retail sellers, who pay 4*d.* for their stand of as many hours. There are two sworn auctioneers, who give security each for £100; their fee is 5 per cent. The thousands of small baskets from Nice, &c., of 4 to 11 lb. weight, are sold by the dozen; if possible, the same kind of flowers are disposed of simultaneously. Then there is in the distance a regiment of hawkers, who come to buy from the auction salesmen; they have a huckster, which they hire for 6*d.* a day, paying 2*d.* more for the liberty to trundle along the streets; these are the subaltern distributors of the floral harvest.

C. punctata.—A well-marked and handsome Thorn, with obovate leaves, which can always be recognised by the prominent parallel veins running from the midrib. The blade extends down each side of the petiole almost to the base, the upper surface being dark green and glabrous, the lower one paler green and pubescent; the leaves are 2 to 4 inches long, and irregularly toothed, except at the base. The wood is grey, and sparsely set with straight, stout spines, $\frac{1}{4}$ inch long. The fruit is almost globular, about 1 inch in diameter, and dark red in the typical form. Var. *xanthocarpa* (or *aurea*) has bright yellow fruits; var. *striata* has them red with yellowish streaks near the base; and in var. *brevispina* they are of a dark dull red. In all the varieties the fruits are speckled with small, pale-coloured dots. The flowers appear in May in large flat corymbs. This is a small tree, 15 to 20 feet high, in this country forming a low spreading head. It was introduced from North America in 1746. The species bears some resemblance in its foliage to *C. tomentosa*, and has by some authors been made a variety of it; but the smaller, more oval, and always erect fruits of *C. tomentosa* (not to mention other characters) make it abundantly distinct.

C. spatulata.—At Kew this is a small, flat-headed tree a few feet high, with light grey, thin branches, but in the United States it gets to be 18 feet or more high. The leaves are spatulate, firm and glossy, $\frac{1}{2}$ inch long, the blade narrowing at the base to a narrow strip at each side of the petiole; they are sometimes deeply three-lobed, or are undivided, with merely crenate margins. During some seasons the foliage remains on the tree, and keeps green up to the new year. The flowers are white, half an inch across, and appear in May. The haws are perhaps the smallest of any species in cultivation, being about one-eighth of an inch across; they ripen in October, and are then bright scarlet. This interesting and distinct Thorn is a native of the Southern United States, and was originally discovered by Michaux in South Carolina. Lindley figured it in the *Botanical Register*, t. 1846, as *C. microcarpa*, an appropriate name, but of later creation than the one here used.

C. tomentosa.—One of the most distinct of the North American Crataegus, and although bearing some resemblance to *C. punctata*, is easily distinguished from it by its very different fruits. It has ovate leaves 3 to 4 inches long, which are irregularly toothed except towards the base, dark glossy green and almost glabrous above, but covered beneath with a fine tomentum. The white flowers are $\frac{1}{2}$ to $\frac{3}{4}$ inch across, and appear on pubescent corymbs later in the season than most of the Thorns. It is not abundantly armed with spines; the few it possesses are 1 to $\frac{1}{2}$ inch long, and of a light grey colour like the branches. The fruits of this species always stand erect, and are of the same shape as the haws of *C. Oxycantha*, but larger; they are of a yellowish colour when ripe. The calyx-lobes adhering to the apex of the fruit are linear and toothed. This is a tree 10 to 15 feet high, and was introduced from the Eastern United States by Lee and Kennedy, of the Hammersmith Nursery, in 1765.

C. uniflora.—This is probably the dwarfest of all the Crataegus, being generally a bush 2 feet to 3 feet high. It is said, in rare instances, to become a bushy tree 10 to 12 feet high. It has slender needle-like spines about 1 inch long. The leaves are spatulate, and from $\frac{1}{2}$ to 2 inches long, with crenate margins; they are glossy dark green above, and pubescent on both surfaces, but especially so beneath. The creamy-white flowers are solitary or occasionally in pairs, and $\frac{3}{4}$ to $\frac{1}{2}$ inch across. They are followed by pear-shaped fruits 1 to $\frac{3}{4}$ inch long, greenish-yellow, with large calyx-lobes still adhering at the apex, which are nearly $\frac{1}{2}$ inch long, strap-shaped, pointed and toothed. This species is one of the late-flowering group, and is often pretty in the early weeks of June. Its dwarf habit, solitary flowers, and large sepals, make it one of the most distinct. It was introduced from the United States by Bishop Compton in 1713.

C. coccinea (syn. *C. arborescens*).—A small tree,

reaching in the United States a height of 20 feet or more. The leaves are mostly obovate, bright green above, glabrous on both surfaces, and minutely crenate, occasionally slightly lobed, and from $\frac{1}{2}$ to 3 inches long. The wood is, as a rule, devoid of spines, but what few there are, are about 1 inch long, sharply pointed, and pale-coloured. The flowers are white, three-quarters of an inch across, and produced in May; whilst the fruit is bright scarlet or orange-coloured, and about three-eighths of an inch in diameter. This species does not appear to be of great value in Britain, neither flowering nor fruiting in great abundance. *W. J. Bean.*

FLORISTS' FLOWERS.

GARDEN PINKS.

OUR garden Pinks can be appropriately divided into a few types. There is the section of white Pinks represented by Mrs. Sinkins, Her Majesty, Snowflake, Mrs. Lakin, alba, and fimbriata. These are valuable as market Pinks, and in the western and other parts of Middlesex they are grown extensively in the fields, the plantations lasting for a considerable time. Her Majesty is one of the best forcing Pinks, and if the plants have been grown in the open all the summer, they may be potted in the autumn, placed for a time in a cold frame, and then brought gently on in warmth so as to flower in early spring. Then there are the ordinary garden Pinks—Early Blush, Paddington, Lord Lyon, Souvenir de Sale, Anna Boleyn, Ernest Ladlams, and others, which form striking masses in the mixed border. The dwarf-growing, small-flowered, and profuse-blooming Bedford types form a section of themselves; they make a suitable edging to the taller varieties, and the short stiff stems need no tying. For bunching purposes they equal any other variety of Pink. Then there are the florists' laced varieties, which, though chiefly grown for exhibition, are yet, in many cases, excellent border flowers, particularly the varieties Modesty, John Bull, Mrs. Dark, Mrs. Thos. McCrorie, and a few others. It is sometimes said the laced Pinks do not bloom freely, but this is incorrect, as they generally flower with remarkable freedom. A few of the finest laced varieties, from the exhibitor's point of view, will be found in Boiard, Devise, Empress of India, Favourite, Harry Hooper, Miserva, Princess Louise, The Rector, and Zoe. Some excellent varieties are grown in the North, but they are not so well known in the South as they deserve to be. One type of the florists' exhibition Pink—the white-and-black, as it is termed—is, it is feared, becoming extinct. In this Pink no marginal lacing exists, and the fine stout, well-rounded petals surround a dark-coloured centre, and make a striking contrast. To see this type at its best, the flowers require more care when developing than the laced Pinks, and it is prudent to bloom them under glass, and neither sun, wind, nor rain should be permitted to dim their lustre. High cultivation only will produce fine exhibition Pinks. The bed must be prepared by heavy manuring, deep digging and pulverising the clods. The time to plant is the last week in September, or soon afterwards. The bed should be raised above the surrounding level by fully 8 inches in the centre, and fall away to 4 inches at the edge. This is done to secure dryness at the root during the winter. Early planting ensures good root-hold, and there is then less danger of the plants being loosened by frost. Still, it is always well to press the plants down firmly into the soil after a thaw, and before a top-dressing is applied. The sooner in the year the top-dressing can be employed the better. The usual method is to pass horse-droppings and rotten leaves through a half-inch sieve, and when this is applied to place a thin row of sprays of Spruce Fir between each line of plants, and this, standing a little above the plants, protects them from the cold winds of March. This is a precaution that is, however, required more in the North, but it is a sensible precaution in the South notwithstanding. Early in April the branches can be removed, and another similar top-dressing afforded. *R. D.*

LYCORIS SQUAMIGERA.

This Japanese species of *Lycoris* is apparently hardy in the neighbourhood of London. In fig. 38, p. 137, we have pleasure in presenting a view of some plants which flowered at Isleworth, in the garden of Mr. Worsley, to whom we are indebted for the photograph. In an accompanying note Mr. Worsley says that the plants were growing beside an unheated Peach-wall in the open, and that the bulbs received no protection whatever at any time. It is, therefore, a plant well suited for planting in the narrow borders, with southern aspect, that skirt many of the plant-houses in most gardens, and where the *Guernsey Lily*, *Tritonias*, *Montbretias*, and similar bulbous plants do well. *Lycoris squamigera* generally blooms in July or August; the flowers are fragrant, and rose-lilac in colour. The peduncle occasionally grows 3 feet high, and bears generally about five or six flowers in an umbel. The perianth is about 3 inches long, and the tube an inch long. The leaves are produced in spring, and are more than a foot in length, and an inch in width at the centre.

NITRATE OF SODA VERSUS SULPHATE OF AMMONIA.

The comparative value of nitrogen for fertilising purposes in the form of sulphate of ammonia or of nitrate of soda, has been strongly debated in this and other countries, and has been the subject of numerous experiments upon many different kinds of plants, and in different descriptions of soils. Professor Wagner believes that for most crops it will require 100 lb. of actual nitrogen in the form of sulphate of ammonia to produce as large results as 90 lb. in the form of nitrate of soda. In other words, nitrogen in nitrate of soda he considers one-tenth more effective than in the form of sulphates of ammonia. These results seem to confirm the investigations of other experimenters, especially if lime be added with the nitrate. The sulphate of ammonia has very frequently been found to retard or destroy the germination of seeds if they come in contact with it, but there is much less danger from the nitrate. On certain soils, especially those of a light character, a mixture of sulphate ammonia and nitrate of soda is to be recommended.

It must always be remembered that nitrate of soda is more easily washed away into the soil by heavy rains than is sulphate of ammonia, therefore the former should never be applied until there is a crop ready to take it up, as it dissolves in the soil. Liquid manure hastens the germination of most seeds, and has a permanent good effect upon the young plant by the rapidity with which its ammonia gets converted by decomposition into nitrate. *J. J. Willis, Harpenden.*

METHODS OF PROPAGATION.

(Continued from p. 104.)

BY MEANS OF ROOTS.—The herbaceous perennial plants may most be increased by these ready means, as well as by simple division, which is an every-day means of increasing these plants. That which I wish to bring to the notice of the reader is the increase of stock by the denudation and cutting up of the larger roots of some of these perennial plants, which can only be profitably increased in this manner. Some of these plants form nodules or tubers, which are generally stores of starch, intended to provide nutriment for the young plant when making growth in the spring; and just as the hibernating animals lay up abundance of fat before they retire to their long winter sleep, so do some plants store the vegetal analogue of fat—starch. Familiar examples of this are the Potato, the Yam, and the Jerusalem Artichoke. But very many other plants present us with this phenomena in a less marked degree, and thus are with great facility propagated by hitting the plant from the ground, or out of the pot in which it is growing, washing away all the soil from among the fibres, and then with a sharp knife dividing the root into short lengths, each bearing one or two nodes, or, if possible, adventitious buds.

THE SOLOMON'S SEAL.

[or the so-called Chinese Artichoke, *Stachys tuberosa*] will be a good typical plant to begin on, as the mere tyro can see at a glance where to divide them. Each piece of the Solomon's Seal can then be potted or bedded out, and it will make a good plant during the following season, when it will be found a most useful plant, either to force gently for the decoration of the conservatory or border, or to furnish cut spikes for table decoration. Another useful plant, the *Aspidistra* and its variegated forms, now used by thousands for house decoration, and perhaps one of the toughest subjects we have to withstand the effects of close dry rooms and neglect, is increased readily by this method, every leaf or leaf-bud being capable of making a plant when properly treated.

Jannoch of Dersingham, and the Continental growers, by the million, while some are kept in a dormant state by artificial cold, and only brought into use when naturally-grown flowers are out of season.

RICHARDIAS.

This suggests other universally-liked plants, the *Richardias*. These, with the gorgeous-leaved *Caladiums*, the *Alocastas*, and *Anthuriums*, all belong to the same extensive natural order (*Araceae*), and are readily increased by cleansing the roots from all adherent soil, dividing them into small pieces each carrying a bud, which, by judicious treatment, will soon furnish useful plants, merely requiring to be bedded in light sandy soil, and kept moist and warm. As soon as young leaves appear they must be potted on, and if a

among abundance of foliage, whereas selected crowns might be cultivated with even greater facility than those of *Lily of the Valley*. I have no experience of *Astilbe* or *Spiraea latifolia* and *S. Thunbergii*, but should judge them both to be equally amenable to this method of culture; while the lovely *Spiraea palmata* and *S. p. alba* are readily increased by division of the roots, securing good plant and hard crowns for the purpose of potting on and forcing. *Experience*.

(To be continued.)

THE VERBENA.

SINCE the death of our old friend, George Smith, of Hornsey, the *Verbena* seems gradually to have gone out of date; yet in the days of old Tweedman

FIG. 38. —LYCORIS SQUAMIGERA, GROWING IN A BORDER IN MR. WORSLEY'S GARDEN, ISLEWORTH. (SEE P. 136.)

LILY OF THE VALLEY

crowns, which have of late years quite revolutionised the florist's trade in this useful and elegant flower, and in its frozen and retarded buds, furnishes us with good spikes in hitherto untried seasons, are thus manufactured—pardon the word. The roots of *Couvallaria majalis* are fibrous and thick, whilst near the crown numerous adventitious buds form, some of which will produce flower, while others only furnish leaves according to age. By practice, the cultivator distinguishes these one from the other, and separates them by division in 3, 2, and 1-yr. old crowns. The 3-yr. old will bloom the next or the same year, and the others are placed in specially prepared beds of rich sand, lightened by the addition of sharp sand, and the growth is encouraged by liquid-manure and cultivation. Thus treated, they in two or three years develop into the large plump buds or crowns, such as are put on to the market by Mr.

propagating pit be maintained at a cool temperature, a nice batch of plants is obtained. The cultivator who has but a smattering of botanical knowledge will note that all plants of the *Lily* and *Iris* tribes are amenable to this method of increase; but unless he read it he would not imagine that the *White Lily*, the *Yucca*, and the *Dog's tooth Violet* belong to the same natural order, and the climbing *Smilax* to be a very near relative (*Asparagus*).

SPIREAS.

Another very useful flower for the florist is the *Holcia japonica*, called in my young days *Spiraea*, and I am somewhat surprised that this has not been taken in hand by growers, and treated in the same way as *Lily of the Valley*, in order to secure flowering-buds only; whereas now, even the best clumps imported from Holland and Belgium, are not always reliable, giving uncertain and unsatisfactory flower-spikes

and Donald Beaton's famous shot-silk beds, it was one of the gems of the flower-garden. How well I remember the *various* Robinson's *Defiance* caused when it was introduced, this and *Annie*, a purple variety, and later, *Purple King*, carried the palm in their respective colours for some years, and no flower-garden was considered perfect which did not possess these varieties.

Afterwards we became indebted to the late George Smith for a class of *Verbena* better in the size of the truss, and in the greater variety of colour, and for many years the *Verbena* was held in the highest esteem as a bedding plant, and it also used to be successfully grown and exhibited as a pot plant. I believe it will again occupy its former position as a bed- and pot-plant. During the summer of 1896 I saw some lovely beds, consisting both of self colours and mixed colours. We relied too much, until the *Pegonia* came into fashion, on the *Pelargoniums* and *Violas*, and notwithstanding both are well adapted for bedding, yet a change is

desirable, the eye soon gets tired of the sameness, and a greater degree of variety is more pleasing. It is not uncommon in these days to see plants raised from seed; these generally have a more robust constitution, but the beds lack the beauty of the named varieties, for it is impossible to properly mix the colours in unbloomed seedlings so as to be effective. At Enville I used to plant thousands of a bluish variety, called Enville Blue, as the next line to one of yellow Pansies, sometimes in the front line, and *vice versa*, with telling effect; indeed, the Verbena was one of the gems of the flower-garden in those days. I first used yellow Pansies in conjunction with the Verbena at Osberton, where at that time the bedding-out was very extensively carried on, and I well remember the satisfaction it gave to the late Lady Milton. It was at Osberton that *Viola cornuta* and *Fresino* played such a prominent part, not only in the flower-garden, but in the gardening papers. Since those days we have raised *Violas* and *Pansies* of all kinds of shades and colours, but I question whether any of the newer varieties beat the old *Viola cornuta* in its pleasing, lovely, soft tint. I need not dwell on the cultivation of the Verbena, for it is so simple and easy, that almost anyone can grow it, the only art is in the arrangement of the colours, pegging down and regulating the growth. *Edward Bennett, Queen's Road, Egham.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Grafting.—The modes of grafting are numerous, and all of them may be practised with more or less success. Different circumstances, such as size and age of the stock to be operated on, should generally decide the mode to be adopted. I will particularise two methods of procedure which are both simple and efficacious. These are whip-grafting (also known under the names of splice-grafting and tongue-grafting) and rind-grafting, and these are undoubtedly the best modes to follow. The nearer the stock and scion are to each other in point of size, the nearer will be the union. The scions should consist of young, healthy, short-jointed, well-ripened shoots from 9 to 12 inches long, and should, as advised in a previous calendar, be selected, and the butt ends laid in, a few in a bundle, in the soil towards the end of January, the stocks being headed back to the desired point a few weeks later. In proceeding with the operation, insert the knife in the stock 3 or 4 inches from the top, and cut off a wedge-shaped slice of wood in an upward direction, nearly halving the stock (if a small one), at the top sloping; the remaining portion off to the bark immediately above a wood-hud. Then make a cross-downward notch at the base of both oblique cuts, making corresponding cuts in the scion, both transverse cuts in this case being made in an upward direction to enable the latter being tongued into the stock in the process of grafting (see Fig. 39). The stock and scion should be prepared with a sharp knife to ensure clean even cuts being made, so that the wood and bark surfaces shall fit closely together. The scion having been thus fitted to the stock, it should then be bound therewith with a band of raffia, beginning at the bottom and finishing at the top, where the matting should be made secure. This done, cover the matting with clay (to which a small quantity of cow-manure may be added) of the consistency of putty, making it firm, full in the middle, and tapering off at both ends. This will exclude air and rain, and yet preserve the graft in a moist state.

Rind-grafting is not only simple and efficacious, but also an expeditious way of propagating the Apple, Pear, Plum, and Cherry. Spawd grafts of these fruits fall, budding can be had recourse to in July and early in August. Indeed, this method of propagation is the one generally practised in the case of Apples, Peaches, Nectarines, Cherries, and Plums. Rind-grafting consists in making a longitudinal cut in the rind to the depth of about $\frac{1}{2}$ inch from the top of the beheaded stock, and in raising the bark or rind on either side of this cut with a pencil-like stick, rounded at one end and feather-edged, and pressing therein a scion of similar dimensions. The edges of the bark on each side should then be brought close to the graft, bound round and clayed as recommended above. Where there are several hundreds or thousands of young stocks to work, two pairs of hands are generally employed in doing the work—one in putting in the grafts, and the other binding and claying them as indicated.

THE KITCHEN GARDEN.

By W. PORE, Gardener, Highgate Castle, Newbury.

Asparagus.—When a sufficiency of established roots of *Asparagus* is at hand, a few dozen roots may be lifted, and placed in a frame over a gentle hot-bed. Care must be taken to lift the roots with plenty of soil attached to them. Place a few inches of leaf-mould over the warm manure, and then put in the clumps closely together, and sprinkle over them a little fine soil. Give them a good watering with tepid water, and afterwards add 3 or 4 inches of soil evenly over all. The frame may be covered with mats or litter until the tops begin to show through, which will probably be in about a week. Plenty of light and air should then be given, and the produce will be equal in quality and appearance to that grown out-of-doors. Old plantations that may not yet have been put in order for the season, should be given a good dressing of rich, well-decayed manure, which may be forked lightly in, but care must be taken not to injure the crowns or roots in any way. A good sprinkling of salt may be added to the manure with advantage, especially on light, dry soils.

Seakale.—New plantations of Seakale may now be made from the largest side-roots cut into lengths of 6 or 8 inches. These sets are usually prepared at various times during the winter, and laid in on a border out-of-doors until required for planting. If this has not been done, prepare the sets at once by cutting the top end of the root straight across with a sharp knife, the bottom being cut at an angle, so that no mis-

FIG. 39.—TONGUE OR WHIP GRAFTING.

take as to the position of the root be made when planting. A deep, rich, cool soil is the best for this vegetable, and the sets should be inserted with the tops just below the surface, at a distance of 1 foot or 15 inches from each other, and in rows 2 feet apart. When growth has commenced, examine them carefully, and reduce the number of shoots to one or two on each crown. If it is intended to plant in permanent beds for forcing on the ground, the sets should be planted in clumps or bunches of three, in a radial space of 8 or 9 inches, that they may be conveniently covered with the pots in use, and 2 feet each way between the groups is a suitable distance. The variety known as Lilywhite is much superior to the old purple variety in appearance and quality, though not quite so hardy, as it requires a slight covering of litter or Ferns over the crowns during severe weather.

The Main Crop of Onions.—If there be favourable weather, and the ground is in good working condition, there is no better time than the end of February or early in March for sowing Onions for the main crop. An open, sunny site should be chosen and, if possible, one which has been well manured and deeply worked previously. Pig-dung or other such rank manure should never be used for this crop, or it will almost certainly cause an attack of the Onion fly. The ground should be well manured for Celery is very suitable, and no fresh manure is needed; but it should have been roughly dug, and well exposed to the winter frost. Take advantage of a dry day to fork the ground over thoroughly, and when it can be walked on without

sticking to the feet, tread it firmly all over. Apply a good dressing of fresh soil before drawing the drills, which should be a foot apart and $\frac{1}{2}$ inch deep; sow the seed thinly, cover with fine soil, and rake over the surface neatly. A good selection of James's Keeping, Reading Improved, Banbury, Vaitch's Main Crop, and the Wroton are reliable and good Onions.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Dropprog, Maidenhead.

Hollyhocks.—Owing to a disease affecting the plants for many years past, this hardy and showy perennial has fallen out of general cultivation. The usual method of propagation by cuttings of the young growths, slipped off with a heel, is now not much practised, plants raised in this manner seeming to be more susceptible to attack than seedlings. The best method of ensuring a good display is to treat the plant as an annual or biennial, and if the seeds are obtained from a trustworthy source, a good percentage of double-flowered spikes may be secured. If treated as a biennial, the seeds should be sown in the month of August, and the plants wintered in a frame, secured from frost. Equally good results may, however, be obtained from seeds sown in early spring, if the plants are properly attended to from the first. Sow the seeds thinly broadcast in pans or boxes filled with a soil consisting of equal parts of loam, leaf-soil, and a small quantity of sand, and merely cover the seed with finely-sifted soil. After sifting the soil a moderate amount of water placed in a mild hot-bed frame having a top-heat of 60° to 65°, and covering the pans, &c., with thick brown paper till the seedlings appear. As soon as large enough to handle prick off into other boxes, or pot singly into small 60's, returning them to the hot-bed, which should be so made up that the plants come near to the glass; shade from bright sunshine for a few days. When well rooted place them in a cold frame, and keep close for a time, and then admit air, cautiously affording more and more as the season advances. Plants which make good progress may be shifted into 4½-inch pots, and by the middle or end of the month of May they will be fit for planting out in the beds or borders. The stations for Hollyhocks must be heavily manured and trenched, or if in a bed, the whole of it should be so treated. In dry weather a mulch of half-decayed dung and plenty of water should be afforded. With this kind of treatment the Hollyhock flowers the first year.

Marvel of Peru.—This is a half-hardy perennial, growing to about 2 feet in height, and is a useful plant for dotting about in herbaceous borders. The tuberous roots are stored like those of the Dahlia, and may forthwith be potted and stood in a greenhouse or garden-frame, excluding frost and encouraging a slow sturdy growth. Several varieties, with brilliant colours, may be obtained from a packet of seeds, or assorted colours may be purchased, if that is preferred. If seeds be sown at this season and the seed-pots placed in heat, good plants may be raised in readiness for planting out as soon as all danger from late frosts is past. The pots may be filled with a light kind of loam, and the seedlings potted singly as soon as they are large enough to handle. Old roots are the best for forming large clumps.

Dolphins.—The propagation of named varieties of *Dolphins* is easily effected at this season by slipping off the young shoots with a heel, now starting from the base of old stools, which, when potted into small pots, filled with sandy loam and leaf-soil, and stood in a cold frame, soon form roots. They may be planted in the borders in April. This is the best method to increase named varieties, and the young plants produce fine flower-spikes the first season. It is a more satisfactory method than dividing the old stools and replanting them at once in the border. Seeds may also be sown, and of the single and double-flowered varieties the treatment afforded being similar to that advised for raising Hollyhocks.

THE ORCHID HOUSES.

By W. H. WHITE, Orchard Gower, Burford, Iorking.

Anacochilus.—The present is a suitable time to divide and rearrange specimen plants of *Anacochilus Dandonianus*, *A. petala*, *A. rollinsonii*, *A. Lowii*, *A. striatus*, *A. Roxburghii*, *A. setaceus*, &c. Exceptional care must be taken not to injure the roots, for if the point is damaged the young shoots will cease to grow, and will it produce lateral roots, as many of the orchids do. It will be found that the rhizomes have become too long to be again planted in pots of convenient size, therefore cut the rhizome in two, and leave several roots attached to the leading growths. Each of the pieces should then be put separately into

the smallest pots convenient, and plunged as closely together as they will stand in shallow pans filled with growing sphagnum-moss. The rooting material should consist of finely chopped sphagnum-moss, a liberal quantity of coarse silver-sand, and some small, clean crocks. Place the plants in a shady part of the stove or East Indian-house, and put an ordinary bell-glass with a hole at the top over them. This hole should be stopped with a cork, and until the plants have become re-established it should be kept close during the greater part of the time. When young leaves and roots commence to show, the bell-glass may be tilted a little, and the cork removed during the day-time, but at night the glass should be quite closed. Take the glass off each morning, and wipe the interior thoroughly dry. Keep the plants moderately moist at the root whilst growing, and shade them carefully from strong sunshine, but otherwise admit as much light as is possible.

Masdevallias.—In the intermediate-house, plants of the Chimera section of Masdevallias, as *M. chimera*, *M. bella*, *M. Nycteria*, *M. Roezlii*, *M. Winniana*, *M. Wallisi*, *M. Backhouseana*, *M. Houtteana*, *M. Carteri*, *M. radiana*, *M. Chesteroni*, *M. aculeata*, and *M. erythrocheta* are now commencing growth; it is, therefore, an excellent time to divide old plants, or to give more root room to any that require it. All of the varieties enumerated should be grown in open Teak-wood baskets, and as their flowers grow in a downward direction, no crocks should be used for drainage; only a moderate quantity of peat and sphagnum-moss is needed for them to root in. For the next two or three months these species may be suspended in a well-shaded position in this house. After the plants in it are not good practice to give them a thorough watering; an occasional sprinkling, in sufficient quantity to keep the compost moist, is preferable. Take down the plants on bright mornings and well syringe the under-sides of the leaves with tepid soft water. The pure white *M. tovensis* is also starting to grow, and it is a good time to repot them. Pots or pans may be used, and should be filled to within an inch of the rim with drainage material, covering it lightly with a layer of sphagnum-moss. This species will root freely in equal parts of sphagnum-moss and peat, which should be kept moist only, and the young leaves are well advanced. The leaves of this Masdevallia should be sponged over occasionally, as they are often attacked by small yellow thrips. Unlike most other Orchids, the old peduncles, if allowed to remain on the plant, will bloom for two or three consecutive years; but the retention of these spikes is not advisable, as in time the energies of the plant become weakened. The coolest part of the intermediate-house suits the plant at the present time.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Ho., Luton.

Chrysanthemums.—As soon as it is seen that the roots are showing through at the sides of the ball, re-potting should be undertaken. The pots made use of should be either new or well washed, and the re-potting done firmly. Replace the plants in the cold-house or span-frame, affording no heat unless it be to exclude frost, and afford less air than previously for a period of one week, which will be about the time required to re-establish them afterwards gradually increased the amount. An ordinary cold-frame will answer well enough if it be stood on a bed of coal-ashes, and covering is at hand in case of need. A frame has its advantages, in that in mild weather the lights can be drawn off, but in bad weather the plants are apt to suffer from dampness, and for choice then a greenhouse is the best place. The aim of the gardener should be to secure sturdy and continuous growth, and for this reason crowding the plants must be always avoided. Fumigate the plants now and then, doing it when the leaves are dry.

Achimenes.—A batch of tubers may now be started, and to prolong the flowering season of the plant, batches may be put in at fortnightly intervals. They may be placed in the flowering-pots at first, the latter being extra well drained, and a compost used consisting of one-half sandy-peat, one of leaf-mould not too much decayed, and a small quantity of dried cow dung rubbed through a small-meshed sieve. Place the tubers evenly over the surface of a 7 or 6-inch pot or deep pan, and cover them over with a 1-inch layer of the soil. To start the tubers, a temperature of 60° by night, and 65° by day, is necessary. The soil should be lightly sprinkled till the plants commence to show flower, when wetting the leaves should cease altogether.

Hyppocastanum (Amaryllis).—The whole of the flowering-bulbs will now need to be repotted. The larger ones should have all the soil shaken from the roots, and be repotted singly in 6 or 7-inch pots, according to size of bulb, using as a potting-mixture rich fibrous loam four parts, dried cow-dung one part, and peat one part. Afford the newly-potted bulbs a thorough watering, and after allowing the water to drain away, plunge the pots to the rims in a bed of cocoanut fibre refuse, or some other plunging material, over a mild hot-bed of tan or hot-water pipes. Very little water will be needed before growth is advanced. A temperature of 50° by night, with a rise of 10° to 12° by day, will suit them for the first month after repotting. When the flower-spikes begin to push (which should be a little in advance of the leaves), the temperature may be raised to suit the season the flowers are wanted for. Maintain a nice growing atmosphere in the house, syringing the foliage to favourable weather, and shutting up the house early in the afternoon.

Eucharis.—Plants that are just passing out of flower require copious root-waterings, and if the pots are very full of roots, and the plants have not been potted for several years, they will be much benefited by weak manure-water given twice a week. Clear root-water may be given them at any time—it is always helpful; and if the plants are syringed with it occasionally they will be the better for it. The *Eucharis* does not require the high temperature some growers are apt to give it. No bottom-heat is given the plants here, nor do we use artificial manures. The stock has not been re-potted for over six years, and the plants give three lots of bloom each year. They are never dried off, but they are rested. At present a temperature of 55° to 60° by night will suit healthy specimens passing out of flower. Syringe them well early in the afternoon. Afford a little air on all favourable occasions, and shut up with plenty of sun-heat when possible.

Bulbs.—Examine all bulbs that are still in ashes or other such material, and do not allow them to remain there too long.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Easton Castle, Leithway.

Tomatoes.—The earliest plants being now sufficiently large to be placed in their fruiting-pots, should be potted before becoming root-bound, as to let them get into this state is to seriously check their growth. This also will result from placing them in a lower degree of warmth without first inuring them to it; and by the application of water at a low temperature. It is very essential that the pots and soil should be warmed before proceeding to repot. When the flowers begin to expand and the plants are established, more air will be necessary for securing a good crop. During flowering the plants should be kept somewhat on the dry side till a good set is obtained, afterwards more warmth may be applied; also top-dressings of decayed manure and soil, affording warm liquid-manure freely. At Easton the early crops are obtained from plants grown in rough troughs about 14 inches wide and deep, the plants being placed at the bottom of these troughs, with enough soil to just cover the balls, which allows plenty of space for top-dressings. They stand at about 16 inches apart, and are run up as single stems at first, then a second shoot comes out at the base of the plant; it runs up, so as to give a succession of fruits. This method of cultivation is less troublesome than if pots were used, and is a saving in many directions. Later batches of plants should be repotted as occasion demands, keeping them sturdy. Seed may be sown forthwith for late fruiting under glass and outdoor culture, sowing thinly and potting off the seedlings as soon as they can be readily handled.

Cherries and Plums.—The earlier-started trees, now that they are in flower, should have free ventilation night and day in favourable weather, and be gently tapped to distribute the pollen. The soil in the pots must be kept moderately moist at this season, as any failure to do this will be sure to cause the fall of the bloom. After this date all portable trees should be in their places. These planted in the beds and borders should be examined as to the state of the soil, and where this is found to be dryish, it should receive a thorough application of water. The glass and woodwork of the house should be cleansed, and borders cleared of rubbish and top-dressed. On sunny days the trees should be wetted with the syringe, no artificial heat being applied in the early stage unless it be required on frosty nights when the trees are in bloom, or in dull or rainy weather. If

the house be unheated, it should be kept cool and the trees at rest till the latest period possible. In any case after the trees one good fumigation before the flower-buds burst.

Early Pot-Vines.—The Grapes on November-started Vines will now be stoning, and ought not to be much pushed along, for although seemingly at a stand-still whilst the seed is in course of formation, growth will soon become more apparent. Be careful to affording water at the root, never allowing the soil to become dry, as one mistake of this sort would be very injurious. Stop the lateral shoots to a moderate degree, and keep growth somewhat thin. When the berries re-commence to swell, the temperature may be increased by degrees from 65° to 70° at night, with a commensurate rise of 10° by day. Close the house or pits early in the afternoon, damping the paths, walls, &c., at that time. When the colour is noticed in the berries, let the louse be kept rather cooler, and although it be closed as early, a small quantity of air should be admitted about 6 P.M. If this practice be adhered to, the colour and finish of black Grapes especially will be much improved.

Late Vines.—The Vines should be started about the first day of March, the fruit requiring a longer season to arrive at maturity than they do when the vines started earlier in the year. The ripening should be finished by the end of the month of September. The temperature at the start should not exceed 50° by night and 60° by day. Afford the border inside the vinery a good application of water at a warmth of 85°; syringe the Vines twice daily in sunny, and once only in dull or showery weather.

THE APIARY.

By EXPERT.

The Brood-chamber.—It is yet too early to make an examination of the combs by breaking up the brood nest, though some who have passed the novice stage in their career as bee-keepers have done so, and unwisely have made the fact known. I say unwisely, because what such bee-keepers do, the novice thinks he may attempt—but the practised hand knows what the novice has to learn, first, that the less the brood-chamber is interfered with the better at all times, but particularly when the low temperature prevailing around is likely to chill the brood; and secondly, how to do such a delicate operation in what would of necessity be a double quick time to avoid the consequences of a chill, or by my own part, I like to advise what I do myself, and at present, I shall leave the brood-chamber severely alone. But though the combs ought not yet to be pulled apart for the necessary spring examination of combs, brood, and queen, the larider must be replenished if the food-supply runs short. Economy of heat is a great desideratum in the early months of the year, and so I would advise the removal of the outer combs not covered with bees, their places being taken by dummies. At the same time, whether stores are short or not, a two or three-penny cake of soft candy may with advantage be placed upon the frames. Over all, then, place as much covering in the shape of woolen wraps as the loft will hold, and then, as soon as the weather will permit of the overhauling of stocks, a crowded brood chamber and extensive patches of brood will prove the wisdom of present attention. When breeding operations commence, there will be innumerable bits of comb and other debris falling to the floor-board, which, however, should not be allowed to accumulate. I have seen stocks many a time with such accumulations on the floor-board nearly 1 inch in depth. How much nicer and how much better for the health and prosperity of the community would it have been if, as soon as a spell of fine mild weather came, the floor-boards were carefully removed, scraped, and dried. There are many stocks in which the combs have been built every way but the right way, thus making movable combs a misnomer; and now is the time to set about remedying the defect without wholly upsetting the colony. The bees will be confined at present to the centre combs, therefore advise the outer two or three combs, more or less, being cut apart quickly so as to leave the bees crowded by dummies upon just as many of the crooked combs as they can well cover. New combs or frames of wired foundation may then be added as required, being careful to gradually push the few irregular combs now left to the back or side. The queen will in due course leave them for the nice new combs at the side, and then, if it is thought desirable and time will permit, the bad combs may be replaced with fresh ones as soon as the brood hatches.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR MARCH.

- WEDNESDAY, MAR. 3.—Devon and Exeter Gardeners' Association Meeting.
- THURSDAY, MAR. 4.—Linnean Society Meeting. Ayrshire Gardeners' Meeting.
- SATURDAY, MAR. 6.—Soc. Franc. d'Hort., London. Isle of Wight Hort. Imp. Soc.
- TUESDAY, MAR. 9.—Royal Hort. Soc. Coms.
- WEDNESDAY, MAR. 10.—Renfrewshire Gardeners' Society.
- SATURDAY, MAR. 13.—Royal Botanic Society Meeting.
- WEDNESDAY, MAR. 17.—Devon and Exeter Gardeners' Soc., Spring Show.
- THURSDAY, MAR. 18.—Linnean Society Meeting. Royal Soc. of Horticult. and Botanic Gdns., Birmingham (two days).
- TUESDAY, MAR. 23.—Royal Hort. Soc. Coms.
- SATURDAY, MAR. 27.—Royal Botanic Soc. Meet.
- TUESDAY, MAR. 30.—Truro Daffodil Show (two days).
- WEDNESDAY, MAR. 31.—Royal Bot. Soc., Spring Show.

SALES.

- MONDAY, MAR. 1.—Roses, Herbaceous Plants, Lilies, &c., at Protheroe & Morris' Rooms. 1000 lots of Border Plants, Roses, Climbers, Ornamental Shrubs and Trees, Lilies, Hardy Bulbs, &c., at Stevens' Rooms.
- TUESDAY, MAR. 2.—Hardy Ferns and Grasses, Gladioli, &c., at Protheroe & Morris' Rooms. Japanese Lilies, Azaleas, Gladioli, Palms, &c., at Protheroe & Morris' Rooms. 3000 English, German, French, and Dutch Roses, Ornamental Shrubs, from Holland, English and Foreign Fruit Trees, Palms, Border Plants, &c., at Stevens' Rooms.
- WEDNESDAY, MAR. 3.—Herbaceous and Hardy Plants and Bulbs, Carnations, &c., at Protheroe & Morris' Rooms. Trade Sale of Lilliums, Bulbs, Roots, &c., at Stevens' Rooms.
- THURSDAY, MAR. 4.—Imported and Established Orchids, at Protheroe & Morris' Rooms.
- FRIDAY, MAR. 5.—

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick:—40° 8'.

ACTUAL TEMPERATURES—LONDON.—February 24: Max., 51°; Min., 47°. PROTHEROE.—February 24 (6 P.M.): Max., 52°, Valencia Min., 44°, Orkney.

The Royal Gardeners' Orphan Fund. In another column we give a full statement of the doings at the annual meeting of this most useful institution. It was established ten years ago to mark the Jubilee of our Queen, and to fill up a vacancy in our charitable institutions. Its inception was due to gardeners, its

foundation was completed by gardeners, it has hitherto been maintained mainly by the exertions of gardeners, its benefits are extended exclusively to the orphans of gardeners. Need more be said to recommend it to the continued assistance of the gardeners of all degree. We are told that works of mercy and charity commend themselves most to our Queen as the means of commemorating the completion of the sixtieth year of her reign. This is exactly in accordance with what we know of Her Majesty's feelings. To strengthen and extend the Gardeners' Orphan Fund, established in 1887 in commemoration of the friendly meal which followed the work of her Jubilee is surely as fit a thing as we can do, and we do not think we can urge that duty more forcibly than by quoting the words of Her Majesty's gardener, Mr. OWEN THOMAS, on the occasion the anniversary meeting:—

"It seems but yesterday that we were celebrating the Jubilee year of Her Majesty's accession to the throne. It was on this occasion when gardeners, like other loyal members of the community, were looking out for a means to give expression to their loyalty, that it occurred to Mr. PENNY, then of Sandringham, and Mr. CLAYTON, of Grimston Park, that the best mode this expression could take would be the institution of a Fund to befriended the orphans of gardeners. I cannot but think that both these gentlemen will always look back with feelings of thankfulness for the inspiration that came to them to suggest the institution of this Fund. At first the idea was met by much misgiving by many as being too great an undertaking to be successfully launched; however, there were a few bold spirits in those days, and the project was no sooner ventilated by the gardening Press than it was taken up by acclamation, not only by horticulturists, but also by the garden-loving public, and the proud position the Fund occupies to-day proves beyond doubt that a happier or a better suggestion could not have been made. So much for the inception of the Fund. What then shall be said of its growth? The excellent report in the hands of members will tell them much better than I can. But I may be allowed to say this—that nearly 45000 has been paid to destitute orphans of gardeners during the past nine years, besides which a sum of £2000 has been invested for their future benefit. This is a record to be proud of, and the management may be congratulated. This great success has been brought about, in the first place by virtue of the merit of the charity—gardeners' orphans.

"The English people love their gardeners, and they have opened their hearts and their pockets wide to help the objects of this charity. We know that our happy and favoured country is full of benevolent and kindly feeling towards the weak and the destitute. But it is not everyone who has the power or the faculty of being able to bring this good quality into active existence. The orphan fund is fortunate in having those at its head who take an active, personal, and practical interest in its welfare. When it is said that at the head of the charity we have H.R.H. the Princess of WALES, with His Grace the Duke of BEDFORD, as President; our esteemed friend, Mr. MARSHALL, as Chairman of the executive committee; with our old friend, Mr. BARRON, as Secretary; besides a working committee of gentlemen, everyone of whom is a well-known horticulturist; the success which has attended the establishment of this Fund is not to be wondered at.

"We must not forget that the establishment of this Institution has imposed a serious responsibility on those who are responsible for its management and maintenance. To-day there have been added thirteen orphans to share the benefits of the Fund, at an extra annual expenditure to the charity of £170. A better commemoration of Her Majesty's long reign no Institution could possibly make, but in view of this greater responsibility a greater income must be forthcoming, or the Fund will be in the

same position as the orphans are now in—namely, "with no provision." If you will look down the list of orphan candidates for election, you will find the melancholy words, "no provision," "no provision," repeated over and over again. To me those words express a feeling of utter despair and desolation, as represented in the case of the widow and destitute orphan. It means to them not only an empty chair, but an empty cupboard, an empty grate, and often worse than all—an empty heart. The object of this charity is to help to ease the widow's burden, and to brighten the path of the orphan child. The wealthy lovers of gardens and gardening, as well as members of the horticultural trade, have come out nobly to help the garden charities—both this one and the older charity—in the welfare of which most of us are also deeply interested. But it is with regret, and I say deep regret, that the fact must be stated that gardeners generally have not rallied round and identified themselves with the welfare of the garden charities as they ought to have done. I don't know why. It is not from the want of kindly thoughts and feelings, I am quite sure, and I don't think it can be from the want of 5s. a year. Let each one of those who have not subscribed answer for himself this eventful year, in the best of all ways, by sending in his subscription to Mr. BARRON. What we want is, that both the garden charities should become in reality national garden charities. They should embrace the name of every gardener worthy of the name throughout the land, so that those who do not support the charity may be an exception and not the rule, as at present. We must gratefully acknowledge the valuable and increased help given by our earnest and kind gardening friends in the provinces, and on their continued valuable help must largely depend the future welfare of this charity. But the greatest source of our strength as regards the future, must, I think, lie with the rising generation of young gardeners. To make it easier for them to join the Institution, may I suggest, if your rules will permit of its being done, that you reduce the subscription of young gardeners to 2s. 6d. a year (noble shillings are potent in charity), and if this can be done, I would ask every gardener who has the interest of the charity at heart to bring the subject before his young men, when I am sure a liberal response would be the result. This would open an easy door of entrance to the young, and ones you secure his interest and sympathy, you may depend upon it that in the great majority of instances, he will prove a steadfast friend and supporter of the Fund, and at the same time become a better gardener.

"It cannot be too well known that this is a purely benevolent institution, and that no question is asked as to the nationality of the applicant for its help, or as to what religion their parents may have preferred, neither are the orphans barred from the benefits of the fund if their fathers in their lifetime have been so neglectful as to fail to support the Institution. At the same time, I cannot help saying that I would not give much for that man's love or care for his wife and children who refuses to do what he can whilst in health for an institution on the funds of which those who are near and dear to him may be compelled to throw themselves through death and misfortune."

FLOWERS AT KENSAL GREEN CEMETERY.

Those who know this large burial-place in the west of London may also have some idea of the difficulties that attend plant-culture there, owing principally to the presence of several very large gasometers. The fumes that occasionally escape from these have a very serious effect upon tender plants, and sometimes cause the leaves to drop in great quantity. We have pleasure, therefore, in presenting a view of a group of plants that was to be seen in one of the houses at the end of last summer (fig. 40), as the *Dracaena*, *Celastrus*, and other species exhibit successful cultivation, more than equal to what one would expect. Mr. T. EBROSS has had charge of the cemetery for about two years, and during that time has effected considerable improvement

FIG. 10.—A GROUP OF MISCELLANEOUS PLANTS GROWN IN THE STAIRS OF 1896 IN A GREENHOUSE AT KINSAID GREEN GALLERY.
(SEE P. 140.)

in its appearance, many of the paths having been re-made, and two new plant-houses erected last year. There is a total area of nearly 100 acres, and consequently several miles of drives and paths to maintain in condition. For garden purposes there is retained a staff of twenty men, and during the summer the cemetery presents a neat and pretty appearance. It has a nice central avenue of Lime trees.

LINNEAN SOCIETY.—An evening meeting will be held on Thursday, March 4, at 8 P.M., when the following papers will be read:—1, "On a Trichoderma Parasitic on *Pellia epiphylla*, Corda," by Mr. W. G. P. ELLIS; 2, "New Species of Poricheta from New Britain, &c.," by Dr. W. B. BENHAM.

BRUSSELS ORCHIDÉENNE.—At a meeting of the Brussels Orchidéenne, held on Sunday, February 14, MM. LUCIEN LINDEN & Co. exhibited a fine selection of Orchids. Specially noteworthy were two *Odontoglossums*, which were commended by the jury; *O. crispum* var. *Kegejani*, a fine type of "Pacho," with well-rounded flowers, the ground faintly tinged with straw colour, and spotted all over with bright brown-red; *O. c.* var. *mirabile* has flowers of a citron-yellow hue, cultivated by effective white lines; it forms a distinct and valued variety. There were also a dozen varieties of *Cattleya Trianei*, *di primo cartello*, viz., the wonderful *C. Trianei* var. *Imperator*, not shown for competition; as well as the exceedingly beautiful *C. T. excellens*, *C. T. princeps*, *C. T. majestica*, *C. T. Ragotiana*, and others not yet named. M. RAGOT DE MEAUX showed a variety of *Odontoglossum Wilkeanum*, much spotted with clear chocolate-brown; M. PAUWELS sent an excellent *O. crispum*, three fine varieties of *Cattleya Trianei*, *Oncidium splendens*, very well flowered; and *Cypripedium* Mrs. Canham. M. MIFEAU exhibited a pretty *Cypripedium exul*, and a strong, well-flowered plant of his beautiful *C. Pauli* var. *superbum*. M. COPPENS had a series of fine varieties of *Cattleya Trianei* and *Odontoglossum crispum*, with nicely-rounded flowers, possessing a few small spots. M. DE LOMBAERDE showed a dark variety of *Lælia anceps*, Dr. CAPART a good variety of *Cattleya Trianei*, the lip developed and well coloured, and a well-bloomed *Dendrochilum glaucum*. The Royal Gardens at Laeken were represented by a delicate variety of *C. Trianei*, with small but nicely-coloured blooms; M. LE CHEVALIER DE WARONY sent several remarkable varieties of *C. Trianei*; M. LINDEN showed a fine group, including fine specimens of *C. Trianei*, and *Odontoglossum Wilkeanum* and *luteo-purpureum*, nicely marked; and *Cypripedium Lebdaudayanum*, which had been before shown, was again admired. The jury made the following awards:—First-class Diplomas of Honour (for new Orchids) for *Odontoglossum crispum* var. *Kegejani* (*par acclamation*), and *O. c.* var. *mirabile*, a *Uraninié* (sic), both from MM. LUCIEN LINDEN & Co. First-class Certificates of Merit (for fine varieties) were awarded for—*Odontoglossum Wilkeanum* var. *leopardinum*; to M. LINDEN, a *Uraninié* (sic), for *Cattleya Trianei* var. *excellens*; to MM. LUCIEN LINDEN & Co. (a *Uraninié* (sic)); for *C. Trianei* var. (two) to M. COPPENS, both a *Uraninié* (sic); for *C. Trianei* var. *princeps*, to MM. LINDEN & Co., a *Uraninié* (sic); to M. MIFEAU, for *Cypripedium Pauli* var. *superbum*; to M. COPPENS, for *Cattleya Trianei* var.; to Dr. CAPART, for *C. T.* var.; to M. LUCIEN LINDEN & Co., for *C. T.* var. *majestica*; to M. LINDEN, MM. LUCIEN LINDEN & Co., and M. LE CHEVALIER DE WARONY, each for *C. T.* var.; to M. DE LOMBAERDE, for *Lælia anceps* var. *Léda*; to M. LINDEN, for *Odontoglossum Wilkeanum*; to M. MIFEAU, for *O. crispum*; to M. LINDEN, for *C. minus*; to M. COPPENS, for *C. O. crispum* var.; and to M. LINDEN for *Saccolabium guttatum* var. *album*. Second-class Certificates of Merit were awarded for the *Cattleya Trianei* of M. COPPENS, M. PAUWELS, and (a third) again to M. COPPENS; and to M. LINDEN, for *Odontoglossum luteo-purpureum*. Certificates for flowering were allotted for *Dendrochilum glaucum*, from Dr. CAPART; and *Oncidium splendens*, from M. PAUWELS. Messrs. HUGH LOW, of London, showed at this meet-

ing their new crested *Cyclanum*, *Dash Hill Pioneer*, which has white flowers, and is very beautiful; the jury awarded it a First-class Diploma of Honour (it was not for competition) *à l'unanimité*.

CACTACEÆ.—Dr. KARL SCHUMANN, of the Royal Botanic Museum, in Berlin, is about to bring out an illustrated monograph of the Cactaceæ, with cultural notes by M. KARL HUBSCHER. The work will be published in ten parts, at 2 marks (shillings) each. The publisher is Mr. J. NEUMANN, of Neudamm, but the work can be procured through Messrs. WILLIAMS & NORBATE, Henrietta Street.

MR. DAVID THOMSON.—Some of Mr. THOMSON'S old pupils have availed themselves of his retirement, as affording them a fitting opportunity of manifesting their appreciation of his services to horticulture, and of their gratitude for his interest in their welfare. Mr. A. HENDERSON, Thoresby Park Gardens, near Ollerton, Notts, has the matter in hand, and to him all communications should be addressed.

DEVON AND EXETER GARDENERS' ASSOCIATION.—On the occasion of the meeting of the above, at the Guildhall, Mr. W. SWAN, of Blystock, in the chair on Wednesday, February 17, Mr. T. BUCKBANK, late Orchid foreman at Mentmore, Buckinghamshire, gave a lecture on "Orchids and their Cultivation." He began by reviewing the erroneous methods of cultivation pursued by the early cultivators of Orchids in this country, pointing out that many of their mistakes arose from ignorance of the climatal conditions under which Orchids existed in their native habitats. He then contrasted the present successful methods of culture with what were formerly held, and primitive Orchid-houses with modern ones, and gave reasons why roomy houses are to be preferred to small, close, ill-lighted ones, in which Orchids, as well as other species of plants, used to be grown. Ventilation, temperature, water, composts, &c., were then successively dealt with; also, the use of manures, and the employment of Jarofo-fibre in Orchid culture.

THE HAMBURG EXHIBITION.—The prospects of the approaching International Horticultural Exhibition at Hamburg are highly satisfactory. The scientific and other sections are assured of success, and valuable prizes are offered. Congresses will be held during the course of the exhibition; in August many gardeners are expected to muster, to discuss professional interests, and study the various exhibits. Entries for the spring show should be made (addressed to the Organising Committee) before the end of March.

—The amount of interest shown by foreigners in the exhibition is exceeding all expectations, and quite recently the exhibition authorities have been the recipients of an official communication from the Government of South Australia expressing a desire to take part in the exhibition. The Cape of Good Hope authorities have telegraphed for a programme and full particulars, so as to be in a position to afford information to intending exhibitors from that colony. Mexico has taken similar steps, and a wonderful collection of *Cacti* is to be sent from that country. California is sending a Commissioner and several assistants. Its exhibit includes three large railway waggons, such as are employed in the conveyance of fruit.

"THE CANADIAN HORTICULTURIST" appears this month in a new and much improved guise. Though fruit culture is still a principal feature, other departments of horticulture now receive more attention than formerly, and attend, together with the improvements in paper and type, that horticulture is attracting more general interest than heretofore. The journal is printed and published at Grimsby, Ontario.

TADCASTER PAXTON SOCIETY.—On February 15, Mr. W. CALLEN, B.A., read a paper on the "Flora of the Ergone Ages." He first reviewed the history of the birth from its incandescent condition,

through its successive stages of igneous and sedimentary rock-formations; and the flora of the carboniferous period was dealt with in detail. A rich collection of fossils was afterwards inspected.

MANNA FROM GRASS.—At a meeting of the Royal Society of New South Wales, in December last, Messrs. BAKER and SMITH announced the discovery of a substance like manna on the nodes of a grass, *Andropogon annulatus*. The excretion occurs in masses of the size of a marble.

SWEET PEAS UP TO DATE.—Messrs. W. ALLEE BURFEE & Co., of Philadelphia, have published a little pamphlet under this title. From the interesting statements and historical data it includes, it is something more than a trade catalogue. The author of the brochure is the Rev. W. T. HUTCHINS, who gives details as to culture, and a descriptive catalogue of 165 varieties, mostly raised by Messrs. BURFEE & Co., or by our renowned champion H. ECKFORD, to whose efforts it is that the present fancy for these sweet flowers has attained such large proportions. It is to be hoped that the florists will not be too severe in their coil of properties; already there is a tendency to flatten petals, remove notches, and render the flower formal. The flower is naturally irregular, and to make it anything else may be curious, as showing what may be done; but it is a mistaken taste, and wipes away all the history and meaning of the flower.

ANTON JELINEK.—We glean from the *Wiener Garten Zeitung* for February 15, tidings of the death on January 6, the present year, of ANTON JELINEK, a celebrated Bohemian gardener, and the creator of the fairy-like, imperial gardens of Miranar and Lacornar; and later established as a nurseryman in Dobling, near the Austrian capital. He was chosen by the Imperial and Royal Academy of Sciences for his botanical acquirements, to accompany the *Novara* frigate in her three years' voyage round the world. For his services on this expedition he was decorated by the Emperor FRANZ JOSEPH with the good service order of the Golden Cross with the Crown, on the recommendation of Dr. EDUARD FENZL, the then Director of the University Gardens of Vienna.

ENGLISH ORCHARDS.—A lecture, entitled "The Orchards of England," will be delivered by Mr. GEORGE GORDON before the Society of Arts, Adam Street, Adelphi, on Wednesday, March 3. The chair will be taken, at 8 P.M., by Mr. W. T. THRELKEL DYER, F.R.S., C.M.G., &c., Director of the Royal Gardens, Kew.

GARDENERS' SOCIETIES AND THE CHARITIES.—We are pleased to hear through Mr. J. LYNE, gardener at Foxbury, Chislehurst, that at a concert held on the 18th inst., under the auspices of the Christchurch Gardeners' Mutual Improvement Association, a sum of £20 or more was obtained for the Gardeners' Orphan Fund.

PUBLICATIONS RECEIVED.—*Guide to Vegetable Culture*, by W. DRUMMOND & SONS, Stirling, N.B., and 158, Dawson Street, Dublin. A small manual, useful to cottagers and allottees.

BOOK NOTICE.

A MANUAL AND DICTIONARY OF THE FLOWERING PLANTS AND FERNS. By J. C. Willis, M.A. Two volumes. (London: C. J. Clay & Sons.)

The following extract from the preface will show the author's object:

"The aim with which I commenced, nearly seven years ago, to prepare this book, was to supply within a reasonable compass, a summary of useful and scientific information about the plants met with in a botanical garden or museum, or in the field. The student, when placed before the bewildering variety of forms in such a collection as that at Kew, does not know where to begin or what to do to acquire information about the plants. The available works of general reference are mostly very bulky and often out of date, and as a rule refer only to systematic or economic botany, and say nothing about morphology or natural history. I have endeavoured to bring together in this book as much information as is required by any but specialists, upon all plants usually met with, and upon all these points—morphology, classification, natural history, economic botany, &c.—which do not require the use of a microscope. . . . The principal part of the book consists of a dictionary, in which the whole of the families and the important genera of flowering plants and Ferns are dealt with. The families are treated very fully, more so than in any ordinary text-book of systematic botany, whereas the genera are treated much more briefly unless they show some feature of special interest that is not common to the family."

We place this extract from the preface in the forefront of our notice, in order to do us injustice to the author, and also because we experience some difficulty in reviewing his production. It is clearly a compilation, and yet its most valuable features are to be found in its originality and novelty of treatment. It is intended, presumably, for the novice, but there is much in it that is only adapted for the advanced student. Again, the two halves of the book, or rather, we should say, the two volumes, seem to be wanting in cohesion. The first and smaller portion is an extremely condensed handbook of general, up-to-date, morphology; the second volume is a *catalogue raisonné* of orders and genera. Altogether, the amount of information crowded into these 600 or more small pages is quite wonderful, and attests not only the assiduity but the accuracy of the compiler. In the beginning the author gives an account of the purposes and general arrangements of botanic gardens, and shows how they may be turned to account by the student. This, strange to say, is a distinctly novel feature in a text-book. After this comes a chapter which will be a hard one for a beginner. It is devoted to the "outlines of general morphology, &c.," and the "probable evolutionary history of the plant," the author adding prudently that we can only speculate with more or less degree of probability upon the course of events, but strangely omitting, or making scant mention of evidence afforded by the embryonic and developmental characters, and by the phenomena of reversion which are so important in this connection. In any case, he leads off with antheridia and spermatozooids, oogonia and ova, zygotes, gametes, sporophytes, sporangia, and other terms which we need not quote, without any attempt at description, and with very little explanation. It is as if a pupil, who had not previously mastered the letters of the alphabet, were set to read sentences and paragraphs, and even chapters. Some very considerable previous knowledge of plant conformation is requisite before the pupil can profit by this very condensed account of morphology in its physiological aspect. It is, for instance, confusing to be told that the sporophyte was "at first undifferentiated and reproductive only." How then did it live!

In dealing with the subject of variation, it is pointed out (as is, indeed, frequently done), that "rudimentary structures are variable." That is a statement, however, which needs some qualification,

for in some groups, at any rate, the systematic botanist looks out for these rudimentary structures to afford him "characters," and places the more stress upon them, for the very reason that they are not acted on by the environment, and are in consequence more constant.

Classification and its principles are clearly treated, and then follows a chapter on geographical distribution as dependent on the environment. Too much stress, however, must not be put on these influences. It is not infrequent in Switzerland to find xerophytes living for a time as aquatics. *Sempervivum arachnoides*, a characteristic "xerophyte," may often be found growing in fissures filled with water.

The fourth chapter is devoted to Economic Botany, a subject dismissed in little more than half a dozen pages. This restricted treatment is, however, compensated for by the information given in the second volume. This second volume is a miniature *Treasury of Botany* brought down to date. For advanced students and experts these little volumes will be most useful for reference, as accuracy of statement and general freedom from accidental errors are as remarkable in them as are the comprehensiveness and condensation of treatment.

THE ROSARY.

PRUNING ROSES

So much has been written upon this important part of Rose-culture, that it is difficult to discover any fresh point of view from which to treat the subject; nor can it be done by briefly pointing out methods of pruning for certain classes, seeing that all but the *Polyanthas*, Scotch, Ayrshires, and Provence, possess varieties, varying as regards habit and strength, or weakness of growth, that no one rule can possibly be given which will meet all cases. What contrasts there are between Margaret Dickson and Etienne Levet, Lady Mary Fitzwilliam and Reine Marie-Henriette, Cleopatra and Rive d'Or, Souvenir de la Malmaison and Mrs. Paul, Blanche Moreau and White Bath, Favier and Mrs. Bosanquet, as examples of their respective classes!

How often in the past, and I fear even with the present day advance in horticultural literature, have we seen yards of valuable growth cut away from our most beautiful climbers! Why should we allow such growth to be made, if only to be cut away at pruning-time? There are not many of our climbing Roses cultivated with the sole object of securing a few blooms of extra quality. They are more generally grown for the artistic beauty of their masses of flower, covering the walls of a house, fence, or arbour, and to get the best results we must leave as much as possible of the new growth intact. With these it is more a question of thinning than of pruning, and we can only remove wood that has got aged and is getting flowerless in consequence. To remove the swaying growths of the previous summer is simply to sacrifice that which would afford the finest show of blossom. Make room for these by thinning, and do not draw them in too closely. These remarks apply more particularly to such rambling varieties as *Félicité-Perpétue*, *Ruga*, the *Banksian*, *Rive d'Or*, *Reine Marie-Henriette*, and *Longworth Rambler*.

The same practice holds good with other extra vigorous growers not used as climbers but as pillar Roses, and for pegging down to the soil, viz., *Paul Neyron*, *Ombre des Rosomanes*, *Boule de Neige* and *Chêne-léon* are splendid pillar Roses, but if the best of the previous season's wood is cut away, the plants are nearly flowerless compared with what might have been the case had the older wood been thinned out, and last year's left almost intact. The 10-feet roots of *Margaret Dickson*, as well as the long upright growths of *Ulrich Bruner*, *Gabrielle Laitz*, *Gloire Lyonnaise*, and others, are by far their most valuable growths. Yet I often see these varieties pruned—nay, not pruned, mutilated—upon the same lines as *A. K. Williams*, *Marie-Banmann*, and varieties with similar habit. What is the result of this? We find a small number of flowers on the plant, and its energies

directed to the production of other lengthy growths similar to those which the pruner has removed. This is the sole reason that so many of our grandest Roses with vigorous habit are condemned as shy bloomers, when the fault really lies with the pruner. By securing the long rods in a horizontal position we get flower throughout their whole length, and at the same time make better space for the development of more such growth coming away from the base of the plant. The long rods which flowered last summer should be cut away in the early autumn, and the young growths secured to stakes, pegging them down again the following spring.

There should be little need of many words as to the pruning of such grand old favourites as *General Jacquemont*, *Alfred Colomb*, and varieties of like habit; but even here we need bear in mind that the weaker the long rods of last season, the harder it needs pruning. *La France*, *Mario Van Houtte*, *Anna Olivier*, *Mrs. Bosanquet*, and *Caroline Testout*, are fair representatives of vigorous growers with bushy habit, and the leads should first be well thinned in the centre, then pruned upon the same basis as the *General Jacquemont* class, but a little more severely. The very weak and erratic Roses like *Comtesse de Nadailac*, *Souvenir d'Elise Vardon*, *Cleopatra*, and *Princess of Wales*, should be pruned with great care. In their cases, I would simply remove pithy and indifferent wood, and slightly shorten back the remainder. I have found these to break stronger from a small eye, so long as well ripened, than from many apparently far more promising eyes, and every piece of healthy growth is valuable here.

I will close with a remark upon *R. rugosa* and hybrid Sweet Briars. If you wish to see the full beauty of these, they must not be pruned, but allowed to grow at will. Nor should they be planted in any position where considerable room cannot be afforded. That old favourite, the *Cabbage*, or *Provence* Rose, needs much closer pruning than might be inferred from its growth. The above is for lovers of Roses, not exhibitors, who prune with that object alone. *A. Piper*.

LILIUM COLUMBIANUM.

This grows over a wide range of country and in many situations. It is found in Oregon from the coast line and the mouth of the Columbia River, throughout the Coast Range, and in the lower portions of the Cascade Mountains. It reaches north-eastern California in *Mo-loe* County, and in the State of Washington is found in the southern part in about the same range as in Oregon. I have no accurate information as to how far it extends on Puget Sound, but it follows the Columbia River valley, and is found in various portions of North-eastern Oregon, and is close to the Idaho line, to my knowledge. It prefers a sandy, well-drained soil, among Ferns, in open woods. It is easily grown in cultivation. *L. columbianum* may be described as a miniature *L. Humboldtii*. The flower has reflexed orange-red segments, finely dotted. The stem is slender, and both it and the leaves are light green. The bulb is compact and ovoid, as in *L. Humboldtii*, but, unlike the latter, the scales are thin. Five hundred average bulbs measure as follows:—100, 4 to 5½ inches in circumference, three-quarters of an ounce each; 348, 3 to 3½ inches in circumference, one-third of an ounce; 54, 2½ inches in circumference, one-fifth of an ounce. *L. columbianum* grows from 1½ to 4 feet in height, and usually flowers the first year. I find sandy alluvium best answers its needs.

The bulbs of *Lilium Bolanderi* are almost identical with those of *L. columbianum*. I have not flowered *L. Bolanderi*, nor have I seen it in flower. It is described as being from 6 inches to 3 feet high, and few-flowered. The leaves are whorled, and the general habit seems to be similar to that of *L. columbianum*; the flowers are, however, quite different, the segments are not reflexed, and the flower would seem to be broadly trumpet or bell-shaped and nodding. A collector who saw it in full flower this year describes it as a very handsome flower of a

pleasing red, and growing in a high mountainous region in a soil of rocky debris and leaf-mould. Habitat indefinite, Humboldt and Del Norte Counties in North-western California.

In this group will fall a fourth species of the fern north, related to *Liliium columbianum*, and as yet unnamed. In this species the habit of *L. columbianum* in bulb and leaf is combined with a peculiar-shaped flower. The lower half of the segments forms a closely-constricted tube, from which the upper portion spreads horizontally in a rotate flower, finely dotted with maroon. This species is nearly as fragrant as *L. Parryi*, *Carl Parry, Ukiah, Calif.*, in "*Garden and Forest*."

A GERMINATING APPARATUS.

Those who have at any time been engaged in cultivating Ferns from spores, know by experience how great a number of cultures perish. Germs and spores of animals and plants, of insects, worms

parts, which can be opened independently of each other, if for some reason or other should make it necessary to open the lower part only.

The pots, covered with round glass plates, are placed in zinc tubs filled with sand and water. These zinc tubs are arranged on small wooden trestles, under which are found the heating-tubes, that may consist of ordinary water-pipes.

These tubes are provided with taps (1, 2, 3 and 4), by means of which, in case the temperature should become too high, the action of some of the heating-tubes can be suspended.

One of these tubes there is a tap, indicated by a small circle, which enables us to allow the air present in the water to escape. The direction in which the water flows is indicated by arrows.

The water is heated in a copper, w, in which there is a thermometer contained in a tube to prevent the quicksilver, in case the thermometer should burst, from getting into the water, and the water from escaping from the tubes.

spores, it can be protected against all sorts of damaging influences. As said before the hot-houses of the Botanical Gardens are mostly very favourable to the development of lower organisms, and formerly I could keep the cultures clean only with unremitting vigilance and the utmost care, and they were sure to be destroyed if I were prevented from watching over them personally. In the germinating apparatus, on the contrary, whatever is sown comes forth and thrives; and, as regards keeping clean, hardly require any care at all, provided the spores have been carefully selected, and previous to sowing the spores, the peat and the pots have been carefully boiled, so as to be freed from all possible animal and vegetable germs and spores. *Utrecht.*

NURSERY NOTES.

MESSRS. F. SANDER & CO., ST. ALBANS.

THE plant-houses here always present a fresh and bright appearance, and a constant changing display of flowers which the large and varied stock necessarily assures. The interesting character of the groups observed in the rockwork terminations to the houses, and about the pools of water with which many of them are furnished, has been increased of late years by the presence of new or rare foliage plants, which it may be remarked, have for some time past taken an almost equal place in the St. Albans houses with the Orchids. Where Orchids and foliage plants are arranged together, pretty effects are produced. In several of these rockery displays the new *Dracaena Godseffiana*, with its elegant sprays of bright green leaves, spotted with yellow, and which at this season are also furnished with heads of white fragrant flowers, is a conspicuous feature. It seems the best of plants for growing with and among Orchids, for table decoration, or as cut sprays. Indeed, there seems to be few purposes to which it cannot be put. In one of these arrangements a handsome lot of *Cattleya Trianae*, among which were a fine form, superior to C. T. Backhouseana, and several very good C. T. alba, together with good plants of the white *Cymbidium eburneum*, some *C. giganteum*, C. Lowianum, &c., form the floral part. The display of *Cattleya Trianae* also extending down one side of the house, while on the other side the first flower of C. Gaskelliana, which follows C. Trianae, was open.

In another group, the white and green-leaved *Dracaena Sanderiana*, now a favourite decorative variety, was the principal foliage-plant, and overhead hung a fine lot of *Nepenthes*, the prettiest of which was *N. Sanderiana*, with pitchers as large as those of *N. Rafflesiana*, the wings and lid beautifully tinted and veined with bright rose colour.

Passing along the lofty range which forms the connection with the ends of the various houses that run at right angles to it, we found a good show of *Dendrobium crassinode*, *D. Wardianum*, varieties of *D. nobile*, and other *Dendrobies*, with here and there groups of *Celoglyne cristata*, and of the variable forms of *Cypripedium insigne montanum*, which has been so prolific in good things. Glancing at the groups in the houses passed, in one arranged around two gigantic plants of *Arachnatum* (*Vanda*) *Lowii*, were some specimens of the white-flowered *Cymbidium Mastersii*, some fine forms of *Cattleya Trianae*, and many showy spikes of *Oncidium splendens*, *Laelia tenebrosa*, *Laelia purpurata* in sheath, *L. crispata*, and other Brazilian Orchids occupying the house beyond.

In another house the flower-spikes of the new hybrid *Eucharis - Elmaetha*, and *E. Stevensii* were appearing profusely above the leaves; and associated with them good examples of white and coloured *Laelia* accurs in flower. Another group consisted of plants of *Lycaste Skinneri*, among which were several fine examples of the large or best form of *L. S. alba*, also *Vanda Kimballiana*, *V. Amesiana*, *Laelia harpephylla*, *L. cinnabarina*, *Platybasis glumacea*, some species of *Cattleyas*, and many *Sobralias*, some of which had the buds prominent.

Among an interesting batch of botanical Orchids

FIG. 11.—GERMINATING APPARATUS.

Fig. 1.—a, admission of the gas; m, manometer; p, pressure-regulator; b, burner; w, heating-copper; o, place where the hot water is admitted, vertical section; h, place where the hot-water escapes, vertical section; r, reservoir for the overflowing water; z, flask of Mariotte.

Fig. 2.—a' and b', the same places in horizontal section, as a and b, in vertical; 1, 2, 3, and 4, taps; when we work with six pipes, 1 and 2 are open, 3 and 4 closed; in order to work with four pipes and suspend the operation of the second and third pipes, 1 is closed, and 4 opened; in order to work with two pipes and suspend the operation of the second, third, fourth, and fifth pipes, 1 and 2 are closed, 3 and 4 opened. The circle in the first pipe indicates the tap, through which the air present in the water can escape. The copper casings used for the apparatus should be screwed together to prevent danger of a fire.

algae, fungi, and musci, often spring up in great numbers, killing in a very short time the healthiest cultures.

As the hot-houses of the Botanical Gardens, where such experiments are made, mostly offer the most favourable conditions for the development of lower organisms, the cultures are always in danger, unless they can be closely and regularly watched. To avoid these dangers, I have caused a germinating apparatus to be constructed, as shown above (fig 11). The illustration is at about one-fifth of the real size. At first it did not work with the accuracy which might reasonably be expected, but after some experiments, the apparatus assumed the form represented by the illustration, and since that time it has been a great success.

The germinating-apparatus is, if possible, placed in the window-frame of the study, one looking south. The top and the side turned to the street are provided with double panes; the side facing the study has three glass-doors, of which the middle one consists of two

The water is heated by a gas-burner, b. The copper is contained in a zinc box, and is connected by means of a vertical tube with the reservoir, o, which is covered with a lid to keep the dust out, and prevent evaporation. When in this tube the water falls to the lowest level, water is admitted into it from the flask of Mariotte, f.

The gas is supplied through the pipe, m; on the left is a manometer, m, to measure the gas-pressure; on the right side is seen a pressure-regulator, a double governor, r. At first I used a Bunsen mercury-regulator; but since by accident it burst, causing the gas-flame to go out, I have made use of the double-governor.

The supply of gas, as required by the temperature of the surroundings, can, of course, be regulated by means of the tap, t, admitting the gas.

A great advantage of the germinating apparatus is that it is placed in a room directly under the experimentalist's personal supervision; and that, when used exclusively for germinating experiments with Fern-

were noted in flower the rare *Oncidium Brunescens*, *Miltouia Endressii*, *Prescottia plantaginea*, *Leptotes nana*, *Epidendrum polyanthum*, *E. tridactylum*, *Eulophia virens*, *Cataseum discolor*, *Cymbidium Devonianum*, *Cypripedium Schomburgkianum*, *Trichopilia sanguinolenta*, some singular *Agavecum* of small growth from Madagascar; *Pleurothallis stelis*, *Masdevallia*, &c.

In the cool-houses, the display consisted of a number of varieties of the true *Odontoglossum nívium*, *O. Andersonianum*, some very fine *O. lateopurpureum*, of which one form of the *hystrix* section was the most beautiful and very large flower; *O. Rossi majus*, *O. Harryanum*, *O. Pescatorei*, *O. crispum*, *O. triumphans*, *O. Edwardii*, some good *O. Halli*, both the yellow and the white-tipped forms; the rare *O. nevadense*, *O. Sanderianum*, *O. Hunnevellianum*, and some remarkable hybrids. Also of the cool-house *Oncidium*, *O. superbiens*, *O. cucullatum*, *O. serratum*, *O. Lucasianum*, &c. In the houses containing hybrid *Orchids*, a good show was made of varieties of *Dendrobium* × *Ainsworthii* D. × *Dalea*, *D. Cassiope*, *D. × Owenianum*, the rarer varieties of *D. noble*, such as *D. n. Bullianum*, *D. n. Sanderianum*, *D. n. nobiliss.*, &c.

In another house plants of *Phaius tuberculatus*, and a batch of *P. × Marthin*, and a plant of the new yellow *P. × Ashworthianus*; some *Pescatoreas* and *Bolles*, and scarlet *Anthuriums* were observed in flower.

One side of a warm-house was occupied by a large importation of *Phloxopsis Stuartiana* and other species, some of them being in flower; and in the houses devoted to *Cypripedium* a good display was made of hybrids and species, among which *C. Chamberlainianum* and the allied *C. Victoria Marie*, many varieties of *C. villosum* and *C. insigne*, a large number of the handsome *C. × Calypso*, *C. × Lathamianum*, and many other hybrids, were noted. Other important batches observed consisted of *Vanda cœrulea*, the pretty *Steuoglossis longifolia*, from Natal; and the free-flowering, violet-coloured *Utricularia Forgetiana*; some good pieces of *Epidendrum Wallisii*, a number of plants of the pretty white-flowering *Deutzia Lemoinei*, plants of *Renanthera Insechootiana*, well recovered from their journey; and some of the fragrant *Agavecum Chailleanum* in flower. Among *Begonias*, the pretty *B. Gloire de Lorraine* seems to be perpetually in flower.

HOME CORRESPONDENCE.

THE RAINY DAY! (GARDENERS' ROYAL BENEVOLENT INSTITUTION).—Dr. Watts told us all about the "busy bee," and Franklin ("Old Moore") long ago advised our "making hay while the sun shines," as a provision against "a rainy day;" and I should like to add my own convictions respecting the necessity that now exists for, at least, all well-to-do gardeners to subscribe to the Gardeners' Royal Benevolent Institution. If there is any one marked feature in our moral or ethical progress during the past sixty years, it certainly consists, in a great measure, in the growth and development of altruism, or unselfishness. In some cases, indeed, it may, and has been thought, that the upper classes have been legally nudged in favour of the working masses; but even if we confine ourselves to "voluntary contributions" we shall find that benevolence and unselfishness are, so to speak, "in the air." Say or do what we will, life's noblest goal is self-denial and self-sacrifice. In no way does this appeal to most of us so strongly as in the case of our oldest gardening charity, and the practical interest in it may be best shown by all gardeners giving at least something to its aid, either in pecuniary contributions, or by acting as voluntary agents in recommending the Society to others, perhaps better able to contribute than they are themselves. In the special case of the Gardeners' Royal Benevolent Institution we have a society founded in 1838, and of which Her Majesty the Queen is patroness. The Society was established with the laudable object of relieving, by means of pensions and otherwise, aged and infirm gardeners, market gardeners, market growers, nurserymen, seedsmen, their widows, and others engaged in horticultural pursuits, and its work has been well done. The pensions were

originally £16 per annum to men, and £12 per annum to their widows, but the amounts were increased in 1885 to £20 and £16 respectively. During the time it has been in existence the Institution has distributed in pensions and gratuities £71,000. It inculcates the principle of "self-help," by giving a preference to those candidates for assistance who have contributed to its funds. Persons of sixty years of age and upwards, if incapacitated from work, and if they comply with the rules, or younger in case of total disability, are eligible for pensions. One hundred and sixty persons are now receiving permanent aid, whilst there are twenty-nine pressing cases on the list awaiting election. Additional funds are therefore much needed to meet some of these urgent claims. An annual subscriber has one vote for each guinea. A donation, or collection, of ten guineas constitutes life-membership, with one vote at each election. A life-subscriber has one vote for life for ten guineas, and an additional vote for life for every additional ten guineas. A large proportion of the total funds of the Society has been derived from the voluntary contributions of those amateurs who employ gardeners, and nurserymen and others have in many cases given most liberally to its funds. The Society is ably and economically conducted on the soundest and best business principles, and what is now most needed is the help and personal interest of a larger number of practical gardeners. It is, indeed, depressing to find how small a proportion of those for whose benefit it is worked really contribute to its funds, or take any hearty interest in it whatever. No other institution or society known to me guarantees a pension for life after sixty years of age to total incapacity to any gardener who makes a single payment of ten guineas, or who subscribes fifteen guineas in fifteen annual payments. Seeing how generous the patrons of gardening have been, and still are, it now behoves all self-respecting gardeners to put a hand to the wheel, and to do at least something themselves for such an excellent institution. Much can be done either by contributions direct, or by their saying a word in due season to their employers and friends. Now and then private gardens, with particular specialties, may be opened to the public at a nominal entrance fee, and the proceeds given to the fund; or gardeners may often be able to give some entertainments to the same end. One of my friends is most generous in sharing surplus plants, seeds, and cuttings with visitors, but only on the condition that they give at least something to his collecting-box shaped like a watering-can, while others use the collecting-cards whenever opportunity occurs. Another kind friend, who is hospitably inclined and fond of cards, plays penny points with his guests on the sole condition that all moneys so used shall go into the collecting box for his favourite charity. As a matter of fact, however, "wherever there's a will there's a way," and even the poorest gardener with a family may do something, however little, towards an institution that never fails its supporters. As a proof of the kind thought and consideration of those at the head of the Institution, we may draw attention to "the Victoria Era Fund" recently inaugurated to give a sum of money to all who are unfortunate and unsuccessful at the annual election of pensioners. The idea is a noble one, viz., that even the disappointed shall be solaced, and that "none shall be sent empty away." A sum of £5000 is urgently required as a principal fund and others to be paid to give or collect for this sum. Are there not 7000 gardeners in England to-day able to give £1 each towards this end? I feel sure there are, if only they would interest themselves and their friends in the matter. Horticultural Societies, and Gardeners' Mutual Improvement Societies, might do much by the use of collecting-boxes and cards at their flower shows or meetings. Not only head gardeners, but foremen, and young gardeners, especially those for whom lodgings and other advantages are provided, might do something, however small, for, as our Scotch friends say, "nary a mickle mak's a muckle." In a garden with twenty men a penny per week from each would yield £1 6s. 8d. a year, and if this were paid into the Post Office Savings Bank every week the money would be safe, and increased slightly by interest to boot; while the whole transaction would afford an object-lesson on thrift and business principles to all the young men concerned. In some cases gardeners who have subscribed £10 to £20, have been elected as annuitants, and have received ten or twenty-five per cent. of the principal they had originally invested; and I believe there is no instance of a subscriber not having been elected after due application has been made.

Unfortunately, it is not possible for every gardener to subscribe largely, but there are few who could not afford, say, 5*d.* a week, so as to make up a guinea a year. It is a trifle like this—but by carefully at stated intervals that will provide a sure and certain hope for a decrepit old age. As an old subscriber of £15 15s. once said to me, "The wife or myself is sure of something at least if we fail, and that thought alone is a great consolation, and worth the money we invested many times over." He, good honest man, has never earned more than a pound a week, with his cottage and garden, and he has had a family of five to start in life; but all are doing well, and at nearly seventy years of age he is hale and hearty, and respected by his employers; and although he is eligible in some ways, I never expect to see him an annuitant of our good old institution. *F. W. Burbidge.*

THE CLASSIFICATION OF APPLES.—In inviting the Council of the Royal Horticultural Society to undertake the task of formulating authorised lists of Apples which shall be termed respectively cooking and dessert, and so regarded throughout the kingdom, the requisitionists do not seem to have fully realised the exceeding difficulty of the undertaking. No such classification could be complete that did not include every Apple of any importance, of which, as the celebrated Chiswick Congress show that there are some 1500; but it would still be difficult to classify all unknown local Apples—evidently an impossibility. But even attempting the work partially, dealing solely with such varieties as are commonly listed, it would be found that were a dozen of the leading fruit catalogues of the kingdom examined, that some 400 assumed diverse varieties were published. What would still further tend to difficulty in the matter, is the undoubted fact that traders differ so largely amongst themselves as to the proper classification of varieties that confusion is excessive. No doubt, it will be pleaded that were some fitting authority to classify these varieties, traders would follow that lead. If they did so, it would indicate great humbleness on their parts, as it would tacitly admit that through all the years past they had been in the wrong. Yet there can be no doubt but that so long as the arbitrary distinctions of cooking and dessert, or table and kitchen sections, are to be maintained, the more probable is acceptance of my classification, however partial. It is worthy of note that the present botanist (and we may say agriculturist) has grown out of the action of the York Glais Committee in inserting into the conditions for a miscellaneous collection of fruit, the arbitrary term "dessert." A mixed or miscellaneous collection of fruit is invariably inclusive of several kinds, and often of diverse varieties. It also invariably comprises fruit that is ripe, or nearly so. The Royal Horticultural Society, in its Crystal Palace schedule, is content to ask for ripe fruit, which, seeing that these fruits are for table use, seems to meet every requirement. The National Chrysanthemum Society, at their Jubilee show, were equally less exacting, getting all that was possible by asking for a collection of nine dishes of fruit, thus using an arbitrary term. Had not the term dessert, which is a foolish one to employ, been in the York schedule, Mr. Riddell would never have been disqualified, and the subsequent bother would not have occurred. However, the Royal Horticultural Society had no desire to shirk the task sought to be imposed upon it, but preferred to proceed in its own way, which is: "We cannot undertake to formulate lists of Apples classified to suit every one; but as we hold the greatest Apple show in the kingdom at the Crystal Palace, and have classes for Apples in sections, we will, through the agency of a small committee of experts, arrange lists for our own show-schedule of what shall be by that body properly regarded as eating, cooking, or compound sections, which, so far as the Crystal Palace show is concerned, will be regarded as authoritative, and we leave to the country at large to accept our classification or leave it. These are not their words, but they describe practically what has been attempted. The committee seems to favour the term "eating" to the other one, "dessert," but allow "cooking" to remain. Lists of about seventy of the best known and most commonly grown and shown varieties of eating and of cooking Apples have been compiled, and from these will be either starred or withdrawn and put into a third list certain few varieties which cannot be rigidly classified as either absolutely, but may be well regarded as compound or suitable for both uses. But even these have first been put into the sections to which they seem primarily to belong. Of course when these lists are completed, they will be published in the

Crystal Palace Fruit Show Schedule, and these will until further revised show authoritative under the Royal Horticultural Society. There can be no doubt that classification is a matter of exceeding difficulty, for a variety that may be only fit to cook in one part of the kingdom is delicious eating in another. Then tastes vary very much, and whilst some will have high favour, only such as Cox's or Ribston give others prefer the soft flesh of Pomona or of Elmhurst Orange Pippin; whilst others even have fondness for the keen acidity of Golden Noble, or Wellington, and certainly the latter four do furnish for the table most beautiful samples. All have particular goodness for softness of flesh, without acidity, and but little sugar. Youth often has preference for sharpness, whilst others prefer sugariness. Then there are numerous small and rather hard varieties included in the eating section, that have fancy names, but are really worthless either to grow or to eat. Many very fine handsome rich-coloured, soft-fleshed, and exceedingly pleasant Apples, on the other hand, are classed amongst cookers, because they are large. It is difficult to correct all this apparent misplacement, but no doubt what the Royal Horticultural Society is doing will greatly help to that end. *Pomona*.

TO CLEAR MEALY-BUG FROM GRAPE-VINES.—The Vines at the place where I am now gardening were greatly infested with mealy-bug when I entered on my service three years ago last November, none of the bunches of Grapes being fit to eat unless they were washed in clear water, which, of course, spoiled their appearance. When the crop was cleared off, the Vines were then scraped almost bare of bark, pruned, and the surface-soil of the border taken away to a depth of several inches, and the Vines washed with water containing 2 oz. of soft-soap to the gallon, and used as hot as could bear the hand in it. This being done, the Vines were dressed with a mixture consisting of 1 lb. of soft-soap, 1 lb. of flowers of sulphur, about 3 lb. of clay, a handful of soot to the gallon of water, which made a kind of paint, to which I added half-pint of gas-tar to every ten and a half pints of the mixture, well mixing all together. This paint was used on the canes from below the ground-level to the top, filling up all crevices with it, but not much was used about the buds. I watched the Vines closely for any appearance of bug, and only discovered a few, which I touched with a camel's-hair pencil dipped into a mixture of one-quarter pint of water, two tea-spoonfuls of paraffin, and a piece of soft-soap of the size of a cob-nut, the soap and paraffin being first mixed, and the water added gradually. The mixture should be well stirred when it is used, and should be kept in a corked bottle in the vinery. Since carrying out the above sort of treatment, there are now but few bugs on the Vines. *D. J. H.*

NAILING PEACH TREES.—I have been interested in the notes appearing under the above heading, and would like to put in a plea, viz., for a nailed Peach tree, much as I am in favour of wire. All the same, a good nailer will finish a tree nearly as quickly as another can tie one, and when it is finished the nailed tree will look better than the tied one. The following are a few of the advantages of nailing:—In the first place, it does not matter how closely the wires are placed, there will always be some cross supports required to which to secure the ends of the shoots that will not touch the wires, and this causes the workman to have recourse to matting, string, or sticks, which take time to arrange. Whereas with the nails you can do exactly what is required without loss of time; and with shreds, by using these long or short, pressure that often results in gumming is averted. I have an idea that gumming is from one cause and another more prevalent in tied than in nailed trees. Peach trees should be untied or unnailed every year, and unless this is done one cannot have well-developed trees in good condition for any length of time; as all trees grow under the principle (extension) have necessarily to be rearranged every year. I think it may be taken for granted that there are in the country quite as many trees that are nailed as are tied to wires; in fact, in many of the best gardens wire is not used. I have noticed that better and finer crops of fruit come from nailed trees, and considering all things, I think I intend to stick to it, and to trees on outside walls. I have not found that fruit trees suffer in any way from being close to the wall, and never failed to secure good crops, 1895 and 1896 being exceptions, owing to the drought and heat. I have taken forty

dozen fruits from one five-year-old tree. The following varieties are growing here on the south wall, and these without exception do well: Waterloo, Ansdun June, Early Grasse Mignonne, Dymond, Barrington, Goshawk, Royal George, Sea Eagle, with Lord Napier and Victoria Nectarines, and sundry seedling Peaches and Nectarines. The secret of successful Peach culture does not consist in the way a tree is fastened to the wall, but in affording trees a good start in suitable soil, proper drainage, keeping them free from insect pests of all kinds, and severe pruning so that the crowding of shoots is avoided. The border must be well supplied with water, and the syringe or engine used freely in warm bright weather. The Peaches and Nectarines whose names I have given afford fruits from the end of June to the end of October, after which date Peaches are no longer fit for dessert. *H. N. Cook, Compton Bassot, Calne Wilts.*

SEED PODS ON POINSETTIA PULCHERRIMA.—Here we have two plants which have produced seed-pods on them, the only two out of a batch of 150 plants. It is not a rare occurrence where a large batch of plants are grown. I had one or two which some three years ago, and grew the seedlings, but there does not appear to be any difference in them when in bud than those grown from cuttings, they only grow taller and are paler in colour. I have enclosed a bract with a seed-pod upon it, for your correspondent. *A. S. Cole.*

— In reply to "X," in a recent issue, it may be stated that this plant produces seed very freely if fertilised. The seeds vegetate readily when quite matured, if sown in heat. I was successful in raising plants from seeds six years ago, but they were not so good as the ones which I crossed them with *Euphorbia jacquiflora*. *H. J. Smythe, Basing Park Gardens, Alton.*

THE VICTORIAN ERA FUND.—Mr. Harris, in the *Gardeners' Chronicle*, p. 129, writing on the above subject, suggests that gardeners, foremen, journey-men, &c., should subscribe a fixed sum this year towards the Gardeners' Benevolent Institution, &c.; also that gardeners should be asked to collect from men employed under them. Although the sum he mentions is small, I do not consider that gardeners should ask the men to subscribe; their pay is usually so small that they can ill afford even so small a sum as he mentions. But I would like to suggest that every head-gardener should be induced to become an annual subscriber; and if such a rule were followed throughout the kingdom, we should not then require any collection or extra funds. *A Life Member and Annual Subscriber.*

THE CEDARS OF LEBANON.—In an interesting article from the pen of J. Paseo Oliver, Capt. Royal Artillery, which appeared in the issues of the *Gardeners' Chronicle* for August 9 and 16, 1879, an account of journeys in Palestine, the Northern Lebanon range, and El Bekka is given. The article was illustrated by a sketch by Captain Oliver of the Lebanon Cedars as they then existed. The trees, large and small, numbered 285 specimens, the smallest being from 50 to 80 years old. No young trees were springing up, although there were cones in abundance, and germinating seeds were observed far beyond the actual area covered by the trees. If it were not for the goats which eat off the seedlings, and the visitors who tread them under foot, a few decades would see a large extension of the area under Cedars, and eventually the formation of a large wood. Perhaps some reader of this note may be able to inform me if anything has been done since 1879 to carry out the idea of protecting this grove, which is the property of the Patriarch of the Maronites, who, at that time, resided by the Dog River, not far from Beyrout. Some articles have appeared in the *Gardeners' Chronicle* recently which would seem to indicate that the Cedar of Lebanon shows seminal variation. Perhaps persons who have closely observed these trees in their native habitat would be enabled to say if this inference has any foundation in fact. *A Traveller.*

CYPRIPEDIUM INSIGNE SANDERÆ.—I am pleased to see how you got your correspondent, "S. S." to facts (see *Gardeners' Chronicle*, p. 128). The plant shown at Manchester was not any portion of the Pickering Lodge plant. I see he writes that Mr. Ball has got very much mixed; but I should like to have his opinion of his judgment when

he states the flower shown at Manchester is not the true *C. i.* Sanderæ, and much inferior to Mr. Ball's flower, when I inform him that it came straight from Baron Schroder's. *Fred. Hardy.*

VIOLET PRINCESS OF WALES.—Having seen some remarks in the gardening press attributing shyness in flowering to this new Violet, I would like to say that such has not been our experience. It has given us good flowers and foliage all the winter. Growing side by side with most other varieties, it has proved superior to all of them, including *The California*. It is, moreover, remarkably free from damping during the winter months. Enclosed is a bunch of blooms for your inspection. *G. Morphett, Hulsewood Gardens, Darford Heath.* [Very fine flowers indeed. *Ed.*]

SOCIETIES.

ROYAL GARDENERS' ORPHAN FUND. The Annual Meeting.

FEBRUARY 19.—On the above date was held the annual meeting of those interested in the Royal Gardeners' Orphan Fund. The meeting took place at 4 P. M., at Anderson's Hotel, Fleet Street, London, E.C., and the poor attendance may be partially explained by the wretched character of the weather during the day. Among the score or so gentlemen present were the following: Messrs. W. Marshall (Chairman of Executive Committee), B. Wynne, R. Dean, J. Hudson, Jas. Walker, F. A. Assheer, A. W. G. Weeks, Jas. Melody, G. W. Cummins, H. J. Jones, Geo. Reynolds, W. Rowan, J. W. Lyell, H. Jones, W. Compell, A. F. Bar (Secretary), and representatives of the Horticultural Press. After the reading of the minutes of the last meeting, which were approved, it was proposed by Mr. MARSHALL, Chairman, that the report presented by the executive committee be adopted. It ran as follows:—

REPORT AND STATEMENT OF ACCOUNTS FOR THE YEAR ENDING DECEMBER 31, 1896.

In presenting their Ninth Annual Report, the executive committee can heartily congratulate the subscribers on another year's operations—generally satisfactory and encouraging.

If the financial support given to the Fund as annual subscriptions be not as large as the committee could desire, yet from other sources it is evenly maintained and the interest in the progress of the Fund widely felt. The Fund was instituted in 1875 in commemoration of the Jubilee of Her Majesty the Queen.

The year 1897 finds your committee assisting in connection the longest reign of a British Sovereign, and in consideration of this auspicious event, they recommend to the subscribers that the whole of the candidates be elected by resolution of the annual meeting.

To those who have so generously, and in not a few cases so constantly supported the Fund by means of special donations, the committee owe a great debt of gratitude. By sums derived from money-boxes, concerts, the opening to the public inspection of gardens and plant-houses, especially during the season of the Chrysanthemum, the sale of flowers, &c., considerable additions have been made to the Fund.

The Annual Festival Dinner presided over by His Grace the Duke of Bedford, the president of the Fund, proved a most gratifying success, resulting in a considerable augmentation to the charity; and the committee tender to His Grace their most grateful thanks for his able advocacy of the claims of the institution, and also for his generous contribution. Among other contributions to the Festival Fund was that of the tenants of, and the growers of, the Covent Garden Market, who subscribed the sum of £34 12s. 6d., a measure of support highly appreciated by the committee; and they also desire to gratefully acknowledge the great assistance rendered by Mr. J. ASSHEER in obtaining this welcome gift.

The number of children who have been placed on the Fund since the commencement is eighty-five; of this number fifty-eight are now receiving the benefits of the Fund, to be increased by those recommended for election this day. The number of children who through the age limit and other causes have ceased to be chargeable to the Fund is twenty-seven.

One most pleasing cause of gratification to the committee is the letters of deep and earnest thankfulness received from the mothers of children who have ceased to be chargeable to the fund, acknowledging the great help the quarterly payments have proved to them in times of necessity. The committee, by means of the special grants they are empowered to make, have also been enabled to render timely assistance in starting several orphan in life.

The total amount paid to the children since the commencement of the Fund is £1,815.

The members of the Executive Committee, who retire by rotation according to Rule IV, are MESSRS. MARSHALL, BATES DEAN, HERRIS, JONES, MAY, REYNOLDS, and WYLLIE, all of whom being eligible offered themselves for re-election.

The best thanks of this committee are due, and are hereby tendered to the Treasurer, T. B. HOSWORTH, Esq., and the Auditor, JOHN FRANK, Esq., who retire after holding office

since the establishment of the Fund. The committee have great pleasure in announcing that N. N. SHERWOOD, Esq. (a magnificent supporter of the Fund), has kindly consented to accept the office of Treasurer, and PETER BARR, Esq., that of Auditor, and they are hereby nominated by the committee.

Mr. A. F. BARRON is again nominated as Secretary at the same remuneration.

CASH STATEMENT FOR THE YEAR ENDING DECEMBER 31, 1896.

Table with columns: Receipts, £ s. d., and Expenditure, £ s. d. Includes items like Balance from last account, Subscriptions, Donations, and Investments.

Table with columns: By Allowances to Orphans, £ s. d., and Balance, £ s. d. Includes items like Emma Sherwood Memorial, Annual dinner, Secretary's salary, and Cash at banks.

Having inspected the securities and examined the books and vouchers supplied to us, we hereby certify the above account to be correct. (Signed) M. ROWAN, Chairman

Dated January 23, 1897.

Mr. MARSHALL, in a brief commentary upon the report, drew the attention of the meeting to several letters that had been received from the guardians of children the committee had helped from the Fund, all of which were satisfactory, as showing the extremely useful purpose served by the grants of money, and the appreciation evident on the part of those responsible for the children's welfare.

The next business was that of proposing votes of thanks to retiring officers, and the election of new ones. Mr. T. B. Haywood, who has been treasurer to the Fund since its inception, retires with the thanks of all, and it is satisfactory to know that the office will be taken up so worthily a gentleman as Mr. N. S. Sherwood, who was proposed by Mr. R. Deu, seconded by Mr. J. W. Bates, and elected with enthusiasm.

The CHAIRMAN then rose to propose that, there being thirteen applicants for benefit from the Fund, the whole of them be elected. He said that it was most satisfactory that the Society, which, it would be remembered, was inaugurated in 1887, to celebrate the jubilee of Her Majesty's reign, had disbursed a sum of nearly £5,000 to children, and at the same time had managed to put away another sum

approaching £10,000. The committee thought that under such circumstances (and it being Her Majesty's Diamond Jubilee year) it was warranted in recommending the election of certain members of the committee. This was approved by the meeting, and it was next resolved, upon a proposition by Mr. Asshe, that a copy of the previous resolution be sent to Her Majesty the Queen, and to the Patronesses of the Society the Princess of Wales. A hearty vote of thanks to the Chairman concluded the meeting.

A friendly dinner of the members of the committee and subscribers to the fund afterwards took place at the same hotel, Mr. Owen Thomas presiding. (See p. 110)

GHEENT HORTICULTURAL

FEBRUARY 7.—The Chambre Syndicale des Horticulteurs Juges held their last monthly meeting on the above date, when the following awards were made:—

Certificates of Merit to M. Jules Hye (par acclamation) for Cyripedium insigne Sandere; Baron Schroder, and for Fadio-Cattleya Pallas (C. Louviana x L. crispata); to M. Ed. Pynaert van Geert, for Pteris Boultonii; to Messrs. Linden & Co. (de Valenciennes), for Cattleya Trianae imperator; to M. Jules Hye, for Lycaeus Polakii (par capill); to the same exhibitor, for L. (L. insigne), and M. A. Mance, ally, and for (Chontoblossum Uro-Schmieri); to M. Capitaine, for Clivia M. Capitaine; to M. Jules Hye (par acclamation et vote felicitations du jury), for a set of seedling Cyripediums; to M. Capitaine, for Clivia Mille, Aline Capitaine; to M. Jules Hye, for Dendrobium eximium, Vriesea Montium (D. psittacinum, Dendrobium noble, D. noble nodulosum, and for Vriehidium ochraceum giganteum. An award was also made (par acclamation et vote felicitations du jury), to Messrs. Hugh Low & Sons, of London, for Cyclamen "Bush Hill Palace."

Certificates for cultivation and blooming were allotted for "Dendrobium biflorum, from M. L. De Smet-Duvrier; Cyripedium Chamberlainianum, from M. J. de Cock; Miltonopsis Bleanum, from M. Jules Hye; Vriesea punctulata, from M. Podaeman-Maenhout, and for Dendrobium nobile Cookson, from M. Jules Hye.

Certificates for seedling cultivation were awarded to—M. A. Rigouts (de Valenciennes), for Niphariium striatum; M. Em. de Cock, for Aralia elegantissima; M. Ed. Pynaert van Geert, for Cyripedium Lathamianum invarium (villosum x Spicerianum); M. A. Rigouts, for Dielenfilia Fominieri, Tillandsia foeniculata, and T. tessellata; to M. Em. de Cock, for Epidendrum minutiflorum, and M. M. De Smet-Duvrier (par acclamation), for Croton Hamburgianum.

Honorable mention was accorded to—Kentia Belmoreana, from M. E. L. Pynaert, Vriesea Montium (D. psittacinum x Enchlidium Jonghii), 1896, from M. Podaeman-Maenhout; Aralia Chabrier from M. Bernard Spica; Calamus subcaudatus, from M. Ed. Pynaert; Tillandsia Lindenii from M. Podaeman-Maenhout; and Dracena intermedia (D. cammifolia x D. linearis), from M. A. Rigouts.

The jury have to see at the next meeting Cyripedium Josephine d'Albais (Harrisianum x Chantini, shown by M. Ed. Pynaert Van Geert.

MANCHESTER ROYAL BOTANIC.

The arrangements for the year 1897 show no lack of energy on the part of the Council, notwithstanding the dispiriting decrease of public support at the shows of the season.

The first show, which generally consists mostly of Orchids, will take place on March 16 and 17 in the Town Hall. The second and great Whitstable show, which has hitherto been eclipsed by the Royal Horticultural Society's display at the Temple, is due to take place on the 25th and 26th inst. The third show is the Rose Show, to which a Cottagers' Exhibition is to be added. Then there will be the Chrysanthemum Exhibition, and an effort will be made to obtain a great success, and as large money prizes are to be offered, they will probably be a popular response. Altogether on hopes for a return of prosperity to the Society, and under the management of Mr. P. Weather's and an active Council little is likely to be wanting to place its finances on a satisfactory basis, and to obtain the pride of place which all Botanic Institutions ought to hold in great centres of commercial activity.

The plant-houses contain species interesting to a young botanist, as well as others that please the public who lose the glare of display merely. The half-hurly Rhododendrons in variety, combine sweetness of perfume with delicate coloring, and are very appropriate to the masses of the hardy Rhodo-kadon species are lovely, the indoor culture softening the colours into a captivating shade of lilac. The Camellias are splendid plants for a show house. We were glad to see among the whites, and pinks, and varicoloured double flowers, the high-colored C. reticulata, and its associates. It is a most beautiful flower, and particularly Chandleri elegant, of the soft pink of Saccu's nova, but its flowers being single, and covering a larger surface, are more telling. These associated well with the Palms and Tree-ferns in the lofty house. Clivia (mont-phyllon) minimum is a splendid "straggler" in the flower, well adapted for a similar instance to that once reported in the Gardeners' Chronicle from the Edinburgh Botanic Gardens, where it was flowering en masse under the shade of Sanfernius 60 feet high.

Toxicophlea spectabilis is flowering profusely now, and dispensing a fragrance of a less oppressive kind than a Gardenia, or even a Stephanotis. Its crown of white tubules springing from the ovate, glistening coriaceous leaves commands instant attention. Another capital plant of different character, requiring heat however, is Tillandsia lucida. Its stiff, erect peduncle is thrown well above the Dracaena-like foliage, and carries a flower of unusual brilliancy. It is of bluish-violet, and "kills" all colours in juxtaposition.

The Orchids, and particularly the Cyripediums, are doing well. Both the Schenipedium section and the formal slipper section are fairly well in flower. There was a fine variety of C. villosum and C. Gerningianum. The backward variety of Calypso was noticeable by reason of its giant pouch. J. A.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 22.—The annual general meeting of this Society took place at Anderson's Hotel, Fleet Street, E.C., on Monday last, Mr. R. BALLANTINE (one of the Vice-Presidents) in the chair, there being a very large attendance. The annual report, read by the Secretary, Mr. R. DEAN, dealt prominently with the Jubilee Celebration of that year, which report states was carried out with a measure of zeal beyond the most sanguine expectations of its promoters, and which had enabled the Committee to make an addition £10 to the Reserve Fund.

The conference was well attended, and the papers read form admirable additions to the literature of the Chrysanthemum. The report deals also with the presentation of a Bronze Jubilee Medal to every society in affiliation with it in October last, the publication of the Jubilee Edition of the Gardeners' Chronicle, the work of the National Committee, the foreign relations of the Society, and the work of the Floral Committee. Since Jan. 1 of last year 13 fellows and 175 ordinary members had been elected, and 27 societies admitted to affiliation, among them that of Hanburg, the first Chrysanthemum society formed in Germany. A resume of the financial statement was given last week. The sum of £287 11s. was received as special prizes, £300 10s. as contributions to the Jubilee Fund, including £100 from the Royal Aquarium, in addition to the usual contribution of £200 from the directors. Special prizes amounted to £494 7s. 6d., out of necessary expenses, £21 4s. 4d. income for the year, inclusive of the balance in hand at the beginning of the year, £611 1s. 10d. On the other side prizes and medals had been awarded to the amount of £89 18s., and the remainder was made up of medals to affiliated Societies amounting to £249 8s. 6d., judges' fees, cost of banquet, expenses of management, show expenses, &c. The reserve fund now stands at £101 18s. £100 of which is on deposit at the Bank. The Report and Financial Statement were mainly unopposed.

In the course of the evening the two secretaries, Messrs. R. DEAN and C. H. PAYNE were presented each with a gold Jubilee medal and an appropriate address in recognition of their work on behalf of the Society. Silver-gilt Jubilee medals to Messrs. B. WYNN and F. W. SANDERS, respectively chairman and vice-chairman of the Committee during the past year; a Silver Jubilee medal to Mr. C. H. PAYNE as editor of the Gardeners' Chronicle, and a similar award to Messrs. R. BALANTINE, T. BAYLI, J. WILLIAMS, D. B. CRAIG, W. H. LEE, H. J. JONES and A. TYLOR, for services rendered in various ways.

Mr. ROWEN SANDERS was re-elected as President; Mr. J. K. STEVENSON, Treasurer; Mr. T. W. SANDERS as Chairman, and Mr. F. WATKINS, Vice-Chairman of the Committee; Mr. R. DEAN as General, and Mr. C. H. PAYNE as Foreign corresponding Secretary; and Mr. A. E. SWAIN as Auditor, in the place of Mr. G. J. Ingram, retired by rotation.

A large number of candidates were proposed for election to the thirteen vacancies on the Committee, and the result of the voting showed that Messrs. W. R. MACE, WILLIAMS, MOOREMAN, LEE, ISAMBELLE, HOLMES, CASSELL, REEVE, LYNE, NEWELL, GIBSON and HOWE had been returned. Votes of thanks were passed to the President, the Treasurer, and other officers, and to the Chairman for presiding.

PICEA NIGRA.

This tree, commonly known as Black Spruce, is readily recognised by its regular conical outline, slender, very gradually tapering stem, dark bluish-green foliage, and usually plentiful supply of small, ovate-shaped, purplish cones. Some of the largest specimens I have seen are growing close to the London and North-Western Railway, near Bangor Station, in Carnarvonshire. These trees range from 40 to 55 feet in height, with stems averaging 15 inches in diameter near ground-level, the taper throughout the entire length being very gradual, and is all the more pronounced on account of the trunks being branchless usually for three-fourths of their length. Curious enough, these trees are growing not in swampy soil, as is generally associated with the Black Spruce, but in a shallow layer of vegetable mould resting on coarse gravel, and in company with probably the greatest number of the largest specimens of

Pinus Laricio that are to be found anywhere in this country—nine trees growing in a space of 20 square yards averaging 70 feet in height, the stems being 5 1/2 feet in girth at a yard from the ground.

Owing to the lank, naked appearance of the Black Spruces, a large number were some years ago removed from amongst the Pinus Laricio, those around the margins of the plantation, which were the best furnished, being left as permanent standards. The timber was yellowish-white, sometimes quite white, very light in proportion to the bulk, long-grained, and readily indented. It is of little value for constructive purposes when used out-of-doors, but for purling it has a good well.

The stem of the Black Spruce is usually straight, with roughish light brown bark, the branches slightly ascending, and getting gradually shorter as we pass from the lower to the upper whorls, thus giving to the tree a regularly conical outline. The plentiful produced leaves are somewhat quadrangular in shape, half an inch long, and persist for about five years. The cones, produced in great abundance, are oblong-ovate in shape, 1 to 1 1/2 inch long, and purplish in colour before maturity, but changing to dark brown when fully ripe. A. D. Webster.

THE FOLLOWING SUMMARY RECORD OF THE WEATHER THROUGHOUT THE BRITISH ISLANDS FOR THE WEEK ENDING FEBRUARY 26, IS FURNISHED FROM THE METEOROLOGICAL OFFICE:—

"The weather was much finer and drier than of late during the earlier half of the week; by Tuesday, however, unsettled conditions had set in, in the extreme west and north, and by the end of the week had spread to all parts of the kingdom.

"The temperature was much above the mean everywhere, the excess ranging from 2 1/2 in the 'Channel Islands,' and 3° in 'England, S.W.' and 'S.' to 9° over 'Scotland,' 'England, N.E.,' and the 'Midland Counties,' and also in 'Ireland, N.' The highest of the maxima were recorded either on the 19th or 20th, when they ranged from 60° in 'Ireland, S.,' to 53° in 'England, N.W.,' and to 52° in the 'Channel Islands.' The lowest of the minima occurred, as a rule, about the middle of the week, and varied from 23° in 'Scotland, N.,' and 29° over the 'Midland Counties,' to 29° in 'Scotland, E.,' and the 'Channel Islands,' to 34° in 'Scotland, W.'"

"The rainfall slightly exceeded the mean in 'England, S.W.,' and was just equal to it in 'England, E.,' and the 'Midland Counties.' In all other parts of the kingdom there was a deficit.

"The bright sunshine was deficient in nearly all districts, but considerably exceeded the normal in the 'Channel Islands,' and to a less extent in 'England, S.,' and 'Ireland, N.' The percentage of the possible duration ranged from 41 in the 'Channel Islands,' and from 31 in 'England, S.W.,' to 18 in 'Scotland, E.,' and to 7 in 'Scotland, N.'"

Obituary.

MRS. WATSON.—We regret to record the death, on February 15, of Mrs. Watson of Berwick House, Shrewsbury. The deceased lady was an enthusiastic horticulturist, and well acquainted with garden plants, of which Berwick House gardens contained a rich collection. Since she came to that place with her late husband, about seventeen years ago, a sum of money approaching £250,000 has been expended in beautifying the house and grounds. Her daughter, Mrs. Phillips, succeeds to the estate.

MARKETS.

COVENT GARDEN, FEBRUARY 25.

[We cannot accept any responsibility for the published reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for any omissions. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. It must be understood that the prices of the commodities, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

CUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Table with columns for flower types (Anemone, Arums, etc.) and prices. Includes sub-section for ORCHIDS-BLOOM IN VARIETY.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

Table with columns for plant types (Adiantum, Aspidistra, etc.) and prices.

FRUIT.—AVERAGE WHOLESALE PRICES.

Table with columns for fruit types (Apples, Grapes, etc.) and prices.

VEGETABLES.—AVERAGE WHOLESALE PRICES.

Table with columns for vegetable types (Artichokes, Asparagus, Beans, etc.) and prices.

MARKETS.

Prices are still tending downwards for second rate quality; supplies very heavy. Double Maincrops, 55s. to 90s. 4d.; Saxons, 65s. to 70s.; Lincoln Maincrops, 40s. to 70s.; do., Saxons and Abundance, 35s. to 70s.; do., Giants, 40s. to 55s.; Blacklands, 30s. to 35s. John Bath, Wellington Street, Covent Garden.

SEEDS.

LONDON: February 21.—Messrs. John Shaw & Sons, Seed Merchants, of Great Malvern Pond, Borough, London, S.E., write that there is now an improved market for field seeds, and regards Clover and Grass seeds, both stocks and prices stand alike at a moderate level. Spring and Winter Tares are in active request, at full rates. Ryegrass steady. Blue Pans and Haricot Beans sell more freely, but are no dearer. The new Californian Butter Beans just landed, being cheap and quick, meet with much favour. Various seed attracts considerable speculative attention, and a further advance has to be noted. Fine Rape seed is scarce. Linseed is inactive. The Mustard market keeps firm.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending February 20, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Table with columns: Description, 1896, 1897, Difference. Rows for Wheat, Barley, Oats.

FRUIT AND VEGETABLES.

GLASGOW: February 21.—The following are the averages of the prices current at market during the past week:—Fruit: Peas, 5d. per lb.; Apples, 1s. to 2s. per stone; Tomatoes, Gt. 6d. per lb.; do. Scotch, 10d. do.; Grapes, 2s. to 3s. do.; foreign, 8d. do. Vegetables: Turnips, white, 9d. per doz. bunches; do. Swedes, 1s. to 1s. 4d. per cwt.; Savoy 10s. to 15s. per dozen; Cabbages, 6d. to 8d. per dozen; do., Late, 10d. to 1s. do.; do., sorted, 1s. to 1s. 2s. do.; Cauliflowers, 1s. to 2s. per doz.; Parsnips, 4s. to 4s. 6d. per cwt.; Herbs, assorted, 1d. to 2d. per bunch; Leeks, 1s. 6d. to 1s. 4d. per dozen bunches; Mint, green, 6d. per bunch; Onions, Dutch, 3s. to 4s. 6d. per bag; do., Portugal, 1s. to 1s. 3d. per stone; do., Globe, 7s. 6d. to 1s. 6d. per cwt.; Parsley, 3s. to 4s. 6d. per stone; Broccoli, 3s. to 4s. 6d. per bunch; Celery, Table, 1s. to 2s. per bundle; do., common, 9d. to 1s.; Potatoes, best, 6d. per stone; Carrots, 3s. to 4s. 6d. per cwt.; Broccoli, 2s. to 3s. per dozen; Artichokes, 10s. to 12s. per cwt.; Cucumbers, 12s. to 15s. per dozen; Lettuce, 6d. to 9d. do.; Radishes, 12d. do.; Horse-radish, 2s. to 2s. 6d. per bundle; Mushrooms, 1s. to 1s. 8d. per lb.; Rhubarb, 4s. to 5s. 6d. per stone; Brussels Sprouts, 2s. to 2s. 6d. per stone; Spinach, 3s. to 4s. per stone.

LEVERHOPE: February 21.—Average of the prices current at the following markets: St. John's: Potatoes, 8d. to 10d. per peck; Asparagus, 6s. per cwt.; Cucumbers, 15s. each; Grapes, English, 3s. 6d. per lb.; do., foreign, 5d. to 1s. 2d. per lb.; Bines, English, 3s. to 6s. each; Mushrooms, 1s. 6d. to 1s. 8d. per lb.; Berkshire: Potatoes, 6d. to 8d. per peck; do., new, 4d. to 6d. per lb.; Cucumbers, 12d. to 1s. each; Grapes, English, 3s. to 4s. per lb.; do., foreign, 5d. to 1s. 2d. per lb.; North Hvy: Potatoes, 10s. to 1s. 6d. per cwt.; Bines, English, 3s. to 6s. each; Mushrooms, 1s. 6d. to 1s. 8d. per lb.; Rhubarb, 4s. to 5s. 6d. per stone; Brussels Sprouts, 2s. to 2s. 6d. per stone; Spinach, 3s. to 4s. per stone.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns: DISTRICTS, TEMPERATURE, RAINFALL, BRIGHT SUN. Includes sub-section for DISTRICTS.

The districts indicated by number in the first column are the following:—0, Scotland N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grassing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; 'Channel Islands.

2s. 3d. per cwt.; Turnips, 10d. to 1s. per 12 bunches; Swedes, 1s. 3d. to 1s. 4d. per cwt.; Carrots, 3s. to 3s. 6d. do.; Onions, English, 4s. to 4s. 6d. do.; do., foreign, 2s. to 3s. 1/2 do.; Cauliflowers, 1s. 3d. per dozen; Cabbages, 6d. to 1s. 1d. do.; Celery, 6d. to 1s. 4d. per roll.

TRADE NOTICE.

Mr. P. F. LE SUEUR, well known as a Jersey horticulturist, has taken over the management of Messrs. Lilley Bros.' flower, fruit, and bulb-growing estate, at St. Peters-in-the-Wood, Guernsey.

APPLE AND PEAR PYRAMIDAL TREES: *Young Beginner.* The sort of pruning hitherto pursued may be continued till the trees have arrived at a size beyond which it is not desirable that they should grow. There are then two courses open, one of which is to cut every outward-growing branch back to a lateral shoot having the proper direction; the other is to restrict the length of the terminal annual growth of each main branch to 1 or 2 inches a year. As the best fruits come from the spurs situated near the circumference of the trees, nothing is gained by leaving spurs or subsidiary shoots on the inner parts of the branches, and these should be cut off close to the branches, and all summer shoots, which arise from the branches so treated, rubbed off whilst still soft. The greater part of the pruning should be done in July and August, which will consist in shortening back to one-half their length stout shoots suitable for the extension of the trees or forming fruit spurs, the final pruning of these short-cut shoots taking place when growth has almost ceased for the season—viz, the end of September.

BLACK NODULES: *C. C.* The black nodules found in "putting mould" are a "sclerotium," or fungus, in a quiescent stage. Probably it is the same as that found in Mushroom-beds, referred to several times in this journal, under the name of *Xylaria vapararia*. Your "rotten stuff" may have been mixed with some old Mushroom or Melon-bed material, which would account for these nodules. *M. C. C.*

CORRECTION.—"CRAEGUS." On p. 119, for *var. macrantha*, read *var. macracantha*.—*Hybrid Gardenist*, p. 129, for the signature at foot read '*B. P.*'

CALLIEM PHOTODUPLICATION: *D. M. L.* We are sensible of your kindness in offering a photo for reproduction, but having figured two very fine specimens of good cultivation (see *Gardeners' Chronicle* for August 22, 1874, and March 5, 1892), we cannot entertain the proposition to figure another, excepting for some special reason.

DRACENA DRACO: *T. R.* Without seeing the plant we are at a loss to advise you. It may not be well rooted, certainly the temperature of a cool greenhouse is too low for it during late autumn and winter, and if you keep it therein, it will probably go to ground entirely. First see to the roots if any, and if necessary cut the stem to a higher point, and strike it anew as a cutting in heat. Put it in sandy soil, and keep in a stove during the cold season. When well established, and therefore furnished with numerous roots, *D. Draco* succeeds out-of-doors during the summer months.

FRESIA: *C. E. H.* It is possible that under the circumstances named, the *Fresia refracta alba* might revert to the yellowish tint of the type, though we do not remember noting an instance of its doing so.

GARBS AMONG CALCOPHARIAS: *Fungi.* Send some specimens for examination.

GRUBS ATTACKING BEGONIAS AND PRIMULAS: *J. C.* The grubs are those of a weevil, and it is very difficult to eradicate them from the soil of plants, such as Begonias or Primulas, growing in pots. Your best plan would be to sterilize the soil before using it for potting purposes. If you heat it sufficiently upon an oven or stockhole boiler the grubs that infest the turf in your district may be destroyed.

HERBS: *E. A.* Thompson's *Gardeners' Assistant*. You do not say what business; but, in any case,

we suspect you require a knowledge of the natural orders. Perhaps the book reviewed in our columns to-day would suit you; but you should, if possible, attend a few lectures first. Oliver's *Lessons in Elementary Botany* would be serviceable.

HYBRIDS: *W. N.* Undoubtedly there are natural hybrids. As to Oxlips, there are various forms, one of which is a hybrid between the Cowslip and the Oxlip; and one is considered to be the common Primrose, and one is considered to be a distinct species. There are also various wild hybrid Thistles and Orchids. It is impossible to draw any definite line between cross-breeds between so-called varieties, and true hybrids between reputed species. As Asa Gray said, species are "judgments," and all men's judgments are not the same.

LOTUS: *K. B.* Assuming that you mean a Nelumbium or Water Lily, you might grow it in a large tub in a warm-house. Plant in a shallow basket in loamy soil, the surface of which may be covered with coarse gravel, and deposit the basket a little below the surface of the water. At Kew the Nelumbiums are grown in corners of the Water Lily House in soil always saturated with water, but not deeply flooded; in fact, a swamp.

NAMES OF FRUITS: *H. T.* Apple Peasgood's Nonsuch. *C. W. S.* Pear Easter Beurré.—*J. M.* Cannot determine; too much bruised; too late.

NAMES OF PLANTS: *Correspondents not inserted in this issue are requested to be so good as to consult the following number.*—*G. E. L.* Both varieties of *Oncidium maculatum*, a tolerably common species first imported from Mexico sixty years ago, when it was known as *Cyrtorchilus maculatum*.—*W. J. S.* *Arenifloridifera*. 1, *Ophiopogon spicatus*; 2, *Polypodium japonicum*; 3, *Polypodium appendiculatum*; 4, *Adiantum capillus-veneris*; 5, *Primula verticillata*.—*P. G. S.* It is the variety known as *Cypripedium insigne Syllense*, which is distinguished by the short labellum. Yours is rather broader in the petal than usual.—*J. S.* *Oncidium lamelligerum*.—*H. J. W.* *Dendrobium fimbriatum oculatum*.

PROPAGATING WHITE MARGUERITES: *Gardener.* As soon as cuttings of fair size can be obtained, place them to the number of half-a-dozen, round the sides of a 6-inch pot, in a mixture consisting of leaf-mould and sand in equal proportion, plunging the pots in a hot-bed of 60, and top-heat of 65°. In three weeks the cuttings will be struck, and ready for potting, which should be done in 4-inch pots. If it be desired to flower them in pots, a suitable soil will consist of three parts loam, one of sand, and if the soil is of a sandy nature, one-quarter of the whole may consist of leaf-mould in place of the sand. When used for beds, autumn-struck cuttings are preferable. These should be taken about September from plants growing in the open, and pricked out in sandy soil in a cold frame, bracken or mats being thrown over the glass in severe weather—treated, in fact, the same as bedding Calceolarias. They are harder when thus treated, and much time is saved.

ROOTS OF VINES: *S. H.* The border appears to have been sodden, and the roots suffocated for want of air. The state of the roots could scarcely be worse.

SEED-BOXES, LEAF-MOULD, AND FUNGI: *Fungi.* It is not surprising that fungus gives trouble when such ill-prepared leaf-mould is employed as that which you sent to this office. Leaf-mould is an almost indispensable ingredient in potting-soils, and should not, in a general way, be employed, except in a well-decayed condition; and to obtain it, the leaves of Oak, Chestnut, Beech, Birch, Willow, Alder, and Hornbeam, being more suitable than those of the Sycamore, Plane, Maple, Walnut, Elm, and others of like soft texture, should be gathered into heaps and enclosed by sheep-hurdles or similar contrivance, so as to prevent their being blown about. It will take from two to three years to thoroughly decompose a heap, and in the second year the heap should be turned with leaf-forks, and the decayed central portion separated from the rest, sifted through sieves or a screen, with a 1/2-inch mesh, the rough part thrown back on the heap, and the finer part put under cover for another year before using it. The heap of leaves, now partially rotted, should be mixed together and formed into a new cone shaped heap, to still further decay. The addition of some warm stable-manure will, at this stage, aid fermentation and rotting. At the end of the second year the whole will be fit for another

turning over and separation of the decayed portion as before, and at the end of three years the entire heap will be reduced to the condition of leaf-mould. Each year should have its separate leaf-heap, and decayed and partially decayed leaf-moulds should be put in heaps kept apart, and the year of collection marked with a stout label. Chips of soft wood, any kind of bark, soft shoots, small branches, old Pea and Bean-sticks if rotted in a heap out-of-doors, and similarly treated, form, when quite decayed, a capital material for mixing with the peat and loam used in potting *Ferax*, *Athurium*, *Pothos*, terrestrial Orchids, *Gloxinia*, *Acichenes*, *Camellias*, New Holland plants of nearly all species, *Dracenas*, &c. You might try the use of decayed clear lime-water in arresting the growth of the fungus in the seed-boxes.

THE HEAT OF HOTBEDS: *G. H.* The Melon succeeds on a bed having a steady warmth of 80° The Cucumber scarcely needs so much heat, and 75° to 78° suffices. With stable-manure alone, the heat will be of short duration once it has declined to these figures, but it would be much more lasting if you could mix with the latter an equal quantity of the leaves of the Oak, Chestnut, and Beech. Failing these, the necessary degree of heat may be kept up by means of linings of properly-prepared stable-dung applied when the heat of the bed, taken with the plunging thermometer, is seen to be declining.

WINDOW BOXES IN A NORTH ASPECT: *H. S.* Satisfactory results would be obtained by planting the following:—Cut back *Fuchsias*, not less than two years old; *Cinerarias*, raised especially for the purpose; some of the dwarfier *Asters*, or *Michaelmas Daisies*, as *A. acris*, 2 feet, white; *astivus*, blue, 2 feet; *alpinus*, 1 foot, bright purple; and *albus*, albus, late purple, 1 foot; *argenteus*, purple 1 foot; *dimissus*, white, 2 feet; *leucosifolius*, white, 1 foot and less in height; *peregricus*, bluish-purple, 1 foot; the annual "Asters," *Callistemma hortensis*, might also be employed, growing them in pots or in beds in a sunny place, and transferring them to the boxes after the plants had got well into bloom; the same might also be done with single and double flowered *Pelargoniums*, such as are ordinarily used in the flower garden, except that pot culture only would have to be resorted to; various species of *Lily* might be similarly treated, choosing those of moderate height, as *Cesbeii*, *concolor*, *japonicum*, *roseum*, and the varieties of *L. speciosum*. Shrubs with variegated foliage might be sprightly used as *Isolde* to the flowering plants, as *Azalea*, *Euonymus*, *golden Tili*, and *Cornus silver and golden Privet*, &c. As *Tallies*, *Linaria cymbalaria*, *Scilla Scoboldii*, *Lithospermum prostratum*, *Lysimachia Nummularia* (Moneywort), &c., might be used.

GARDENING APPOINTMENTS.
MR. G. HENDER, previously employed in the gardens Little Kirby Hall, Melton Mowbray, as Gardener to Mr. FAWCETT, has been appointed Gardener at Bury, Derbyshire.
MR. J. HAWKINS, and recently General Foreman at Hughman Court Gardens, Gloucester, as Head Gardener to Col. HAWKLEY BARLEY, Tugbush Manor, Woburn, Bedfordshire.
MR. J. FARO HARRISON, late General Foreman at Bridge Hill Gardens, Derbyshire, as Head Gardener to R. O. LAMB, Esq., West Denton Hall, Stockwood-on-Tyne.
MR. HENRY ARMS, Gardener to W. PARK, Bocking, Esq., (formerly, Shipton-on-Strou, previously Foreman at Dugdale's Gardens, Clipping, Norton, and Busing Park Gardens, Alton, Lincs, has been appointed Gardener and Bailiff to Mrs. BUCKINGHAM, Buckingham Hall, Bury.
MR. NATHAN SUTHER, late Head Gardener at Dunckerston Castle, as Head Gardener at Droghda, Co. Kerry.
MR. JAMES DENBAR, from Beechhill Nurseries, Ealing, as Head Gardener at Dunckerston Castle, Co. Kerry.

THE

Gardeners' Chronicle.

SATURDAY, MARCH 6, 1897.

RECENT CHRYSANTHEMUM LITERATURE.

THESE are, of course, many readers of the *Gardeners' Chronicle* who remember the Centenary Festival and Exhibition held under the auspices of the National Chrysanthemum Society in 1890. They will, no doubt, recall the prophecy of certain well-meaning but happily short-sighted people who declared that, after such an exceptional effort, the popular flower from the Far East was destined to enter upon a period of decline, and that little else remained to be done to maintain its popularity.

But these worthy folk could not foresee the advent of a Calvat, whose entrance into the ranks of seedling-raisers since the date mentioned has almost entirely reversed the old order of things; nor could the prophets be expected to count upon the extraordinary exertions of the executive of our leading Chrysanthemum Society to celebrate, as was so well done last November, the fiftieth anniversary of its existence. But to those who know the Chrysanthemum best, its history since its first introduction into Europe more than a century ago is little else than a series of surprises and departures from the beaten track.

A very fair idea of the importance of any subject, be it floral or otherwise, may be gained from its literature. Since the year in which the centenary was celebrated with so much success, the Chrysanthemum has been dealt with in a most liberal manner by the horticultural press both in England and America.

Apart, however, from these fugitive contributions, many of which are of a high order of merit, the Chrysanthemum has received a large measure of support from the pens of authors of independent treatises. It is not an uncommon thing now-a-days to find some of the leading nurserymen giving their trade catalogues a semi-literary appearance by including essays on cultivation, and occasionally matter of a more technical nature. Amongst some of these commercial publications it is difficult at times to say which should be regarded as mere trade catalogues, and which should be placed on a higher level, because the main object of them is to sell the goods of those who are responsible for their publication.

Without, however, attempting to draw any such line of demarcation, it will easily be seen that besides the higher class of nurseryman's catalogue, the literature of the Chrysanthemum has received substantial additions from the pens of authors whose direct object has not been the advertisement and sale of plants. Upwards of forty independent books, pamphlets, and treatises dealing with the cultivation, description, exhibition, or other subjects allied to the Chrysanthemum have been published by horticultural writers during the past seven years, a number never equalled in any similar period during the

history of the flower. They vary from mere pamphlets to works of some pretensions, and have been contributed from many sources at home and abroad. This fact is well worthy of mention to dispel any lingering mistaken notion that may even now exist as to the approaching decline of the popularity of our favourite.

Chief among cultural treatises are the handy manuals by Mr. Edwin Molyneux, Mr. J. Morton, and M. Anatole Cordonnier, the representative writers for England, America, and France. Among the descriptive lists, official and otherwise, the catalogues of the National Chrysanthemum Society, the American Chrysanthemum Society, and those compiled by M. de Meulenaere, of Ghent, deserve a special mention. Then, from an artistic point of view, such publications as Mr. Inai's *Kikkwa Meiji-Sen*, Mr. Ogawa's *Chrysanthemums of Japan and the Golden Flower, Chrysanthemum*, a very finely-executed American art volume, occupy a high rank, and although not in any case of a practical nature will be much appreciated and valued by those admirers of the Chrysanthemum who have also a tincture of the bibliophile in their constitutions.

The years most prolific in additions to the bibliography of the Chrysanthemum since the stir consequent upon the centenary celebration are as follows:—1891, when six new books were published; 1892, when there were eight; 1894, when nine new works appeared, and last year when there were as many as twelve.

Of these twelve, England contributed five, and it will be almost needless to remind the reader that early in the year, Mr. R. Owen and Mr. W. Wells issued handy little cultural guides, which were shortly afterwards followed by Mr. H. J. Jones' excellent *Chrysanthemum Album*, a new departure in every respect. The National Chrysanthemum Society, as a part of its jubilee programme, published a new and revised edition of its official catalogue, and there was also a small pamphlet on Chrysanthemum culture in the Salisbury series of garden produce handbooks.

The French were also responsible for the same number. M. Anatole Cordonnier's *Le Chrysanthème et la Grande Fleur*, is at once one of the best works of its kind from any source, and it is not at all to be wondered at that a second edition has just recently been called for. MM. Chabanne and Choulet as joint authors, and M. Raphaël de Noter were the next in the field with small cultural essays, and then M. Georges Truffaut issued in separate form his *Étude sur la Culture et la Végétation des Chrysanthèmes*, which was originally printed in the *Journal of the National Horticultural Society of France*. The last to be noticed from France was a most interesting Monograph by M. Henri L. de Vilmonin, entitled *Le Chrysanthème, histoire, physiologie et culture en France et à l'étranger*, in which this eminent horticulturist very fully and ably deals with the subjects of his essay in a most delightful manner, and the work has the advantage of being embellished with a goodly number of well-executed and characteristic wood engravings.

Belgian Chrysanthemum literature in separate form was represented by one work only, viz., the second supplement to M. O. de Meulenaere's valuable catalogue. This gentleman has earned the thanks of all literary Chrysanthemum growers by the preparation of his useful catalogues, in which are to be found much matter relating to dates and raisers' names that cannot be found elsewhere, and which render his catalogues of infinite service to those who write for the press.

The last new Chrysanthemum treatise for 1896 to be noticed, emanates from the United States. It is Bulletin 112 of the Cornell University Agricultural Station, and bears the title of *The 1895 Chrysanthemums*, by L. H. Bailey, Wilhelm Miller, and C. E. Hunn. It is similar in style to the one from the same source the previous year, called *Recent Chrysanthemums*, and contains much matter of interest to other than American growers.

But quite separate and distinct from the above-mentioned works, one of the most promising features in connection with Chrysanthemum literature is the recent appearance of periodical publications. One would have thought that we in England, with all our protestations of affection for the flower would have long since started and loyally supported a weekly or monthly magazine specially devoted to the dissemination of Chrysanthemum news. The French, however, simultaneously with the founding of their three new Chrysanthemum societies, have already shown us the way.

The first is the *Nord Horticole*, the official organ of the Northern French Chrysanthemum Society, a bright little monthly that was first issued in May last, and which ever since has very fully dealt with the Chrysanthemum in every conceivable manner, giving portraits and biographical notices of many of the principal French growers. The special double Chrysanthemum number for November last was full of interesting contributions, and this publication, as a Chrysanthemum journal, occupies a prominent position.

The Chrysanthemum section of the National Horticultural Society of France has also issued two numbers of a new bulletin dealing exclusively with the operations of that section. Reports of visits to the establishments of well-known growers, selected lists of varieties for various purposes, and other articles have appeared; but unfortunately, up to the present, the interval between the numbers is a somewhat lengthy one.

The last of the new French serial publications is entitled *Le Chrysanthème*, and is the organ of the French National Chrysanthemum Society. This was first issued in September last, and has been regularly supplied to members every month since. It is edited on somewhat similar lines to the one just mentioned, but is a little more comprehensive, for the contents are not exclusively confined to the operations of the society which issues it. The title is well chosen, and the work itself needs but a little expansion to become a thoroughly representative Chrysanthemum journal; and is a most creditable publication, considering the Society is only a little over the first year of its existence.

Such is a brief outline of the literary activity displayed in a popular cause during the past twelve months, or thereabouts; and, in my opinion, it is the surest guarantee that we are as yet a long way from the anticipated decline of the flower that, considering its season, has no rival worthy of the name, *C. Harumoto Pagan*.

NEW OR NOTEWORTHY PLANTS.

CYRANTHUS MARIAN.

AT last, after some years of endeavour in crossing species of the *Monella*-section of *Cyranthus*, I have succeeded in producing one raised from intercross by pollen of *C. Bucki*, which that great authority on the genus, Mr. J. G. Baker, at once pronounced "a very fine plant, and an excellent addition to the genus, notwithstanding its hybrid origin." In it-

general features it may be said to have the strong habit and robust stature of *C. Tuckii*, bearing a many-flowered umbel (not few-flowered, as in *C. lutescens*), with much of the yellow colour and graceful habit of *C. lutescens*, which it also follows in the recurved or spreading character of the perianth segments, and in commencing to flower very early in the spring. The leaves, which are produced together with the flowers, are bright green, and when mature they measure about 1 foot in length. The stout peduncle is nearly 2 feet in height, and bears an umbel of eight very showy flowers, on pedicels varying from 1 to 1½ inch in length. The curved perianth-tube is 2 inches long, and the segments are spreading. The ground colour of the flower is yellow, the tube is suffused with light pinkish-orange, which deepens as it approaches the perianth-segments, which are a dark shade of scarlet at the back, and yellow tinged with red on the face. The bicarinate stamens are just visible in the tube, from which the style slightly projects. I name it after my little daughter, and thus keep it clear of the true species. In crossing these plants I have had some curious experience, which tends to confirm my previous experiences, viz., that the hybridist should be shy of crossing a free-seeder, or rather of persisting in crossing it after failure has been demonstrated. I tried crossing several species, both of the *Monella* and the *Gastroneura* section, but either they did not produce seeds, or the weak seedlings raised from the seeds failed to live. At last I imported a very free-flowering but rather low form of *C. angustifolius*, which I named *C. a. aurantiacus*, and on its flowering, after carefully removing its own anthers before they were of use, I crossed it with several species, and it took equally well with the pollen of each. But on the seedlings flowering they were one and all *C. angustifolius aurantiacus*, and nothing else. Occasionally, either in the bud or in the fading flower, they sometimes exhibited faint traces of other influence, but no one but a keen observer who knew how they were produced could distinguish it. On trying it again, the result was the same. There seems to be a strange individuality about some species which we may regard as sectional types, which prevents perversion, the first generation, at least. I have had several marked instances of it. *James O'Brien.*

PATTON'S SPRUCE.

By the increasing number of travellers who explore the high mountains of the Pacific States, which are its only home, the lovely Mountain Hemlock is now usually known as Patton's Spruce. Perhaps best considered a Hemlock, this tree differs from other Hemlocks in its long, narrow cones and in its more acute leaves, usually keeled on the upper surface, and its bilobed pollen grains; and in general appearance it is one of the most distinct and beautiful of the North American Conifers.

Tunga Pattoniana, as botanists call this tree, was discovered only about forty-five years ago near Mount Baker, in Northern Washington, by the Scotch collector Jeffrey, and was named out of compliment to George Patton, a Scotch lawyer, who was given to the cultivation of exotic trees, and was one of the subscribers to the fund which enabled Jeffrey to explore the forests of North-western America.

Patton's Spruce is now known to range from Alaska, where it grows at the level of the sea, southward along the mountain ranges of British Columbia, west of the continental divide, the two slopes of the Cascade Mountains of Washington and Oregon, and the California Sierra Nevada, where probably, on the upper waters of some of the tributaries of King's River, it finds its most southern home. It is a tree of high altitudes, and, except at the extreme north, it is found only near the timber-line, forming, with *Pinus allicaulis* and *Abies lasiocarpa*, extensive forests.

Patton's Spruce is a tree of marvellous grace, with drooping branches clothed with thickly-clustered leaves, abundant elongated narrow cones, which hang on slender, spray-like branchlets, and on some individuals are bright purple, and light yellow on

others in the same grove. The foliage, too, differs in colour, being on some trees dark green, and on others light blue-green, a peculiarity which has led to some confusion of nomenclature, the blue-leaf form often appearing in gardens as *Teuga* (or *Abies*) *Hookeriana*.

Patton's Spruce grows in the greatest perfection on the slopes below Crater Lake, in the Cascade Mountains of Southern Oregon, forming here extensive and nearly pure forests, in which individual trees 100 feet high, with stout massive stems 5 or 6 feet in diameter, are abundant. Such a growth is probably not exceptional, and this tree is abundant and conspicuous at the timber-line of Mount Hood, Mount Ranier, and on the Selkirk and other mountains of British Columbia. On Mount Ranier, with *Abies amabilis* and *Abies lasiocarpa*, it forms a large part of the forest growth, growing above the banks of glaciers in great luxuriance. Some idea of the upper forest-belt on Ranier can be obtained from our illustrations in this issue; that on p. 6 displays the snow-covered summit rising 8000 feet above the timber-line, with scattered trees of Patton's Spruce on the slope; in the foreground, and in the illustration on p. 7 the trunks of this tree are displayed in more detail.

FIG. 42.—*TSUGA PATTONIANA*: CONE, SCALE AND SEEDS.

In Washington and Oregon, Patton's Spruce grows at elevations of from 5000 to 6000 feet above the sea-level, but further south the timber-line is carried higher; and John Muir, who describes this tree in his *Mountains of California* as the "most singularly beautiful of all the Californian Conifers," found it growing on the Sierras up to 10,000 feet altitude; and on the edge of Lake Hollow, at an elevation of 9200 feet, measured a trunk 19 feet 7 inches in circumference at 4 feet above the ground. "No other of our alpine Conifers," he tells us, "so finely veils its strength. Its delicate branches yield to the mountain's gentle breeze, yet it is strong to meet the wildest onsets of the gale—strong not in resistance, but in compliance, bowing snow-laden to the ground, gracefully accepting burial, month after month, in the darkness beneath the heavy mantle of winter. Every tree-lover is sure to regard it with special admiration. Apathetic miners, ever seeking only gain or gold, stop to gaze on first meeting it, and mutter to themselves, 'That is a mighty pretty tree.' The deer love to lie down beneath its spreading branches; bright streams from the snow that is always near ripple through its groves, and *Bryanthus* spreads precious carpets in its shade. But the best words only hit its charms."

Introduced into Scotch plantations by its discoverer, Patton's Spruce has shown that it is fairly adaptable to altered climatic conditions, and it may now be seen in many European collections; and although it has not yet had sufficient time to attain maturity in

cultivation, it is an ornamental tree of much promise in several European countries. Patton's Spruce, moreover, is one of the comparatively small number of the Conifers of the Pacific States which thrive in the east; and although, like most alpine Conifers, it grows extremely slowly at the sea-level, it has for several years withstood without injury the changeable winters and dry summers of the New England climate. *Garden and Forest.* [The woods illustrating this species first appeared in the *Gardeners' Chronicle* on July 2, 1892, and June 3, 1893. Ed.]

THE ROSARY.

ROSES IN EARLY SPRING.

We have many kinds of exotic plants in our garden, some of them rare, and many of them beautiful; but there is nothing in the greenhouse or hothouse equal to the Roses which are now in leaf and flower. The green leaves, with a small globe of water at the tip of each serrature, are very beautiful in the early morning, and how restful to the eye! By the end of February we always begin to cut the flowers of our Roses, and continue to do so until Roses are plentiful out-of-doors. We have no convenience for planting-out Roses under glass, therefore the plants must be grown in pots, and we have no place that can be specially set apart in which to grow Roses for forcing. But where there is a will there is a way, else that may seem difficult. My practice is to prune the Roses about October. The earliest vinery is started about the middle of November, and the Roses, which have been carefully prepared, are started in this house in a minimum temperature of 45° to 50°. I like the old-fashioned method of putting a heap of fermenting manure inside the vinery; this not only gives off ammonia-like moisture sufficient for the Vines, and saves the frequent syringing and "damping down" which causes an irregular degree of moisture in the atmosphere. Some cocoa-fibre or spent Mushroom-bed may be placed on the top of the manure-heap, and on this the Roses are stood. Care is taken not to allow a violent heat to burn the roots, which might easily occur if rank stable-manure is used. If the manure is fresh it ought to be thrown into a heap and be turned over two or three times at intervals of five or six days before taking it into the house.

The only pests that attack the leaves thus early are the green aphid and mildew; a very light dusting of flowers-of-sulphur destroys the latter, and the aphid is killed by fumigating with tobacco-smoke. When the flowers are pretty well advanced, it is better to remove the Roses to a warm greenhouse, for by that time the temperature of the vinery will have advanced to about 60° minimum, and flowers opened in this temperature in February are flimsy. Care should be taken of the Rose plants, so that the foliage may be kept in good condition; and when the flowering period is over, the plants must be carefully looked after until the wood is well ripened.

This is what I alluded to above as being "careful preparation," for how often do we see the plants turned out-of-doors as soon as they have done flowering! Now, it is a fact that few plants are attacked by so many pests as are Roses. Green-fly attacks the points of the young growing shoots, and red-spider turns the older leaves of a rusty-brown colour; while the troublesome fungoid growths, Orange-fungus and mildew, are seldom absent. I saw a collection of pot Roses once at the end of September, and every plant was infested with all four pests. Under such conditions how could the young wood become developed or well ripened? Hybrid perennials are comparatively hardy, and do not suffer much from a drizzle of rain, or from cold east winds after April comes in; but it is not so with the Tea-scented varieties. They require more shelter, and should not be placed out-of-doors until the end of May—indeed, it would be better if they were not placed out-of-doors at all, even in summer; but in that case they should be given plenty of space, and exposed to light and air. The plants should be re-potted in August, to allow the roots to grow freely

into the fresh soil before the end of autumn. A compost of good turfy loam four parts, one part leaf-mould, and one part decayed manure, with about a 6 inch potful of bone-dust to each barrow-load of the compost will suit them well; but Tea Roses, like a rather lighter material, which may be obtained by the addition of some light fibrous peat. Pot rather freely. *J. Douglas.*

ENGLISH ORCHARDS.

The following is the text of Mr. George Gordon's lecture on "English Orchards," given before the Society of Arts on Wednesday, March 3—

You, I am fully persuaded, be not less gratifying to you than agreeable to myself were I in a position to speak this evening in terms of warm praise of the present condition of English orchards, and in a spirit of hopefulness with regard to their possibilities. It would also be extremely pleasant if I could, with strict regard to truth, describe them as having no superiors in any part of the world, and as so rapidly increasing in productiveness as to justify the hope that the time is within a measurable distance when they will yield supplies sufficient to meet the large and increasing demand for fresh fruit. Still further, I should be glad to speak of them as so judiciously planned and skilfully managed that they might serve as models for the guidance of colonial and foreign fruit-growers. It would not be less pleasant to dwell upon the glorious pictures the orchards present in spring when the trees are encrusted with their snow-white or delicately-tinted blossoms; and in autumn when the supple branches are bending beneath their precious burden of fruit, and also to refer to the profit their crops give their cultivators, and the satisfaction the fruit affords those who have to depend upon the markets for their supplies. Unhappily, most of these pleasures are for the present denied me. Instead of giving expression to feelings of satisfaction with what has been accomplished by owners of orchards, it is my duty to place before you facts which to those not fully conversant with the subject might well appear incredible in the light of the remarkable advance that has been made in all branches of industrial activity during the past half-century. I have, indeed, to bring before you a state of things in relation to the orchards of England, so grave as to deserve the most careful and consideration of all who are interested, however indirectly, in the prosperity of the owners and tillers of the land; and I earnestly hope, as one result of this meeting, that attention will be aroused to the necessity of a drastic reform in orchard management.

The question of fruit culture is one that has for many years attracted a large share of my attention, and I have endeavoured to keep it constantly to the front, not only in discussing its various aspects in the pages of the *Gardener's Magazine*, for whose policy and management I am responsible, but, as far as any somewhat exacting professional duties will permit, by work in other directions. Ten years ago I initiated a series of conferences at the Crystal Palace, which were held in conjunction with the autumn exhibitions of fruit, and at the gathering in the autumn of 1890 I submitted a report on the condition of fruit culture in Ireland, this report being founded on investigations that I had made by myself, and of my own cost, in the course of the previous summer. The success of these conferences stimulated the Royal Horticultural Society, the Fruiteers' Company, and several of the principal provincial horticultural associations into activity, and as the result of the combined efforts the area under fruit has been increased during the decade by 18,000 acres, and considerable improvements have been effected in methods of procedure so far as they relate to market garden plantations. With the exception of the first-mentioned society the several associations appear to have grown "weary of well-doing" in the advancement of profitable fruit culture, and have returned to their old methods, and the Royal Horticultural Society has shrunk from grappling with the somewhat difficult question of the orchards. We are therefore now in the position of having a continuously increasing demand for fruit in all our populous centres, with fens of thousands of acres of the finest land in England deserted by fruit trees in so dilapidated and wretched a condition that they cannot possibly yield the amount of the ground, without one of the several hundreds of scoundrels that ostensibly exist for the advancement of horticulture and agriculture being engaged in making a systematic endeavour to improve their condition. I regret also that, with some notable and praiseworthy exceptions, Technical Education Committees are not less oblivious of their responsibilities in this matter than are the societies immediately concerned with the affairs of the farm and garden. In proof of this, I have only to point to the fact that in counties where the orchards are in a terribly neglected state, large sums of money are annually expended in teaching painting on china, music, dancing, and similar accomplishments, while not a penny, so far as I have been able to ascertain, has been spent on the education of the occupiers of orchards in their management and the utilization of their products, which would have been the chief object of societies that profess to foster horticulture and agriculture, and of education committees in counties, should be to diffuse information upon matters having direct relation to the work of those engaged in the cultivation of the land; for not until the cultivator is well informed upon the principles and practice of his art, can he hope to obtain a full return for his labours.

Unfortunately these public bodies do not, as a rule, hold the same views with regard to their duties as myself, and considering it to be utterly futile to expect them to take the initiative in the adoption of some means by which an improvement could be effected in the orchards, I carefully considered what could be accomplished by private effort. As the doctor must diagnose a disease before he can properly prescribe for his patient, it appeared to me that one of the first steps towards an amelioration of the condition of our orchards would be to direct attention to the state of neglect and decay into which they have fallen by means of absolutely exact reports founded upon careful investigation.

proper performance of the duties. The investigations extended over nearly two years, and as the result of the inquiries I have been able to publish full reports upon twenty-four typical English counties. In passing I would mention, as indicating the care and thoroughness with which the investigations were made and recorded, that, although I have received several kind notices in reference to the reports, in no instance has their accuracy been called into question. I had previously gone over much of the ground myself, and it was a great satisfaction to me to find how closely my instructions that the condition of the orchards examined should be described with exactitude and without embellishment were being followed; they had need have something that will give rise to a feeling of satisfaction in connection with the orchard question, for the record is one that can hardly fail to fill the mind with profound regret. It brings into strong relief the fact that while in the whole of the counties fruit is grown in private gardens, and in many market garden plantations in accordance with the most advanced practice, orchards have for the most part been so neglected as to have become a blot upon the landscape and a discredit to their owners. I shall not weary you by reading any considerable portion of the reports; but to convey an adequate idea of the state of things that now obtain, it will be necessary to give a few short extracts from those on the counties specially favourable to the profitable cultivation of fruit.

As you are well aware, it is a quite common occurrence to speak of Kent as the "Garden of England," and so far as our hardy fruits are concerned, it might justly be described as the "Garden of Wines." For not only are such crops as cherries, Pears, and Plums be grown to a higher degree of perfection than within its boundaries. It is a matter of common knowledge that the most advanced practice obtains among a section of the fruit growers of Kent. Yet what do we find? For an answer to the question I must turn to the report on the county:—"An orchard of standard Apples soon gave me material for survey; the field was one of some 20 acres, and the trees seemed to be about fifteen years old. I was struck by their miserable appearance. In the whole field there was hardly one that looked healthy, and with but few exceptions they were dying of canker, being covered with great gaping wounds and leafless branches. Some were bearing fruit, but in appearance and quality it was of the most wretched description. It will go into the market, of course, stunted, speckled, and discoloured as it is, and come into competition with large, fresh-coloured American produce." In the reference to another district, we are told:—"I came upon as instructive an example how not to bring fruit growing as could be found in the whole kingdom. A peculiar whiteness on the trees, as though they were silvery with a fall of summer snow, attracted my attention, and on getting amongst them I found, as I expected, that they were attacked by American blight. But what on attack? The sight of those trees, thick with heavy masses of the lathsome pest on trunk, limbs, branches, and spurs, will not quickly fade from my memory." Speaking of the common Black Plum which is so largely grown in some parts of Kent, more especially in the Ash and Sandwich districts, the report states, and I quote it as bearing upon a point to which I shall have to refer later:—"We have heard the old story about Plums rotting on the trees. We shall hear it again until some of the hundreds of thousands of trees, the produce of which a few public will hardly buy at any price, are sent away or grafted with sorts that the public want." If we find, in the fair county of Kent, trees dying in consequence of their having been improperly planted, or from insect infestation, and of orchards that are unpromising because they consist of inferior varieties, it is not surprising to find in preceding westward, that the orchards of Sussex, Hampshire, and Dorset, are also in a wretched plight. I do not, however, purpose detaining you with extracts from the reports on these orchards.

(To be continued.)

METHODS OF PROPAGATION.

(Continued from p. 147.)

HERBACEOUS PERENNIALS.—The white and other varieties of the useful Everlasting Pea (*Lathyrus latifolius*) are best increased by their roots, and the former should have a place in every garden and cool conservatory, as its abundantly-produced pure white flowers are beautiful and enduring when removed from the plant. *Lathyrus tuberosus* can be indefinitely increased by division of the roots, cutting 1 to 2 in the small tuberous seedlings, which contain bacteria, which of late have founded a new theory of the nitrification of the soil. The increase of some species of herbaceous perennials is possible only by means of the roots, and it was a long time before I hit upon the right method for that useful and pretty *Lycium*, the double form of *Lycium viscaria*, which in its mature growth, is what is generally called "pipp," i.e., hollow, and will not strike even if the young shoots are taken when they first spring from the crown in the early period of growth, nor will the small laterals with a heel of old wood; but take up the plant, and

FIG. 43.—ISCHA PECTINOSA.

Shoot with male flowers; a flower magnified; cross section of leaf, and other details. (See p. 150.)

tions. It was accordingly decided to investigate them on behalf of the *Gardener's Magazine*, and publish the results of the investigations. The task was one not to be lightly entered upon, and I confess that it gave me much anxiety. To be of value the investigations had necessarily to be made in a thorough manner by an expert possessed of keen powers of observation, and also well versed in every phase of fruit culture, and full investigations carried out on these lines over the whole of England could hardly fail to prove very costly. Happily, the proprietors of the journal readily consented to the heavy expenditure being made, and I was fortunate in engaging as special commissioner an expert possessing in an eminent degree the qualities essential to the

shake out most of the soil from among the root-fibres, and then select the stoutest roots and cut them into pieces about 3 inches long, and put them firmly round the rim of a 32-sized pot, water in to render them firm in the soil, then put into a cold frame to enable them to gradually callus over. When this takes place, they may be left to Nature, but do not despair of success if no result is shown quickly, as oftentimes there is no show of growth for at least twelve months, though the fragments of roots keep sound and plump. To hasten matters, plunge the pots up to the rim in a half-spent hotbed, and cover with glass, giving air now and then to prevent a minute fungus (mildew) attacking them. When the young shoots appear from the crown, afford air to ripen these, and when this has occurred, the plants may be potted singly or bedded out in a suitable nursery bed. During the growth look constantly for slugs big and little, which attack the young growing shoots, eating them off close as fast as they appear.

THE YUCCAS,

with their grand spikes of creamy-white flowers, exhibit to the observant eye a fitness for propagation by means of the roots, as, especially when a plant has flowered, numerous buds appear on the larger roots, all of which, when removed, form good plants in a short time. I would more especially name *Y. stenophylla*, *Y. glauca recurva*, and *Y. gloriosa*; whilst *Y. filamentosa* and *Y. vivipara* increase themselves with sufficient rapidity as a rule, and are more at home in the herbaceous border than solitary plants on a lawn. The varieties of *Y. aloefolia* are cool conservatory plants, but may be propagated in the same manner.

CLEMATIS.

Roots to serve as stocks for grafting purposes are raised from divisions of the roots of *C. vitalba* and *C. viticella*, but these are more often raised from seed than by division.

BIGNONIA RADICANS MAJOR

and *B. grandiflora* are grafted on *B. radicans*, and the fine greenhouse climbers, the *Teomans* (*Bignonia*s) succeed on the same kind of stock. I name this *en passant*, as I think it was omitted from my paper on "Inside Grafting."

I will conclude this section of my notes by merely appending a list of plants easily propagated from their roots, though I do not assert that this by any means exhausts the list:—*Anemone japonica* and its varieties, *Doronicum vernum*, *Anchusa italica*, and other *Achusas*; *Acaulhis*, *Achille*, *platanica*, *Aconitum*, *Asphodelus ramosus*, by tuber-bearing roots; *Bocconia cordata* and *B. japonica*; *Calystegia pubescens*, fl. pl., and other varieties; *Catananche*, *Campanula* in variety; *Centaurea montana* and its varieties; *Centranth*, *Chelone*, *Cimicifuga racemosa*, *Coryopsis lanceolata*, *Dicentra*, *Echinops*, *Epilobium*, *Epipactium*, *Erigeron* (*Stematis*), *Erodium*, of sorts; *Eryngium*, in variety; *perennial Gaillardias*, and *Galera* varieties, *Gaura*, *Gypsophila paniculata*, and others; *Harpallium rigidum*, and most of the other perennial Snowflowers; *Helianthus*, *Hebeborus*, in variety; *Hemerocallis*, *Hypericum*, *Iris*, all the so-called German and the rhizome-forming varieties; *Liatris*, *Ludolphia spectabilis*, *Lithospermum prostratum*, *Lysimachia clethroides*, *Lythrum*, the *Bergamots* (*Mouard*), early *Forget-me-not* (*Omphalodes verna*), *Pentstemon glaber* and 1 varieties, *Phyllis glauca*, *Platycodon* or *Wahlenbergia*, *Plumbago*, *Larpetus*, *Polygonum sachalinense* and *P. cuspidatum*; *Primula cortusoides*, and *P. acutis*, *Ranunculus acris*, fl. pl., and others; *Scabiosa caucasica*, *Senecio Doronicum* and *S. pulcherr.*, *Sidalcea* (*Malva*) *caudata*, the handsome *Stokesia carynea*, *Tinactrum*, *Tropeolum polyphyllum* and *T. speciosum*, *Tussilago farfara* and *T. fragrans*; and lastly, the brilliant half-straggly *Zonchomeria californica*.

The tuberos and bulbous plants usually found in bulb catalogues I have omitted, but many of these may be increased by division of the bulb or crown, especially the *Glaadioli*, taking care to secure a growth-bud to each portion, while the little bulbils

common to this genus found at the base of the crown are a ready means of increasing the variety, though unfortunately some of the finest varieties produce these very sparingly. *Experience*.

(To be continued.)

PLANT NOTES.

AMASONIA FUNICEA, Vahl, Verbenaceae.

This plant is a most charming decorative subject; its inflorescence being of a shining red, and the plant generally of elegant habit. It is not regular in its flowering period, but it blooms generally in winter. Like *Euphorbia* (*Poinsettia*) *pulcherrima* and *Bougainvilleas*, the floral effect of *Amasonia funicea* is due to its bracts. These are opposite upon an inflorescence often exceeding 18 inches, an elegant curve in this greatly enhances the beauty.

A *funicea* is of erect habit, unbranched, and attains a height of 3 feet. Stem at the base half-an-inch in diameter, tapering towards the top. Leaves, 7 to 8 inches long, opposite elliptic-lanceolate, with an entire margin; they are of a very soft dark green velvet above. The veins are very prominent beneath, and correspondingly impressed on the upper surface. Towards the inflorescence the leaves decrease in size, and gradually from their great colour change into an intense red, producing a marvellous contrast to the dark green foliage, and rendering the plant invaluable for table-decoration. The bracts last in perfection fully two months. The flowers develop from the axils of the bracts; they consist of a red calyx and a tubular corolla about an inch long, and of a creamy-white. The plant requires stove treatment and frequent syringings, as it is liable to red-spider and other insects pests. Propagation is somewhat slow, but I found it to strike in almost any light soil if sufficient heat is given. To obtain good cuttings, the plants should be cut down after flowering, leaving a few healthy leaves. A compost of loam, peat, and sand would suit it well; and when the bracts begin to develop a little liquid-manure should be given. During a stay of some years in England, I never remarked a plant. *Erich B. Behnick, Berlin*. [It is well known here. Ed.]

NOTES ON THE NARCISSEUS.

(Continued from p. 126.)

OUTDOOR CULTIVATION: SOILS.—The *Narcissus* is an accommodating plant, and we seldom hear of its absolute failure in any locality, though it is now widely grown by both professional and amateur gardeners throughout England, Scotland, and Ireland. Pasturals, heavy, ill-drained clays, and very dry sands present adverse but not insuperable conditions, while the alluvial deposits known as warp, wash, drift, &c., are the ideal *Daffodil* soils. The very finest English-grown flowers of which I have had knowledge, come from Caister, near Great Yarmouth, where the alluvium brought down to the coast by the Norfolk and Suffolk rivers is 20 feet deep or more, always moist without being water-logged, and full of plant-foods, which can be brought up *ad libitum* to replenish the upper spits. Here, that most difficult subject, *N. cerneus* fl. pl. increases readily, and *poeticus* *poetarum*, another test-plant, which will scarcely grow on poor, dry soils, almost equals *Empress* in vigour and size of bulb. Magnificent flowers are also grown at Chilwell, in the silt of the Trent valley, and the market-garden settlements in the Thames Valley, fill Covent Garden with excellent *Daffodils*. The next best soils are sandy loams resting on moist rock. I have in mind a sheltered garden of this character, near Horsham in Sussex, where the white trumpets, and, *à fortiori*, all other *Daffodils*, are entirely happy. Stiff clays can be much ameliorated, in the case of amateurs who have manageable areas to deal with, by the incorporation of road-grit, leaf-mould, and especially charred earth and bonfire stuff. Drought is the worst enemy of the *Narcissus*, and the most hopeless to combat. The perfection reached

by *Daffodils* in the south of Ireland and the Scilly Islands is due not only to excellent soils but to abundant atmospheric moisture. The lack of this on the upland country between Hants and Wilts, where the average yearly rainfall is very light, constitutes my own chief difficulty, and my chief desideratum is always a wet February and March.

MANURING.—The common assertion that *Daffodils* resent manure is true only in a very limited sense. Crude stable-manure in actual contact with the bulbs, especially on retentive soils, is certainly injurious; but an analysis of the *Narcissus* plant shows that it needs large supplies of phosphates and potash, and must receive these from without if not abundantly present in the soil. It is the store of these constituents, to a not readily exhaustible depth, in alluvium, that renders it the best staple for the *Narcissus*. Nevertheless, the large market-growers of cut blooms in the Thames Valley give their already excellent ground an enormous annual supplement of London stable-manure. Probably the absolutely best routine for all but the more delicate *Narcissi* is to let a nitrogen-loving crop first occupy a freshly-manned plot; the succeeding plantation of *Daffodils* will find ample food in the residue. My own custom is to manure and crop a plot with early Potatoes every year; this leaves the ground in the best condition of heart and tilth, and vacant at the right season for planting the bulbs. Where I am forced to grow *Daffodils* year after year on the same ground, I top-dress the beds in January or February with pure dissolved bones at the rate of 1½ oz. to the square yard. The same quantity of raw bone meal, dug in at the time of planting, is of service if the ground seems poor. On very sandy soils a small quantity of kaolin, or potash in some form, may be added. Charred earth and bonfire ashes also supply potash, and may quite safely be largely dug into beds containing sickly *Narcissi* or delicate varieties. These remarks refer, of course, to bulbs planted in their own separate quarters; clumps among herbaceous plants can only share in the top-dressing which the borders may receive; but if within the reach of hungry roots, they should occasionally be helped by a little artificial manure from the surface. The white Trumpets, *pallidus precox*, and most of the imported wild Trumpets, thrive best in beds of pure loam and leaf-mould, free from stable manure, or in grass. It is noticeable that *N. poeticus* and its hybrids (*N. incomparabilis*, &c.), will assimilate more nitrogen than the Trumpet *Daffodils*, not excepting even the most robust of the latter.

PLANT.—The opinion has been advanced of late that *Daffodils* prefer a shaded situation. This is not generally true, and, if it were, would be unfortunate for the large market-growers, who must necessarily grow them in large breadths in the open field. As wild plants, *N. pseudo-Narcissus*, in nearly all its varieties, and *N. poeticus*, are found on mountain pastures in the fullest exposure to air and sun, and nearly all our garden *Daffodils* fall under the head of these two species and their hybrids. *Pallidus precox* is said to grow best in shady thickets, and *N. triandrus* to prefer a northerly aspect. With these, and possibly a very few other exceptions, for the production of fine and abundant flowers, there can scarcely be too much sun where there is no lack of root-moisture. And hard, well-ripened, floriferous bulbs cannot be obtained by less than the whole of the sunlight which our climate affords. Rows of fruit-trees give a wind-break in bleak districts, and their slight shade may check evaporation in a hot, dry spring, but they should be far enough away for their roots not to starve the bulbs. *Daffodils* with much red colouring in the corona are speedily bleached under full sun; but to enjoy the beauty of such kinds they should be cut in bud, and expanded in water. The double white *poeticus* presents a difficulty, as it produces a large percentage of blind scapes unless supplied with abundant moisture in air and at root during its whole time of active growth. It is rarely at home only in cool districts with heavy annual rainfall, or elsewhere only in wet seasons, and I have proved that planting it in shade results only in much leaf and scanty bloom. *G. H. English, hort.*

Return.—P. 123, for *amicus*, read *cerneus*

PICEA OMORICA (THE SERVIAN SPRUCE).

This, the latest discovered of the European Spruces, was figured in the *Gardeners' Chronicle* for March 8, 1884, p. 309, but at that time it had not been introduced into this country. Even now specimens, except

of small size, are rare, but this need not be the case much longer, for the species is now in commerce. There is a group of trees in the pinetum at Kew which were raised from seed sent from Belgrade eight or ten years ago, and which are now large enough to give some indication of its probable value in gardens. It may at once be said that few of the

Spruces thrive in the indifferent soil and atmosphere at Kew so well as this one promises to do. The trees are now 6 to 8 feet high, of symmetrical outline, and well furnished with foliage to the ground. The leading shoots made in 1896 are from 12 to 18 inches long, so it is evidently a rapidly growing plant. The leaves are about three quarters of an inch long, not so distinctly four sided as most of the Spruces, and they have two glaucous lines on the upper side—that is, the side towards the growing point of the shoot. The wood is furnished with short, black hairs. The species is a native of the mountains of Servia, Bosnia, and Montenegro, and its existence was first made known to science by Dr. Panice, who described it as equalling any of the European Spruces in stature. When it was first discovered it was thought by some authorities to be merely a form of *P. orientalis*. It may bear some resemblance to that species when very young, its leaves being then much smaller, but plants of the size of those at Kew are unmistakably distinct. *P. ajaensis* appears to be its nearest ally. *W. J. B.*

Fig. 14.—*PICEA OMORICA*, THE SERVIAN SPRUCE.
(Natural size, from a photograph.)

THE BULB GARDEN.

THE CULTIVATION OF DAFFODILS IN POTS.

IN my note on this subject in the *Gardeners' Chronicle* for February 13, p. 105, I appear to recommend the typical *Narcissus poeticus* as adapted for forcing, whereas it is, of all *Narcissus*, the least suited to the purpose. Indeed, it may with truth be stated that the old pleasant-eye *Narcissus* abhors artificial heat, and when perchance a stray bulb finds its way into another ha'ch this is clearly shown. The same remark applies also to the true Lent Lily, *N. pseudo-narcissus*, and to the twin flowered *N. biflorus*. Of the latter I had for a year or two a few bulbs mixed with one of the larger lots, yet, notwithstanding they possessed plenty of roots prior to being forced, they were uninfluenced by heat, and when early in March the other kinds were tured out again, this one, *N. biflorus*, would be only just on the move, and generally would flower scarcely a day earlier than the bulbs which had remained in the open ground throughout the winter. The reason why some species thus refuse to grow and flower when forced I do not know. *J.*

KEW NOTES.

SAXIFRAGA APICULATA.—Some fine tufts of this early crested species are now beginning their season of flowering at Kew, inasmuch as large examples are prone to a long continued season of bloom. This species, which has numerous synonyms, some of which are erroneous, is one of the best, as well as the freest flowering among the earliest flowering species. It is a free grower, and with care may soon be grown into handsome tufts 1 foot or more in diameter. The plant can be increased by pulling it carefully to pieces, and re-planting these pieces somewhat deeper than previously in a fairly moist spot in sandy soil. Most of these will strike root. The idea that *Saxifragas* prefer a very dry position has no foundation in fact, and many plants are lost when so planted; whilst others are lost after dividing the tufts by being planted insufficiently firm and deep. The flowers of *S. apiculata* are of clear primrose-yellow, and they appear in great profusion throughout the spring.

ADONIS AMURENSIS.

Plants of this new and interesting species are to be seen at the present time in flower, the finest growing in a somewhat protected nook in the rock garden, and further screened from rough weather by a piece of glass being put over them. It is a native of Mandshuria, and, judging by the specimens now in flower, promises to surpass the few known members of the genus. The flowers are of a golden-yellow tint, and situated at the summit of the erect growths. The latter are vigorous, whilst as yet they are not fully developed. It is among the earliest February flower-

ing plants, the first blossoms appearing early in the month, and much before the well-known *Adonis vernalis*. It is probable that *A. amurensis* will succeed in a deep, light, sandy loam, its cultivation giving but little trouble; in stiff clay soils, on the contrary, the plant never appears to be quite a success.

SNOWDROPS

abound in all parts of the grounds as groups and colonies, imparting very pretty effects. But it is in the rockery garden that the choicer species find a place. Here were remarked *Galanthus Alleni*, in vigorous examples; *G. Ikarie*, with broad, handsome, and slightly recurving leaves, and short and sturdy flowers. This fine species is being established in quantity in the upper parts of the rock garden, and another year it will be seen in increased vigour. Others consist of *G. Elwesii*, *latifolius*, *imperati*, and *caucasicus*. *J.*

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Easton Castle, Leicestershire.

The Early Peach-house.—The fruit on the trees in this house, now swelling fast, should be thinned for the last time, removing, if the set is a good one, the deformed, and those hanging in positions where they will not come of good colour. If first-class fruits are looked for, one fruit to one square foot of superficial area, and one fruit on a shoot should be left; although, when the set has been light, I have often left two fruits, which have swelled up all right—still, it is not a practice to recommend in general. It is also essential to the attaining of high colour in the fruits to elevate each by means of a short piece of lath inserted between the branches on either side, thereby enabling the fruit to get all the sunlight possible. As the trees will now begin to feel more severely the calls made on their energies, manurial aids will be valuable, and I know of nothing that is so beneficial at this stage than fish manure sprinkled on the borders, and carried down to the roots by a good application of warm water. The only fault to be found with this sort of manure is its unpleasant odour, but this passes off in a few days. Keep the syringe well at work to prevent red spider getting a foothold, and to clear away aphids. If this be done, and excessive heat in the pipes avoided, these, the greatest enemies of Peach-trees, may be certainly kept greatly in check. Avoid crowding the trees with more young shoots than are required, and stop, at the first leaf on the base, all lateral shoots not required as bearing shoots another year.

Succession Peach-houses.—These trees which were started at the New Year having set their blossom, will now require to be disbudded. If aphids are noticed, fumigate the trees without the least delay, eradication being easier now than when the leaves become curled, affording two light fumigations in preference to one that is heavy. In disbudding, take the superfluous top and bottom shoots first, leaving the lowest shoot at the side of the bearing shoot of this year for next year's fruiting; and, instead of removing most of the shoots entirely, and thereby giving the trees a check, pinch out the points of some of them, thus leaving two or three leaves on each to help furnish the tree with foliage, and as the shoots intend to remain green, these pinched shoots may be altogether removed, but leaving them where there are fruits, so that they may attract sap to the fruits. As soon as ever a shoot is long enough to be tied to the trellis, all those which are to furnish the tree should be tied or "heeled-in" at the base. Any extra strong shoots should have the points nipped out. Avoid draughts, the air in March being often keen and cold, although the sun may be shining. Alkaling air in large amount is often the cause of mildew appearing. As the sun continues to increase in power watch the temperature carefully, and do not allow it to rise above 55° at any time, this being, in my opinion, one of the causes of fruit dropping.

The Later Peach-houses.—Peach-trees now in flower require to be kept rather dry as regards the air of the house, but it must not be still air; and do not let the houses get arid, but sprinkle the paths and borders twice or thrice daily in very fine weather. Artificial fertilisation is not so imperative as earlier in the year, but it is an assistance to the large-flowered

varieties if pollen from the small-flowered varieties be applied to them by means of a camel-hair pencil. The latest house of all should be kept as cold as possible, and in spite of so doing, I fear the mild weather will cause the trees to start into growth. Keep windows and doors wide open day and night, unless sharp frosts or very cold winds should occur, and the flowers have begun to open.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Bedford, Dorking.

Acridies.—During the next few months the Orchid-grower will be extremely busy in consequence of the potting, watering, damping-down, shading, and attention to ventilation, which will be necessary. At the present time many species are sufficiently advanced in growth or root-activity to admit of being repotted or top-dressed. Such East Indian-house plants as *Acridies* and *Scaccolabium* show by their roots turning green at the points that they have commenced to grow. These tender roots grow rapidly, and are easily injured, and no time should be lost in effecting what is needful to unsatisfactory plants. Any specimens that have lost a number of their lowermost leaves, and show much bare stem, should be carefully turned out of their pots, then cut off so much of the base of the stem that when the plant is transferred to the new pot the basal leaves will be just above or on a level with the rim. Fill in around the stem with clean crocks to about one-half the depth of the pot, and re-plant as many of the old roots as possible, working in amongst them equal parts of fresh sphagnum moss and crocks up to the rim of the pot, and afterwards living moss well up to the base of the leaves. Plants that are healthy require to have the old moss carefully picked out, and to be re-surfaced with the same in a fresh living state. Shade the disturbed plants from strong sunshine, and afford one thorough watering, which will enable us to keep the roots inside the pot moist for a considerable length of time. In a few days, when the sphagnum-moss on the surface appears dry, give only a slight sprinkling of water, sufficient to keep the moss growing. Pinch off any flower-spikes that may appear on those plants that have recently been repotted, and wait until the plants have become re-established before allowing them to bloom. All of the following *Acridies* are well worth growing:—*A. Lawrencei*, *A. L. v. Sanderiana*, *A. Lindleyana*, *A. Lobbi*, *A. Houlettiana*, *A. Godfreyi*, *A. Fildingsi*, *A. expansum*, *A. falcatum*, *A. affine*, *A. Larpentei*, *A. odoratum*, *A. subvittatum*, *A. quinquevittatum*, *A. virens*, *A. crispum*, *A. crassifolium*, and *A. araguanum*. The terete-leaved *A. vaudanum* (*cylindeum*), a singular species, is now showing its flower-spikes, and must not be disturbed at the root. Unlike the other species, it thrives best when fastened to upright teak rods, to which the small aerial roots cling tenaciously. During the growing season syringe the plant overhead several times a day, and afford similar treatment to *A. rotundifolium* and *Sarcotanthus filiformis*. The dwarf-growing and sweetly-scented *Acridies japonicum*, from the hilly districts in Japan, should be grown in shallow teakwood baskets. The intermediate-house is the best place for it in winter, and in summer it may be removed to the warmest end of the cool house.

Scaccolabium.—Such species as *S. Blumei*, *S. retatum*, *S. promorsum*, *S. colutei*, *S. spectiosum*, *S. rhabdanthum*, *S. giganteum*, and the dwarf-growing *S. ampullaceum*, *S. sinuatum*, and *S. curvifolium* should be suspended in baskets near to the roof in the hottest part of the house during their season of growth. The small-growing *S. Hendersonianum* is a little gem, and has spikes with bright rose-coloured flowers. It should be suspended to the roof in small pans or baskets, and requires little shade at any time.

Angraecum and Vandae.—The winter-flowering variety of *Angraecum sesquipedale* is now commencing to emit new roots, and, if required, it should be repotted or top-dressed, as recommended for *Acridies*. The spring-flowering variety should not be disturbed until after the flowers fade. The "fish bone" *Angraecum pertusum*, which is now in bloom, should be treated similarly. *Vanda Cochinchinensis*, which is also in bloom, will be luxuriantly if placed in the exterior of a long teak rod cylinder, and placed in the highest temperature available. It requires an abundance of moisture at all times. *Vanda Anacensis* and *V. Kimballiana* have already commenced to grow, and if more root space is needed it should be given them at once. Upright teak cylinders or baskets are preferable to pots, as they allow plenty of air to circulate among the roots. Sphagnum-moss, with a few pieces

of crock intermixed with it, are all that is necessary for them to root in. Select the lightest and most airy position available in the intermediate-house, choosing a spot distant from the hot-water pipes. Abundance of water is necessary throughout the growing season.

Other Species.—Immediately such species as *Spathoglottis Regneri*, *S. Fortunei*, *S. Lobbi*, *S. Griesonii*, *S. Kimballiana*, *S. aerea*, and *S. angustatum*, commence to grow they should be repotted, using a mixture of peat, chopped sphagnum-moss, and coarse silver-sand, with plenty of drainage material. The same remarks apply also to *Microstylis bella*, *M. Scotti*, *M. macrodolia*, and to *Ipsaea speciosa*. Place them in a shady corner of the East Indian-house, and afford copious waterings until growth is completed.

Shading.—Recently we have found it necessary on several occasions to shade the cool-houses, and to put temporary shading over *Bolles*, *Cypripedium*, *Phalaenopsis*, *Angraecum*, and young tender seedlings just starting to grow, and many other tender plants. Orchid-growers cannot be too careful as regards shading, and especially is this the case after the comparatively new seedlings, and after winter now passed; therefore, have all blinds and shadings put in order without delay.

PLANTS UNDER GLASS.

By G. H. MAYCOCK, Gardener, Luton Hoop, Luton.

Winter-flowering Carnations.—Cuttings propagated as previously advised will now require to be potted; 3-inch pots are the best for the purpose, and a mixture of three parts good loam which has been previously stacked in a dry shed, one of charred loam, and one of sand will suit them well. Replace the plants when potted in a warm frame, and keep them there till well rooted, and afterwards a cooler temperature will suit them. Some growers prefer to syringe the plants, and others do not. It is a question of locality, and in all cases the grower must determine for himself whether the practice is desirable or not.

Euphorbia jacquiniiflora.—A good batch of plants may now be started to furnish the first supply of blooms. With careful management flowers of this *Euphorbia* may be had all through the winter months. They require a longer season of growth than *Euphorbia (Poinsettia) pulcherrima*. To have good blooms from them after the bulk of the *Chrysanthemums* are over until the end of February or commencement of March, three batches should be obtained, and propagated at intervals of a month. Cuttings readily root if taken off with a heel when about an inch long; or a stock may be acquired by cutting up pieces of the old stems, in lengths of about 12 inch long—place these in shallow pans in an upright position, using a compost of half leaf-mould and half sand, and remove them to the propagating-house. When three batches are required, the operator should take off a third of the stem each time, the lower buds will then be more matured when the next batch is required. Keep the old plants quite dry at present, but in May they might be started to help furnish a late supply of bloom.

Roses.—The best time to prune *Roses* growing in a house set apart for their cultivation is the month of November, at which season exhausted soil should be cleared away, and fresh substituted for it. Assuming that this has been done, and the plants are advanced in growth, a thorough watering of the borders, followed by a mulching of rich farmyard-manure, will be of great assistance to them. In order to keep aphides in check, the house should be fumigated occasionally. A suitable temperature at this date is 50° by night, and 55° by day, affording air when the weather is mild and open, but avoiding cold draughts, and giving air in frosty weather.

Fuchsias.—Large, old plants, which were pruned last month, should be shaken out of the old soil, and re-potted in a mixture consisting of loam three-quarters, and leaf-mould one-quarter, used in a fairly coarse state. A single specimen *Fuchsia* are very effective for conservatory decoration. The *Fuchsia* is easily propagated, by taking shoots 3 inches long, and plunging in a gentle bottom heat in a frame, and as soon as rooted, potting them, and growing them in warmth till May or June. With care, spring-struck *Fuchsias* will make nice plants of good size in the autumn.

Erica hyemalis and **Eparis.**—Any plants which are passing out of flower should have the current year's shoots pruned hard back, and be kept cool in a quiet, and slightly drier than before. When the young shoots are about 1 inch long, the re-potting of

these plants which need it should be done, and the drainage of every one should be put in good order. The pots used should be well baked and hard, and be very efficiently crooked, a large quantity of small, nicely-broken crocks being placed over the large ones at the bottom of the pots, and above these, pieces of the size of Hazel-nuts. The potting-soil should consist of hard peat and sand, and the potting must be very firmly done. During the summer months place the plants in cold frames, a slight shading being afforded them during the hottest part of the day. The plants require to be afforded water with much judgment, being very sensitive to extremes of either wetness or dryness.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Droppore, Maidenhead.

Gladiolus.—With a view to obtaining early flower spikes either for cutting or outside decoration, some of the hardiest varieties, as G. Breche-decay may be planted as soon as the soil is in a condition for working upon. The early flowering G. Colvillei and Colvillei alba (The Bride) should be planted in February or early in March. Another plan is to pot them up early, placing about five corms in large 60-sized pots, and place in a cold-frame, or under cocoa-fibre refuse outside until rooted, when they may be taken out of the pots and planted into the borders.

Border Chrysanthemums.—These varieties of the Chrysanthemum flower from late summer to the end of the month of October, and are effective plants wherever singly or in small groups. Space should also be found for a small collection of them in the reserve garden for cutting purposes, the flowers being especially useful in the autumn. Those gardeners who have to furnish large quantities of flowers for sending long distances at that season will find them extremely valuable. Improved varieties have been introduced during recent years in considerable numbers, and fairly good blooms of the Japanese section may be cut in the months of September and October, and if sown in all of the plants can be afforded some slight protection, good flowers may be obtained to the end of the latter month, and sometimes still later in the year. Early spring is a suitable time to propagate these early-flowering varieties, and the mild weather of the past few weeks has caused numerous strong shoots, suitable to make cuttings, to start from the plants in the borders. These shoots, with or without a heel, if stripped of their lower leaves, should be put, to the number of four, round the sides of large 60-pots, filled with a light sandy soil, a small quantity of rough leaf-mould in the bottom being sufficient drainage for the pots. If the cuttings are to be placed in a frame having a mild bottom-heat, and preserved from damping off by affording air daily for a short time, the cuttings will root in about three weeks. If large plants are required, they may be repotted into 6-inch pots when well rooted without disturbing them. Whether parted or not, the plants should be kept rather close in a cold-frame for a short time after being repotted or potted-off. If topped once and gradually hardened off, these young plants will be ready to plant out at the end of the month of April. A very floriferous variety is the Pompon Flora, a flower of a deep yellow colour. This variety has the merit of commencing to flower in August, and continuing in bloom more or less until cut down by severe frost. Some other early Pompon varieties are Torador, bronzy-red, 1½ foot; Canari, pale yellow, 1½ foot; Jacintha, pink, 2 feet; Præcitéc, ruby-red, 2 feet; Frédéric Marquet, bronzy-red, 2 feet; Strathmeath, rosy-pink, 2 feet; Mrs. Cullingford, white, 2 feet; M. W. Piercy, orange red, 2½ feet. Of small Japanese varieties flowering principally in September and October, the following are desirable varieties:—Madame G. Desrange and the yellow sport Mrs. Hawkins; Carrie Denny, amber; Harvest Home, bronzy-red, 3 feet; M. Gustave Granwehr, white, 2 feet; Goldmine, golden-bronze, 2 feet; Roi des Prêceces, rich dark crimson, 2 feet; Rycroft Glory, golden-yellow, 3 feet. The old hybrid Pompon, Scur Mélanie, when planted in a sheltered position is an extremely useful October flowering variety, and the pure white flowers keep fresh in a cut state for a considerable time.

Carnations.—If the plants of the border Carnations have been wintered in cold pits or frames, preparation should now be made for transferring the plants to beds and borders. All plots to be occupied by Carnations, which also includes Picotees, should be

deeply dug, having previously dressed it with well-rotted manure. Some of the manure should be kept within 4 inches of the surface, and to ensure this being done bastard trenching is advisable. I prefer to layer Carnations early, and transplant direct to the borders in the autumn which is undoubtedly the better method where the soil of the garden is moderately light, and local conditions are not against the well-being of the plants in the winter. In heavy soils, and in gardens that are low and are very damp, it may also be necessary to put the plants under glass during the winter. Glass protection is, however, not without its disadvantages, the plants, in my experience, being then more susceptible to the dreaded "spot" on the leaves, unless the air of the frames can be kept artificially dry during mid-winter. The plants in the beds should be examined, and those which are loosened by frost pressed firmly down, and the soil, when workable, stirred with a Dutch hoe. Seeding Marguerite Carnations should be kept near the glass in a house or pit having a warmth of 45° to 50°. If seed was sown when sown, the seedlings will be ready at this date for pricking-off into other boxes at about 2 inches.

Lobelia cardinalis in store boxes, if the stock is insufficient, may be pulled apart, all those pieces which possess two short roots and some roots put in small 4½s, using a soil consisting of half leaf-mould and half peat, with a small quantity of sand. Stand the divided and undivided plants, which should also be potted, in a warm house till established, then remove to cooler quarters.

Calceolarias, Pentstemons, and Gazanias, which were struck in the autumn, and have been wintered in cold frames, ought now to have full exposure, excepting when frost prevails; pinching the points of the leading shoots to induce bushiness.

Hints on Work in General.—Gravel paths will have been loosened by frost, and will be the better for a good rolling when dry on the surface. The re-gravelling of dirty paths should be finished off within the next two or three weeks. Box edgings may now be lifted and relaid or mended; and if the walks require gravelling, the edgings should first be relaid. Lawns should be swept, and moss, plantain, and weeds generally raked off or spudded out, and the holes caused by the extraction of the roots filled with bany soil. A surface dressing of fine soil, wood-ashes, and soot, in mixture, if applied at this season, will encourage the growth of the finer grasses and Clovers, to the exclusion of moss and weeds generally.

THE KITCHEN GARDEN.

By W. DUFF, Gardener, Highclere Castle, Newbury.

Khubarb.—In planting new Rhubarb-beds, as the crowding this season are already on the move, no delay should occur. The land should have been heavily manured and deeply trenched early in the winter. Lift as many old roots as are likely to be wanted, dividing them into separate crowns with a sharp spade, the strongest being then selected and planted to rows 3 or 4 feet apart each way, not quite burying the crowns. If seedlings are planted, only those of the most promising colour and size should be selected, and in any case many of the plants are sure to prove worthless.

Turnips.—A small sowing may now be made, preferably on a border with an eastern aspect. In sowing this early the plants will probably root to seed before the roots attain to their full size, and that only a small breadth need be sown, sowings being repeated every ten or fourteen days. Sow the seeds, if fresh, and of good vegetative power, thinly in drills, 15 to 18 inches apart, applying, if possible, a good dressing of wood-ashes at the same time; and as a protection from the attacks of small birds, wet the seeds, and roll them in redlead powder. The best Turnip for early work is Early Milan; still, it will be prudent to sow a pinch of Snowball or Early Swedes, which, coming into use a week later, avoids the chance of there being a break in the supply of roots.

Peas.—For affording Peas in the month of July, seed should now be sown in quantity. In some soils where the soil is dry and shallow it may be advisable to make trenches 15 inches apart, and to place a thick layer of rich manure on the bottom of each, and treading it firmly, then returning a portion of the soil, and sowing the seed and covering it with 2 inches of soil. The soil that remains will come in for earthing-up the plants. On good land of a retentive nature, trenches are not

necessary for Peas. Tall varieties must be allowed a space of from 5 to 6 feet between the rows, but a better method is to sow in rows 12 feet apart, and crop between with Turnips, *Califlovera*, *Salading*, &c. As soon as the early sowings show above the ground, dust the latter frequently with fresh soot or quick-lime as a means of warding off slugs, &c.; earthing-up and staking the plants as soon as they are a few inches high. Keep a sharp outlook for the sparrows which pick off the tops, protecting accordingly. Peas raised under glass must be kept cool and be properly hardened off before being planted on a warm border. When planting these house-raised Peas, it is the best course to stake them forthwith, and afford some kind of protection on the more exposed side of each row.

Miscellaneous Sowings.—Seed for furnishing the main crop of Brussels Sprouts may be sown now in a border that is sheltered from harsh winds. This sowing, if not quite so early as that sown under glass, will probably give a better return. If large Sprouts are liked, choose the Aighburth or Serynger's Giant, and for small solid Sprouts nothing is better than May's Northrup Prize, or Sutton's Dwarf Gem, the latter with dwarf stumpy habit of growth. Sow seeds of some good early Cabbage, as Flower of Spring, or Ellan's Early, and a pinch of early and late Cauliflower, all of which are better for being sown in drills 9 inches to 1 foot apart. The first sowing of Ralishes may be made on a warm border, sowing the seeds broadcast, and covering them with less than half-an-inch of fine soil. Wood's Early Frame for long roots is a good Radish, as is French Breakfast, if short ones are preferred.

THE HARDY FRUIT GARDEN.

By H. W. WARD, Rayleigh, Essex.

Recently-Planted Trees and Bushes.—In places where the condition of the soil has been so wet as to prevent its being made firm about the roots and stems of transplanted fruit trees and bushes, no time should be lost in treading it pretty firmly over the roots and around the stems when the ground is in a workable condition. Stakes used as supports to staked trees should be taken upright, and the soil left firm about them at the same time. Afterwards point the soil thus trodden over slightly with a digging-fork, and apply a 2-inch surface-dressing of short turf. In the case of light, shallow land occupying a somewhat high and consequently dry situation in which fruit trees and bushes have been planted, the loosened soil after a short period of dry weather soon becomes too dry for healthy root-action. Consequently water should be given at the roots, or the growth made will be stunted and unfruitful.

The Training of Pear and Plum Trees on walls having an easterly aspect, as well as Peach and Nectarine trees occupying a like position, should be completed as soon as possible. There can be no doubt that the lack of sufficient moisture in the soil is frequently the primary cause of the stunted appearance and premature decay of many neglected wall-trees. Everything is against wall-trees obtaining naturally sufficient moisture at the roots at any time throughout the year. In addition to the extra drainage which the foundations of the walls afford, the latter prevent the rains—even during a wet season—from penetrating more than a couple of inches deep into the soil over the roots. In the case of a downpour even—rain coming straight down from the clouds—the sloping surface of the borders carries most of the water some feet away from the foot of a wall. Any reader may prove this by digging out the soil to the depth of 7 or 8 inches at 1 or 2 feet from the stems of trees trained against south, east, and west walls at any time in the year. Hence it is that during the greater part of the last quarter of a century I have had the surface of the soil above the roots of my Peach, Nectarine, Apricot, Plum, and Cherry trees pricked over with a fintined fork in spring, before the trees had pushed into flower, following this with a surface-dressing of half-rotted manure, and a good soaking of clear water, the watering being repeated as soon as the fruits were set, and several times afterwards until the crop ripened. Sometimes I have found the first tub of 36 gallons of water insufficient to moisten the soil down to the roots of a Peach or an Apricot tree just before the flowers had begun to open, and so had to repeat the application. This water should receive attention forthwith.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER. Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	MAR. 7	Annual meeting of the United Horticultural Benevolent Provident Society, at Caledonian Hotel, Adolph.
TUESDAY,	MAR. 8	
WEDNESDAY,	MAR. 10	Royal Horticultural Societies Committees.
WEDNESDAY,	MAR. 10	North Essex Gardeners meet.
SATURDAY,	MAR. 12	Royal Botanical Society meet.

SALES.

MONDAY,	MAR. 8	Greenhouse Plants, Roses, Herbaceous Plants, Lilies, &c., at Protheroe & Morris' Rooms. Collection of Border Plants, Roses, Struchs, Lilies, &c., at Stevens' Rooms.
TUESDAY,	MAR. 9	Camellias, Gladioli, Carnations, Anemones, &c.; Imported and Established Orchids, at Protheroe & Morris' Rooms. Japanese Lilies, Continental Plants, Tuberoses, Spinees, Gladioli, and Palm Seeds, at Protheroe & Morris' Rooms.
WEDNESDAY,	MAR. 10	2500 English, German, and Dutch Roses; Fruit Trees, Border Plants, Struchs, from Holland, Bulbs, &c., at Stevens' Rooms.
THURSDAY,	MAR. 11	Special Sale of Border Plants, Struchs, &c.; also 2000 Japanese Lilies for the Trade, &c., at Stevens' Rooms.
FRIDAY,	MAR. 12	Orchids from a Messrs. F. Sander & Co., at Protheroe & Morris' Rooms. Photographs and Scientific Apparatus, at Stevens' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick—41° 8'.

ACTUAL TEMPERATURES:—

LONDON: March 31, MAX., 49°; MIN., 37°.
PROVINCIALS:—MILGROVE (6 P.M.): MAX., 44°, DEVON COAST: MIN., 35°, SUNDURGH: MAX., 41°.

A GOOD deal of unnecessary heat has been evolved lately over a simple matter about which some people appear to hold rather lax views, as to the fairness, or otherwise, of competing with the same varieties of fruit in both the dessert, and the culinary, or "kitchen" classes; for example, with such popular varieties as Blenheim Pippin Apple, Bourré Diel Pear, and Victoria Plum. According to our best authority, Blenheim Pippin is highly esteemed, "either for the dessert or culinary purposes;" Bourré Diel is distinctly termed "a dessert Pear of the highest merit;" and Victoria is as distinctly stated to be "a culinary Plum;" yet probably these three varieties are employed more frequently than any others as competing dishes of fruit in both the dessert and the culinary classes. Is it necessary for competitive purposes to have two classes—(1), Dessert; (2), Culinary—of Apples, Pears, and Plums? Most people of any experience will reply in the affirmative; and it is one of the points in horticultural competitions upon which the public look to the Royal Horticultural Society for instruction, and a definite law or rule to guide them. For all that has been said to the contrary, the point is not a difficult one, and a small committee of level-headed experts would quickly settle it in such a manner as to meet the approval of all reasonable people.

The distinction between (1) "dessert," and (2) "culinary," varieties, is only needful for competitive purposes, and it is not necessary to frame a law to meet any other purpose. Gardeners, amateur fruit growers, cooks, and all others interested in the uses of fruit, can determine for themselves how they will use the different varieties of Apples, &c.—in a raw, cooked, or liquid state—according to their tastes, and the purposes they want to serve. That side of the question may be safely left to them by the managers of fruit shows and competitions.

What is required by managers, as well as by competitors, at fruit shows, is a definite list of the varieties of Apples, Pears, and Plums, which shall be classed, for competitive purposes only, as Dessert varieties, or as Culinary varieties. The Royal Horticultural Society has already gone some distance in the right direction in compiling the list of Apples and Pears, for the guidance of exhibitors and others, at the Crystal Palace Fruit Show of the Society, and all that is necessary is the extension of the lists, until they comprise all the Apples, Pears, and Plums usually exhibited under ordinary circumstances. Having taken the trouble to glance through the latest edition of Dr. Hogg's *Fruit Manual*, our chief authority on the classification of Fruits, and particularly of Apples, it may be of interest to show, from the following analysis, how comparatively little remains to be done by the experts of the Royal Horticultural Society to settle which varieties of Apples, Pears, and Plums shall be classed as "dessert" and "culinary." Dr. Hogg describes rather over 700 varieties of Apples, and classifies about 270 as "dessert," 250 as "culinary," 80 as "dessert and culinary," 75 as "cider," and only about 45 are not referred to any class.

Of the eighty or so varieties of Apples classed as "dessert" and "culinary" by Dr. Hogg, a tenth are already dealt with in the lists of "dessert" and "cooking" varieties, compiled by the Royal Horticultural Society, including such varieties as Blenheim Pippin, or "Orange," Duchess of Oldenburg, Emperor Alexander, and Peasgood's Nonsuch, which are all placed in the list of "cooking Apples," Allen's Everlasting, Brownlee's Russet, Fearn's Pippin, and Worcester Pearmain being placed in the "Dessert" Apple list. Such an excellent example for competitive purposes should be carefully followed out, and the remaining popular varieties of Apples, classed by Dr. Hogg as dessert and culinary, put into one or other of the two classes. There should be no difficulty in dealing equitably with such well-known varieties as Golden Pearmain, Gravenstein, Reinette du Canada, and such-like, classed by Dr. Hogg as dessert and culinary.

In classifying the Pears, Dr. Hogg has not been so exact, as he passes about 110 out of about 650 varieties described without any reference to their "dessert" or "culinary" qualities; but with Pears the classification may not be considered so needful for general purposes, although it is imperative for competition. It does, however, class about 170 varieties as "dessert," and undoubtedly most of the varieties not classed are also "dessert;" thirty-two as "culinary" or stewing; and thirty as "perry" Pears.

Out of about 186 Plums described by Dr. Hogg, eighty-four are classed as "dessert;" sixty-four as "culinary;" and only thirty-eight, mostly never seen in competition, are not classed.

It is thus seen that if Dr. Hogg's *Fruit*

Manual, and no better work can be found, is taken as a basis for the classification of Apples, Pears, and Plums into (1) dessert and (2) culinary varieties, the work of classifying them need not be either costly or prolonged; and the authorised lists compiled and published by the Royal Horticultural Society would be a valuable boon to all concerned in the management of fruit shows and fair competition.

This popular provincial Society, one of the best-known and most largely patronised in the South of England, now finds itself, after nearly thirty years of active operations, to be in danger of collapse, because it has at present no place in which to hold its exhibitions. Formerly it found ample room for its fine annual shows in Fitzgirth Park, close to the town; but eventually the builder ejected them, and a home was secured and maintained at great expense, in Westwood Park, a little further out. That was held on a lease that unfortunately expired last year, and thus the Society finds itself literally without a place in which, at the customary period of the year, it can hold its meeting. Just on the north side of the town is the well-known and beautiful common, some 300 acres in extent, which is in no sense a public park, but which is none the less under the absolute control of the local corporation. For the privilege of boarding in a few acres of this large space, so that the annual show may by then held in August next, the Society has asked permission. That body quotes the fact, that in some other towns, notably at Shrewsbury, similar privileges are granted; and more than once have some of the large peripatetic agricultural societies had the same privilege granted them on Southampton Common, and no one has been injured. These, too, have had some 30 acres enclosed for many weeks, whilst the Society asks for but a few acres, to be enclosed for only a few days. No doubt the corporation fears that applications of this nature may become too frequent, if once the first be granted; but it would be an immense misfortune had the Society no place to hold its shows. Such are the troubles that the grip of the builder inflicts on horticultural societies in and around large towns.

DENDROBIUM DALHOUSIEANUM.—Our illustration, p. 157, exhibits this handsome species in excellent form as grown by Mr. D. G. SKELTON, the gardener at Mount Pleasant, Bishop's Auckland, who kindly furnished a photograph, of which fig. 45 is a reproduction. The species, a native of Borneo, and introduced to Chatsworth in 1837 by Gason, is now pretty well known in this country. It is a noble-looking plant, evergreen, large flowered, and producing its blossoms in the spring from the leafless stems for several years in succession. The stout, terete, sub-fusiform stems grow from 4 to 8 feet in height, and they are prettily marked with crimson. The sepals and petals are of a tawny yellow with a margin of rose colour. The lips is in the front, whitish, and at the base of a pale yellow tint marked on either side with a large purple blotch, the inner edge of which is furnished with a fringe. Plants have been noted with forty-three blossoms on a stem, and a total number of 410 on a single plant.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, March 9, in the Drill Hall, James Street, Westminster, from 1 to 4 P.M. At 3 o'clock a lecture will be delivered by Professor H. M. V. STALLARD, F.R.S., on "Microscopic Gardening."

FIG. 15.—*DENDROBIUM DALHOUSIANUM*. (CULT. 156)

THE ROYAL GARDENERS' ORPHAN FUND.—A meeting of the executive committee was held on Friday, Feb. 26, when W. MARSHALL, Esq., was again elected chairman of the committee. Amongst others the following special receipts were announced. The Chislehurst Gardeners' Mutual Improvement Society's Concert, £23 12s. 6d., a special vote of thanks being accorded; Messrs. BUNYARD & Co., Maidstone, £5 5s.; Mr. O. THOMAS, Frogmore, £2 2s.; Mr. T. WHILLANS, Blenheim, £2; Isle of Wight Horticultural Society, proceeds of lecture by Mr. H. J. JONES, £1 2s.; Miss NOBLE, Henley, £1; Mr. J. KIRLING, proceeds of skating on Knebworth Lake, £1s. 7d., and several smaller sums. The result of the election was announced, whereby thirteen children are placed on the Fund, and the respective guardians appointed. The mothers in each case undertake the duties.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual meeting of this estimable gardening society will take place on Monday, March 8, the chair being taken at 8 P.M., by Mr. A. DEAN.

KEWITES: PRESENT AND PAST.—The annual meeting of the Kew Guild was held in the lecture-room at Kew on the 25th ult., when the popular president of the Guild and curator of the Gardens, Mr. GEO. NICHOLSON, occupied the chair. The report of the committee, though giving rise to considerable discussion, was upon the whole a most satisfactory one, and it was passed by acclamation. The Guild has now a sum of £10 invested, and a balance besides. All the members of the committee were re-elected, and additional ones to represent Kewites abroad and in the Colonies were appointed. Mr. J. AIKMAN retires from the secretaryship, with the thanks of the Guild, and the office will in future be combined with that of the editor of the *Journal*. Two auditors were also appointed. It was suggested by several members that as soon as the committee could see its way to the publication quarterly of a modified edition of the *Journal*, the members of the Guild would be glad to welcome it. If the association continues to give effect to the vitality it possesses, it will undoubtedly be of increasing interest and service to all gardeners who have passed through Kew, and to national horticulture. We desire to urge any past Kewites who have not yet closely identified themselves with the movement, to do so at once. Communications should be addressed to the editor of the *Journal*, Mr. W. WATSON.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, March 8, 1897, when a paper will be read by the Right Hon. HORACE C. PLUNKETT, M.P., on "Agricultural Co-operation;" the chair to be taken at 8 o'clock. The third of four meetings of examinees and students authorised (subject to certain conditions) by the council to be held during the present session, will take place in the first floor room of the temporary premises, Savoy Street, W.C., on Monday, March 15, at 7 P.M., when a paper will be read by Mr. R. R. ST. J. MATTHEWS on the "Housing of the Working Classes." All inquiries with reference to the Junior Meetings should be addressed to Mr. A. NORMAN GARRARD, 8, Frederick's Place, Old Jewry, E.C.

COMING EXHIBITIONS.—Of the horticultural display that will be made in the United Kingdom during the present year, that of the—

SHROPSHIRE HORTICULTURAL SOCIETY, which will take place at Shrewsbury on August 18 and 19, will be one of the most important. The committee has announced its intention to make the exhibition commemorative of the sixtieth year of HER MAJESTY'S reign. In order to make it successful in this respect, the presence and co-operation of the Royal Horticultural Society has been asked, and as most of the readers of this journal are aware, the request has been cordially accepted. The schedule issued by the Shropshire Society is before us, and from this we observe that a sum approaching £900 is offered in cash prizes in the Society's schedules for the year. The list of silver medals, cups, and extra awards is also a very

long one, and includes two specially designed Victorian medals offered by the president of the Society, a Veitch Memorial Medal, the gold medal of the Worshipful Company of Fruiteers, a gold Banksian medal of the Royal Horticultural Society for the exhibit (non-competitive) which best represents the progress of horticulture during the last sixty years. Some of the principal classes that are likely to create features at the Show are the following:—A group of miscellaneous plants upon a space of 450 square feet, the 1st prize for which is £35, and the others proportionately large. Then we notice the 2nd class for a group of ornamental foliage plants, Palms, Ferns, &c., to be arranged upon a space of 250 square feet. The 1st prize for this is £25. Artistic arrangement in the above classes will be chief point in the competition. The liberal prize of £25 is offered for the best collection of twenty stove and greenhouse plants, and for lesser collections of similar plants the prizes are as tempting. As an encouragement to the exhibition of new plants, the Society offers a Gold Medal for the most meritorious flowering or foliage plant not in commerce before January 1, 1897. Turning to the cut-flower department, the most important class in this section is that for a display of floral arrangements, for which three prizes amounting to £37 are offered. Most of the flowers in season will be exhibited in special classes.

The *Decorative Dessert Table* will undoubtedly create much interest among fruit growers (and fruit eaters). For the particulars of this competition the reader must turn to the schedule, but we may add that the 1st prize for this valuable feature of the fruit classes will consist of a Veitch Memorial Medal and £5, presented by the Veitch Memorial Trustees, and 12 guineas given by the Society.

The *Victorian Fruit Class* should be of even greater interest. It calls for 60 dishes of fruit, tastefully exhibited with cut flowers, &c. The winner of the 1st prize will obtain the Gold Medal of the Fruiteers' Company and £30. We must omit to mention other classes in this schedule, including the vegetables. Enough has been said to show that the Shropshire Horticultural Society is flourishing and enterprising.

WOLVERHAMPTON FLORAL FETE.—Encouraged by the success that has hitherto attended the horticultural exhibition that now takes place annually in the West Park, Wolverhampton, the committee has again issued a catalogue of classes that indicates continued and increased vitality. The next exhibition will be held on July 13, 14, and 15, and we notice that seven of the classes are described as international ones. Among these are classes for sixteen stove and greenhouse plants, for a group of plants arranged for effect upon a space of 450 feet, for eight exotic Orchids, and others for Palms, fine foliage plants, and Ferns. In the two first classes the prizes amount to £55. There are a number of Rose classes, including one for seventy-two distinct varieties. As usual, there are numerous classes arranged for cut blooms of different species, this being a section that usually is a marked feature of the Wolverhampton exhibitions. Fruit and vegetables are fairly well represented, especially remembering the date at which the show is held. Some of the classes in all sections are reserved to gentlemen's gardeners, others to amateurs, and there are considerable inducements held out to cottager exhibitors. Altogether there are 111 classes, and a good display may be looked for.

COUNTY BOROUGH OF HANLEY HORTICULTURAL FETE.—It has been determined to obtain in Hanley what has already been inaugurated in other populous districts, viz., a Horticultural Fete. Of what is known as the Staffordshire Potteries, the county borough of Hanley occupies a central position, and is, therefore, in the midst of a very large populace. The schedule that has just been issued by the committee is a bold one, and if other established societies are not sufficient for the horticultural exhibitors' time and resources, the Hanley exhibition, to be held on July 7 and 8, will be a success. The schedule embraces five divisions, including open classes, gentlemen's gardeners',

or amateurs' classes, local class sets, cottagers' classes and one for the best kept greenhouse in the county borough of Hanley. The cottagers' section is very limited, and in proportion to the open classes, we think they should have been trebled at least. It is amongst such cultivators that the greatest opportunity exists for a society like this to do good. In all there are seventy-nine classes, and the prizes offered are equal in some instances to those offered by societies that have existed for years and are widely known. Many of the classes are interesting ones: an instance may be given of that for a group of Orchids in bloom arranged for effect, with the optional use of Ferns, upon a space not exceeding 100 square feet.

BARON SCHROEDER'S ORCHIDS.—We are informed that the QUEEN, the EMPRESS FREDERICK, and the PRINCESS BEATRICE, visited Baron and Baroness SCHROEDER at Egham on March 2, and were highly delighted with the Orchids shown them by the Baron and his gardener.

DISASTROUS GALE IN WEST OF ENGLAND.—On Wednesday morning last (writes Mr. A. Hope), between 7 and 8 o'clock, a fierce gale of wind blew across the county of Devon for about an hour, uprooting trees, tearing off roofs of houses, and stripping gardens in all directions. The damage to timber around Exeter is very considerable. Powderham Park, Nutwell Court, and other well-known seats have suffered much damage, many fine trees having fallen. The old nurseries of LUCOMBE, PISCE & Co., now the Exeter Nurseries (Messrs. SOLATER BROTHERS), have suffered to the extent of over a thousand pounds, the large Camellia-house being completely wrecked, with other houses near it. On the Streatham Hall property over sixty fine trees have succumbed, and in Northernhay and the other pleasure grounds of Exeter, Elms of 100 and 200 years old have been uprooted in large numbers. Messrs. VERRILL have suffered also, but not to any great extent, although so fierce was the gale that frame-lights were in some instances carried many yards from their places, and, of course, smashed to pieces.

MARRIAGE OF MR. GEO. MONRO, JUN.—On Tuesday, the 2nd inst., Mr. GEO. MONRO, the second son of Mr. GEO. MONRO, of Covent Garden, was married to HELENA, daughter of EDWARD OLIVER, Esq., of Haverstock Hill. The ceremony took place at the Haverstock Congregational Church, where, it may be stated, Mr. E. G. MONRO, the eldest son, was married a month ago to a daughter of T. GURNEY RANDALL, Esq., England Lane, N.W. As on the former occasion, the chapel was crowded with invited guests and others, and was profusely decorated with flowers. A similar reception was again held at the Vestry Hall, Hampstead. The happy couple afterwards left for St. Leonards-on-Sea, and many of the guests proceeded to view the handsome presents that were on view at 96, Haverstock Hill, the residence of the parents of the bridegroom. In celebration of the double event, Mr. MONRO'S employes of all grades were invited to dinner at Simpson's, Strand, on Saturday, the 27th ult., when there were about sixty persons present.

"ARBOR DAY" AT EYNSFORD, KENT.—In the quiet little village of Eynsford, in Kent, there took place on Saturday, the 27th ult., the first celebration of an "Arbor-day." The inauguration of similar institutions in all parts of the country is a step which Mr. RUDOLPH COOKE, M.P. for Hereford, has recommended as a means to excite the interest of country people in the question of cider manufacture, and to induce them to plant vintage trees of the best kinds of Apples for this purpose. Though our American cousins may be excused for vieing with humour the commencement of "Arbor-day" celebrations in a country so populated as our own little island, if it proves helpful in drawing attention to the necessity of replanting most of our old orchards, and giving increased attention thereto, it will justify its existence. The cider industry is deserving of encouragement from horticulturists and all who desire to see our available land made more valuable for cultivation. The first "Arbor-day" passed off successfully, and this was

due in a large measure to Mr. TILL, of Eynsford, who was the chief promoter. At a meeting held under the presidency of Sir GEO. BIRDWOOD, K.C.I.E. &c., a resolution was passed urging the Government to appoint a commission to enquire into the condition of English orchards.

—A DIRECTORY OF TITLED PERSONS FOR THE YEAR 1897.—This little volume is intended as a supplement to *Hiltner's Almanack*. It contains a history of the monarchy and of the peerage, with full details of the Royal family, and with an account of the Queen's coronation—sixty years ago. Then follows in one continuous alphabetical sequence a list of peers, baronets, knights, privy councillors, dowagers, bishops, and of everyone with a recognised title. A great amount of labour and care has obviously been expended on this volume, which, from the facility of reference which it offers, and its completeness, will be most useful.

FRUIT-CANNER.—According to the *English Mechanic* of February 19, 1897, a patent has been granted in the United States to A. C. McCUTCHEON, of Sparta, Mich., for an improvement in canning fruit. Instead of cooking the fruit before canning, the fruit is first put in the cans, and the latter are placed in a specially-designed steamer, whereby the fruit may be cooked by steam, retaining more perfectly its full flavour and colour. The body of the steamer is placed in a boiler-pan adapted to be set on a stove, and a short distance above the water is a perforated diaphragm on which cans may be set, there being another perforated diaphragm a short distance higher up within the casing, on which cans may be set, and to which steam is supplied by a central pipe and branch pipes, maintaining an equal heat in the upper and lower sections.

WILD BIRD PROTECTION AND NESTING BOXES.—Mr. J. R. B. MASEFIELD is about to publish a work on this subject. The object of this book is to furnish reliable particulars of the ancient and modern laws relating to wild bird protection, including orders obtained by county councils for the local protection of wild birds and their eggs, and to give full particulars and illustrations of artificial bird nesting boxes, ledges, and holes, with instructions how to make and affix them, also figures of various designs of nesting boxes recommended by the Rev. JULLIAN TUCK, the author, and others. The book is fully illustrated by nine full-page colotype plates taken from photographs of nesting boxes, &c., *in situ*, which have been actually used by wild birds. The publishers are TAYLOR BROS., Leeds.

TRURO DAFFODIL AND SPRING FLOWER SHOW.—We learn that owing to the unusual forwardness of Daffodils and other spring flowers this season, the committee of the above have decided to alter the date of the show to March 16 and 17. Notice of entries should be sent not later than Tuesday, the 9th inst., to the Secretary, Tregys, Perannell, Cornwall, who will supply entry forms on application.

MR. WILLIAM MILNE.—The death of this gardener, in his forty-third year, is announced. After some years of service at Levens Hall, Trencham, and previously at Wimbleton House, he succeeded in softening of the brain and concurrent blindness. He was elected to participate in the benefits of the Gardeners' Royal Benevolent Fund at the last election only. He leaves a widow and four children. Pitiable cases like these emphasise the necessity for our gardening charities, and render imperative the duty of supporting them.

BOTANICAL MAGAZINE.—The March number is particularly interesting. The plants figured are:—*Hibiscus chinensis var. multipectus*, the *W. multipectus* of Van Houtte's *Plante des Serres*. It resembles chinensis, but it has smaller leaves with a larger number of leaflets, and much longer racemes, and more numerous but smaller flowers. L. 7522; Kew. *Holboellia orthoceras*.—A South African terrestrial Orchid, with radical, sessile ovate tessellate leaves, and erect scape, bearing at the top racemes of white flowers somewhat spirally arranged, as in *Spiranthes*.

The lip is broad, projecting, rather deeply lobed, ending at the base in a long spur, t. 7523; Kew.

Grevillea Hilliana.—An east Australian Proteal with pinnatifid, broadly-lobed leaves, silky on the under surface. The greenish flowers are densely compacted in shortly-stalked, axillary spikes, 5 to 6 inches in length. La Motzola, Comm. F. Hanbury; t. 7524.

Deudorhinum sarawacense.—A Burmese species, with slender stems, ovate leaves, and small white, flattish flowers nearly an inch in diameter. The three-lobed lip scarcely exceeds the segments, the two side lobes are small, erect, yellow with red stripes, the anterior lobe ovate, acute, yellow at the base, t. 7525; Kew.

Didymocarpus malayana.—Hook. f. in *Gardeners' Chronicle*, 1896, ii., 123, f. 21.

CHIONOSCILLA ALLENI.—This hybrid between *Chionodoxa sardensis* and *Scilla bifolia*, is in fine flower at Kew. The plant came in some bulbs from Mr. WHITTALL of Smyrna, and has also been raised artificially.

GERMINATION.—It is currently reported in the text books that the radicle escapes through the micropyle of the seed by virtue of the pressure which it exerts during its growth, and which enables it to force its way through the tissues. The real force seems rather to be a ferment[which is formed in the radicle, and which erodes and dissolves the tissues, and thus enables the radicle to escape.

PUBLICATIONS RECEIVED.—*Ueber den Gartenbau in Russland*, Von Dr. UDO DAMMER. Jahrgang, 1897 (Buxenstein, Friedrichstrasse, 210, Berlin).—*Liste des Confirés cultives dans le Parc de la Pierrine, à Chambéry*. Souvenir de la Visite de la Société Suisse des Forestiers, August 10, 1896. Extrait de l'Herbes Boissierianus (Lausanne, Imprimerie Georges BRIDEL & Cie).—*Les Fruits et les Légumes aux Halles Centrales de Paris pendant l'année 1895*. Par MM. D. BOIS and G. GIBALT. Reprinted from the *Journal of the Société Nationale d'Horticulture de France*.—*Transactions of the Scottish Horticultural Association*, Constitution and Bye-laws, Syllabus for Session 1897, and Twentieth Annual Report. We are pleased to learn that the past year was a satisfactory one, and that the prospects of the Association for the future seem propitious (Edinburgh: SANSON & Co., Easter Road).—*Fifth Annual Report of the Women's Branch of the Horticultural College, Swanley, Kent*. This association seems to be still flourishing and extending, the report for the past year being in every way favourable.—*The Fruit-growers' (Illustrated) Year-Book*. A useful sheltering handbook, addressed to all growing fruit, whether for private consumption or for market. It is edited under the direction of the Earl of WINCHILSEA, and the (London) Office is 30, Fleet Street, E.C.—*The Fruit-growers' Catalogue and Market-seeders' Guide*. This serviceable directory is edited by SAMSON MORGAN, author of many agricultural and gardening books. It is especially intended for "market seeders, shippers, growers, brokers, retail traders, and salesmen," whose interests are herein specially considered (Horticultural and Agricultural Bureau of Information, Adelaide Street, Charing Cross).—*Transactions of the Royal Scottish Agricultural Society*, vol. xv., part i. (DOUGLAS & FOLIES, Castle Street, Edinburgh). It is satisfactory to note how flourishing this society continues to be.

—*Studies on American Grasses* (U.S. Department of Agriculture, Division of Agrostology: Washington). This bulletin (issued February 6) includes papers on the Genus *Xiphiopsis*, by F. LAMSON-SCHREINER; List of Grasses collected by Dr. E. PALMER near Acapulco, Mexico, by the same contributor; Mexican Grasses collected by E. W. NELSON, by F. LAMSON-SCHREINER and JARED G. SMITH; American Panicums in the Herbaria at Berlin, by THUR. HOLM; Native and Introduced Species of Hordeum and Agropyron, by F. L. SCHREINER and J. G. SMITH.—*Bulletin of Miscellaneous Information from the Royal Botanic Gardens, Trinidad*. Part i., vol. iii., for January. The contents include papers on *Petrea* (species), the Cocorite Palm, *Pithecolobium Saman*, &c. There is also a note relating to

the decreasing rainfall of Trinidad, which is attributed to the disappearance of the forests. It is at least advisable that this drought be carefully noticed and chronicled, as it may be due to causes which, if taken in time, may be coped with before serious damage is effected.—*Proceedings and Journal of the Agricultural and Horticultural Society of India*. Vol. x., for October-December, 1896 (Calcutta, Metcalf Hall). A satisfactory report of a veteran society still doing good and appreciated work.—*Agricultural Journal of the Cape of Good Hope* (Published by the Department of Agriculture). The fortnightly issue of this publication, dated January 14, contains reports of crops in various districts, and prospects for the future harvests. Stock-farming is included among the subjects treated of. *Erythra*, edited by WILLIS LINN JEPSON (published in Berkeley, California, in London, and in Germany). The issue for January contains Notes on *Puccinellium erosum*, by the Editor; Notes on the Pollination of Californian Mountain Flowers, by A. J. MERRITT; New West American Fungi, by J. L. ELLIS, and E. M. EVERHART; Botanical Explorations in California in 1896, &c.—*Report of the Botanist L. R. Jones*, of the Vermont Experiment Station. Reprinted from the Ninth Annual Report.—*Royal Botanic Gardens, Glasnevin, Dublin*. List of seeds for exchange during 1897. A long catalogue including some desirable species.—*Favourite Flowers of Garden and Greenhouse*. By EDWARD STEV, Nos. 26 to 28 of vol. iii. have now been issued, and, like former numbers, are sure to be appreciated by those who like descriptive and cultural notes and attractive coloured plates. (FREDERICK WARNE & Co., Bedford Street, Strand).—*Familiar Wild Flowers*. By F. E. HULME (CASSELL & Co., London, Paris and Melbourne). The First Part of a new edition of this popular work has now appeared. The whole issue will consist of twenty-one parts, price 1s. each.—*Dictionnaire Pratique d'Horticulture et de Jardinage*. The 58th Livraison of this work is continued as far as *Rhipsalis*, half of which genus is therein treated of.

ORCHID NOTES AND GLEANINGS.

CATTLEYA PERCIVALIANA.

DESPITE the fact that on its first introduction some of the best specimens realised over £100 each, *Cattleya Percivaliana* has never been a favourite Orchid; and yet the flower of a good variety is very handsome. An inflorescence of the best form is sent by W. H. Lumsden, Esq., Balmaloe, Aberdeen (gr. Mr. G. Roberts). The flowers are as large as those of an ordinary *C. labata*, the broad sepals and petals of a bright purplish-rose tint; the finely-expanded and crimped lip of a dark reddish-orange at base and centre, the front lobe being of a rich velvety crimson-purple. Few Orchids have displayed such rich colouring or such neatly-formed flowers.

ONTOGONUM CRISPUM.

As a rule, the commodity of high prices pertains to the spotted forms of *O. crispum*, rather than to the fine white varieties; but whenever a really fine example of the latter appears, it commands quite as much admiration as the blotched kinds, and a proportionately good price when sold. One of the best, if not the best, forms of white *O. crispum* which has yet appeared, was put up at auction by Messrs. Protheroe & Morris at their rooms, 67 and 68, Cheapside, on February 26, when, after a spirited competition, it was purchased by H. T. Pitt, Esq., Rosslyn, Stamford Hill, for 31 guineas. The plant bore a noble inflorescence, the flowers resembling of the *O. c. Duchess*, which caused a great sensation some years ago; but those of Mr. Pitt's plant are much larger, the substance is firmer, and the flower better in every respect. X

LYCASTE SKINNERI VAR. TOM LOFFHOUSE.

Among the many varieties of *Lycaste Skinneri* which date from the days of G. Ur Skinner, who used to grow them in one of his rooms at home, there

have been very few of first rate excellence. Personally, I have never seen one to equal the highly-flamed and beautiful one named Dawson, first flowered in the Meadlowbank collection quite thirty-five years ago. Unfortunately, it is not in existence now; one of the more prominent of existing forms is Imperator, similar to which in character is the variety recently in flower at A. Warburton's, Esq., Vine House, Haslingden, Lancashire (gr., Mr. Tom Lofthouse). This variety has fine, broad, oblong-ovate sepals of a bluish ground, with broad, straight, pink lines about equidistant over their surface. The petals are highly flamed and of good substance, nestling close over the column and half enveloping the lip. The lip is all but pure in colour—far more so than in Imperator. Mr. Warburton's Lycastes are all well grown in an intermediate temperature, these plant having a dozen of strong, roundly-ovate pseudo-bulbs with strong leaves. J. A.

GROUP OF PLANTS IN FLOWER OF DENDROBIUM WARDIANUM.

In Mr. Warburton's Lodia and Cattleya-house, which is a comparatively lofty hip-span, is a splendid set of *Dendrobium Wardianum*, excellently cultivated, and yielding at the time of my visit, 2000 expanded flowers. One plant alone had about 120 flowers. These are suspended above the Lodias. There are no plants exactly alike. One of the most striking ones was of normal form, but had a yellowish-green shade, particularly about the lip, which with the bright crimson eyes contrasted so well. Mr. Lofthouse waters very sparingly even in the growing season, and he has not subjected any plants to the temperature of a cool-house. The result shows that those who starve their plants to get them to set buds or to arrest second growth are in the wrong, and the sooner they follow the practice adopted at Vine House, Haslingden, the better for themselves. J. A.

DENDROBIUM DENSIFLORUM.

A very fine example of this species is now in bloom in the collection of Orchids at Greenlands, Henley-on-Thames. It is a finely-branched example, carrying twenty three spikes, large, full, and very showy. R. D.

MUSTARD FOR WIREWORM.

WHETHER a farmer or a horticulturist he may consider himself a happy man who has not suffered more or less from the ravages of the wireworm. As the latter, I have been fortunate in meeting with a remedy which I believe would also be of great benefit to the farmer. I have something over an acre of garden, mostly new soil. It is no wonder therefore, if my crops have been more than decimated by wireworm.

When sowing some Peas last summer I remembered a remedy which I had used some half century ago in the case of grain crops. It was then the custom to sow Mustard seed, and plough it in previous to Wheat.

I applied therefore to the housewife, and from a tin of Coleman's mustard powder, I scattered some over the Peas in the trench for a couple of yards before they were covered up, the result was a very fine crop in this portion, the Peas coming up thickly, and with that dark bluish-leaf which betokened the rich growth that was to follow.

Last summer I also applied this dressing to other crops, especially Onions and Carrots, with marked success. I much appreciate the latter when very young, as does also the wireworm. I usually have five or six sowings to furnish me with tender half-inch roots in due succession, and when I had a difficulty in procuring anything like an even crop, have by a moderate use of my powder no difficulty in securing faultless rows of this delicious vegetable, the roots neatly touching each other.

So also with Beans of various description. In previous years, when tired of waiting for their appearance above ground, I had examined the growth and found the seed burrowed through and through by the wireworms. I now obtain splendid crops without intermission. On one occasion, when raking

over the ground previous to sowing a crop of Sutton's early Marrowfat and Sharpe's Queen, I found so many wireworms that I put a hundred into a cup and dusted freely some mustard-powder over them. In ten minutes they were all dead, pale and motionless. The gardener, who, like most of his class, was a stubborn unbeliever in new remedies, then sowed the two rows, and I dusted half of each row with my powder. He covered in the Peas, and in a few minutes he came after me. "I believe, Sir, there is something in your powder, for the wireworms seen coming up out of the ground." The result was a remarkably fine crop of these Peas. From the first day they appeared above the ground the contrast to the undressed portion of the rows was undeniable. I am this spring dressing every crop in the same way, including early Potatos.

To my flower garden I have hitherto lost 80 per cent. of my bulbs, Carnations, &c., *Glaadioli* shoots have in most cases had their shoots pierced through by wireworms. Iris roots also I have found with the inside completely eaten away and the skins alone left, looking with their rootlets like an empty glove. I am now trying the effect of mustard in such cases, and I hope that some of your readers will make experiments in this direction also. A very small quantity of mustard is sufficient, more is dangerous. It must not be supposed that I continue to use "Coleman's pure mustard," as at first, now I apply for the coarser description—siftings—called "mustard-dross." It is remarkable that this commodity after being pressed for the extraction of oil is exported to Holland, &c., for dressing land infested with wireworm. It is possible that my adoption of it is not so unique in this country as I suppose. A small (half-gallon) wicker basket I find the most convenient for dusting the dry mustard-dross with. I may add that it is probable the unexpressed oil in the dross acts as a manure in stimulating the growth of crops, as I have above stated. But I will repeat, the dross must be used carefully—a very little seems to sicken the wireworm—just sufficient dusting to produce a little greyness of colour; dropping it in patches enough to cover the soil seems fatal to everything beneath it, vegetable or animal. When deposited thus thickly, the mustard-dross becomes a grey mould and loses its power. I overdid Iris roots, the powder turned mouldy, and seemed to have lost its virtue, for I found six vigorous wireworms at one root unaffected by the grey mould close to them. Worms succumb to a slight application, but it secures caution that the dry and scaly wireworm should not be withstood the touch of this dry powder, which seems to pierce the joints of its armour. J. P. [The use of mustard in treating land infested by wireworm is advocated by Miss Ormerod in her *Manual of Injurious Insects*. Ed.]

SWEET PEAS.

THE increased popularity of this beautiful annual, which has been so greatly improved during the last decade, has caused me to endeavour to trace its early days, with the actual date of its introduction into this country. It seems that the original variety, with dark purple standards and dull blue keel and wings, first came to us from the Island of Sicily, in the year 1699. Dr. Petiver mentions the fact in a paper he communicated in 1713, to the Royal Society, and which will be found in the *Philosophical Transactions* (see vol. xxviii., p. 210). It seems that the seed was sent to Dr. Uvedale, who was an enthusiast in plants, and had a curious collection of exotics in his garden at Enfield. It was here that the original plants flowered, and they were visited by many experts, including Dr. Plukenet, author of one of the *Herbals* of the day.

Another variety called Painted Lady, with white wings and keel, and a flesh-coloured standard, appears to have been evolved from this original form. Yet some writers of a later date tell us that this latter species came from Ceylon. I can find no reference in any of the books available and published during the next few years, to the Sweet Pea, outside the later editions of Miller, who does not, however, write

anything that is fresh; and the first mention I have been able to trace in a seedsman's list is in that issued by John Mason, who traded at the Orange Tree, 158, Fleet Street, London. His Catalogue, issued in 1800, is a solid little book of 111 pages, and in it he offers black, purple, scarlet, white and painted ladies, new and old. He calls them early annuals, to be sown in open borders from March to May. In 1837 I notice Mr. Carter offers a similar list, with a striped form added; whilst in 1850 he includes "new large-flowered." To 1860 he gives nine varieties and a yellow-flowered one, and also blue-edged, to which the Royal Horticultural Society gave a First-class Certificate many years later. On August 22, 1883, this novelty was first named Blue Hybrid, and it was understood to have been a true hybrid between the annual white Sweet Pea and the perennial Lord Anson's Blue, now almost lost to cultivation. It was the outcome of a series of experiments made with the object of raising a real blue-flowered variety by Col. Trevor Clarke of Daventry. On July 11, 1865, Mr. Stephen Brown of Sudbury gained a similar honour for Scarlet Invincible. From about 1882 to the present time, according to the records of the Royal Horticultural Society, Mr. Eckford has held the field, and he deserves the greatest credit for the high state of perfection to which he has brought this charming species. *Seedsman*.

A GROUP OF LILIUM CANDIDUM.

THE common white Lily, the painter's Lily, is well shown in fig. 46, taken from a photograph kindly sent by Mr. Jeffery, Moor Court Gardens, Chislehurst. The accompanying note tells us that last year the bulbs flowered remarkably well in the hot sandy soil of the garden. He had not always been so fortunate, however, in obtaining fine results. When the bulbs were first obtained in the autumn they were planted in ordinary garden-mould, in clumps, dotted about in different parts, and the following year they flowered well. The next year they appeared to be gradually dwindling away, very few perfect flowers being produced; and in August the bulbs were taken up, and an examination showed that there were hundreds of small white mites harbouring between the scales of the bulbs. The bulbs were washed in warm water in which a small quantity of petroleum was incorporated, in the hope of killing the mites, and immediately planted into light, rich soil, in which the bulbs have flourished ever since. This species deserves a little more attention from gardeners than, as a rule, it obtains, and means should be taken to clear the stems and blooms of aphides, which are apt to be troublesome.

BELGIUM.

HORTICULTURAL EXHIBITION AT TERVUREN.

THE programme for flower, vegetable, and fruit shows to be held this year at Tervuren, on the occasion of the Brussels Universal Exhibition, is just published. The horticultural shows will be on the following dates:—Inaugural exhibition, May 9 to 12; Cat Roses, June 12 to 14; general exhibition, July 21 to 25; Chrysanthemum show, November 6 to 8. Exhibitions of vegetables will be held on May 15 to 17, June 11 to 13, August 2 to 4; September 25 to 28. Fruit shows on the same days, but not in August.

The prizes will consist of diplomas of honour, and of Gold, Silver, and Silver-gilt medals. At the inaugural and general shows, medals are offered for the most tasteful groups arranged by the exhibitors, and a contest of choice and rare plants.

NOTES FROM BRYANSTON, BLANDFORD.

BRYANSTON, the fine estate of Lord Portman, is charmingly situated near to the picturesque town of Blandford. The visitor enters the grounds from the town by a gateway of noble proportions, flanked by

quaint lodges, whence runs a road in admirable keeping, and adorned on either hand with a variety of tree and shrub, and of the latter some gigantic *Buxus* form a striking feature. The mansion is a modern building standing on an extensive lawn skirted on one side by a wood. The river Stour bisects the lawn; and from this part of the garden good views of Blandford town, the Dorsetshire hills, and distant and adjacent woods are obtained, the whole forming a very pleasing prospect. Bryanston is a well kept-up domain, and both gardening and farming are carried on in accordance with modern ideas; but it is of the gardens that I chiefly wish to speak.

These are under the charge of Mr. Arthur Allsop, an excellent gardener, who appears to be fully equal to the great demands made upon his abilities. There are very large quantities of cut-flowers required, and especially in the winter and spring, and Lily of the Valley, Hyacinths, Tulips, Narcissus, *Staphylea colchica*, Lilac, *Azalea mollis*, and *A. indica*, are forced in

Violets are made a special feature, and never in all my travels have I witnessed such an abundance of fine flowers. *Marie Louise* is the favourite variety, and some 2000 plants of it are grown in cold frames. Several of the flowers that I measured were larger than a florin, and there seemed to be as many flowers almost as leaves on the plants. Mr. Allsop has evidently hit upon the right kind of treatment for the Violet in winter; and perhaps this note, when he reads it, will induce him to describe his methods. Judging from photographs which I saw of such summer flowering subjects as *Gloxinas* and *Streptocarpus*, these plants must be grown in grand style. Numerous foliage plants for use in indoor decorations, for which there is a fairly constant and large demand, occupy several of the glass-houses. The vineries and peacheries already started had a thrifty look, and will be worth seeing at a later date. The fruit and kitchen-gardens are laid out on a very extensive scale, and are very productive, as they needs must be, to supply the needs of so large an establishment. The pleasure-

It is to be feared that the majority of the Council regard the papers as bores, and show their appreciation of them by their absence. *A. Fellow.*

HYBRID PRIMULAS.—Reading the remarks of "J. H. W." with respect to his efforts to intercross *P. obconica* and *P. Sieboldi*, which like to so many other efforts at intercrossing seem to have been a failure, I am tempted to ask whether there is on record any well-authenticated case of the successful intercrossing of two absolutely distinct *Primula* species. In years past I have had many trials in that direction, but never with success. I rather think that indefatigable and able hybridist, the nurseryman to Messrs. Sutton & Sons (Mr. James Martin) could tell a long story with respect to efforts he has made from time to time with diverse species. It is generally understood that we owe the florists' *Auricula* to the intercrossing of *P. auriculata* with *P. viscosa*; but even if it be so, these are such allied forms that they can hardly be classed as distinct species. The subject is of exceeding interest, and one very reasonable too, just now, when *Primulaceae* are just about to bloom. *A. D.*

FIG. 16.—A GROUP OF LILIU CANDIUM, GROWN IN THE GARDEN OF A. S. BOLTON, ESQ., MOOR COURT, HEADLE. (SEE P. 160.)

great batches to meet the demand. One of the things very largely grown is *Freesia refracta alba*, of which 4000 potsful are annually got ready. The *Cyclamen* is cultivated with equal success, and at the present time about 300 plants are in profuse flower, the varieties *Butterfly* and *Vulcan*, many of them with fifty to sixty flowers, being very conspicuous objects. Tree Carnations, Border Carnations, and *C. Souvenir de la Malmaison* in variety are capitally cultivated. About 200 fine plants of the almost indispensable Carnation, *Miss Jolliffe*, are at the present date in fine bloom. Border Carnations are grown to the number of 2000, and the collection includes many of the finest varieties. Of Carnation *Souvenir de la Malmaison* about 100 healthy plants will form a display of themselves for some time to come. Many plants of the rising favourite *Marguerite* Carnation are grown in 5 inch pots, which have afforded a rare harvest of bloom, and are still affording some flowers. This is a very valuable type of Carnation to grow for cut flowers; moreover, its cultivation presents no difficulties.

grounds and flower-gardens cover many acres, still they are being enlarged and improved. *Alfred Outson, F.R.H.S.*

HOME CORRESPONDENCE.

LECTURES AT THE DRILL HALL.—I read Dr. Carville's complaint concerning the reading second-hand of the papers or lectures sent to the Council of the Royal Horticultural Society for the Tuesday meetings there. Now, in connection with ordinary gardeners' associations, of which there are so many doing excellent social and educational work in the Kingdom, it is the rule to pay readers of papers any out-of-pocket travelling expenses they may incur; thus, they rarely have second hand papers. Why cannot a Society, such as is the Royal Horticultural Society, so long as it invites papers of this nature, offer to repay the readers such expenses as they may incur in coming to London for the purpose? Of course, discussion in the absence of the writer of the paper is absurd. It is of not the least use to object to any statements made in the paper when the writer is not there to defend them.

A GERMINATING APPARATUS.—The costly and elaborate arrangement illustrated on p. 143 of your last issue, is totally unnecessary even for the most exact work. The most practical and useful form, which I myself used for many years, was constructed as follows:—The bottom of the apparatus consisted of a flat copper box about 1 inch deep containing water; the contents of one 3 feet long by 16 inches wide are about 2 gallons. To the sides of this box are soldered the copper-frames carrying the glass sides, these being fixed, the top glasses only being removable. For a germinator of this size for ordinary seeds not requiring very high temperatures, say under 70° Fahr., it is sufficient to place under the tank an ordinary No. 000 Bray's lighting burner at a distance sufficient to prevent the possibility of the flame touching the copper. A gas consumption of 1 cubic foot per hour will maintain a rise of about 35° Fahr. in the tank over the normal temperature of the room, and owing to the very slow changes caused by the bulk of water, manometers and pressure-governors are quite unnecessary. In an ordinary living room a gas consumption of 3 cubic foot per hour will maintain an average 75° F. bottom-heat, and 1 cubic foot will maintain over 90° F., a temper-

nature at which most, if not all, seeds of tropical plants germinate rapidly. In the apparatus referred to the pots are covered with glass plates, to guard against falling spores; but under any circumstances, the products of combustion do not affect the most delicate plants in the case. No doubt, some small part of the products will get in the case from the top; but even if the quantity that gets in the result would be the same, as the moisture condensing on the glass would at once take up any sulphur compounds present. In such a case as this I have grown for years in succession Orchids and delicate filmy Ferns, the room in which the case stood being lighted by gas every evening, without any special ventilation. *Thomas Fletcher, Gt. Parkhill, Cheshire.*

THE BAY LAUREL (LAURUS NOBILIS).—I send you a specimen showing how fruitful the Sweet Bays are here this past season. We have a fair crop of fruit in average years, but I have never seen the berries so plentiful as they are at present. Some of our bushes look very ornamental indeed with their black glossy berries. *D. C. Powerscourt.*

SEEDING CYCLAMENS.—The culture of Cyclamens from seed can be made very profitable, but it needs great care throughout, and it is especially important that seed should be obtained from plants bearing superior flowers. The best time to select flowers is about the middle of February, and more than nine should not be selected from one plant. They must be gently brushed with a fine camel-hair brush two or three times when the sun is bright, taking care not to bruise the pistil. As soon as the seed-pods are formed, a slight top-dressing of Clay's or Thompson's plant manure may be given. About the beginning of June, the seed will be almost developed, and the plants should be kept rather dry at the root. It is a mistake to throw the corn away when the seed has been gathered, for a Cyclamen if properly treated will thrive for six years at least. When the seed has been taken, and exposed to the sun for about three weeks, and watered weekly. The dry leaves should then be cut off close to the bulb with a pair of scissors, care being taken not to tear the bulbs. Afterwards put them in cold frames and slightly shade, watering them about three times a week with fresh cow manure-liquid. After the bulbs have shown signs of new growth, they should be taken out and potted rather firmly in a compost of three parts good fibrous loam, one part of leaf-mould, and a small quantity of silver-sand. Give them a temperature of 60°, and a little air when the sun warms until they have made a fair amount of growth, when they should be exactly the same treatment as is required by seedling plants. It is a great advantage to exhibitors that flowers from old bulbs come much better and clearer than from seedlings, and generally most of the flowers come at one time. *Charles White, Stercing.*

CYPRIPEDIUM INSIGNE SANDERÆ.—Kindly allow me a few closing observations in reference to Mr. Hardy's supposed plant of this Cypripedium. I may say that it was not by any means a secret at the Manchester Show of November, 1895, that the plant exhibited was the one he bought at the Pickering Lodge sale. Allow me again to call attention to the *Gardeners' Chronicle* of February 6, wherein he says that he never showed his C. Sandere. After noting this, please turn to p. 145 of your last issue, and behold his statement, viz., that the plant exhibited at the show referred to, was not only Sandere, but that it came "straight" from Baron Schroder. Here enough for any honest gardener, and I must leave them for the puzzle expert to solve. I still maintain that the variety shown by him is inferior, and not the original C. Sandere. I quite admit that dividing a plant may cripple the full development of its flowers for a time, but it will never alter their leading features to an extent beyond recognition. *N. S.*

VARIATION AND ENVIRONMENT.—Mr. Drury, in *Gardeners' Chronicle* of February 27, p. 133, calls attention to a very important fact, and one often stated to show that varieties may arise among other plants of the same kind without any apparent "changed conditions of life." Of course Darwin demands that they should so appear as a rule, otherwise there would be no struggle for life, and no scope for natural selection. But both Darwin and Dr. Wallace think that "the country must be undergoing some change" which would induce variations to arise. Mr. Drury shows, what is well known, that varieties do occasionally arise among the parent type, especially

if it be a very plastic one, as in the case of Ferns; but the degree of frequency of such isolated appearances is very small, taken as a whole, i.e., when contrasted with the normal variations in plants distinctly induced by some marked change of environment; and his words really express accurately all that can be guessed as the cause of sporting in Nature.—"It may even be in some subtle local modification of the parental Fern, which consequently produced the modified spore." Precisely so; but then this implies some, however minute, cause presumably to be traced to a new element in the environment, and this is all that is maintained. Usually a plant migrates into a new habitat (by dispersal of its seeds, &c.), and then varies; but if anything happen to it without migration, then, it may vary while still residing among its kind and kin. Mr. Drury asks for "a more extended study of plants in a wild state," but twenty-five years of study of wild plants, with their methods of evolution always kept steadily in view, has convinced me that all the various types of plants, as represented by their vegetative forms, have arisen solely by adaptation to their environment, as I have shown in my last book, *The Origin of Plant Structures*. This conclusion is based on an overwhelming mass of evidence. It is, moreover, thoroughly corroborated by horticulture, as is so well shown by Mr. Bailey. Hence, when a strange form suddenly appears, where we may not be able to see any difference in the environment, the conclusion is inevitable that some "subtle local" influence is at work which has affected that one plant and no other about it. That such is the right conclusion is strengthened by cultivation, for here different forms arise, and sporting is far more frequent than in the wild state. Hence the coincidences between "sporting" and "artificial soils" of gardeners force the same conclusion, that there is, directly or indirectly, a distinct cause and effect—"some subtle modification" of form arising in consequence. *George Henslow.*

GARDENERS' RELIEF SOCIETIES.—I may read with pleasure the remarks made at different times by writers in these pages, in regard to the necessity of upholding the law societies which afford relief to gardeners when past work, and of assisting in the support of gardeners' orphans. I should also much like to see discussed the pros. and cons. of a scheme for affording relief to gardeners when out of employment. A great number of gardeners are always lacking situation for a great variety of reasons, and only too often through no fault of their own; their savings are soon spent, and many are reduced to great straits. It may be urged against such a scheme that it would afford a premium on idleness, but that is not my opinion. It should be made an essential part of the scheme that it should be supported by the subscriptions of gardeners themselves, and that only subscribers should benefit. The subscription might consist of £1 a year, and the amount of relief afforded should be small; say 5s. a week for single men, with 2s. 6d. extra for wife, and an additional 1s. for each child. I am mentioning these figures at random. I leave it to others of greater experience in such matters to say if such a scheme could be made self-supporting. A strict investigation would be made in the district in which an applicant resides, before placing him on the register, so as to prevent undesirable persons joining. I should like to have the opinion of gardeners on this matter; also whether the formation of an entirely new society is desirable, or whether it would be better that the existing societies should take up the matter. Neither should it be looked upon as a scheme for commencing Her Majesty's Jubilee, of which there are already enough; but I feel that no harm can be done in stating the needs of self-help for gardeners in this very important matter. *L. F. P.*

GRAPE GROS MAROC AND OTHERS AT EDINBURGH.—In reply to the person who called himself a "Northern Gardener," who asks why I did not write "sooner about the judging of Grapes" at Edinburgh, may I remind him that if he had read the recent numbers of the *Gardeners' Chronicle* he would not have required to ask that question; it was not I who started the topic, and one reason for my taking part in the discussion was that I was asked so to do. I am sorry that my "audacity" has given offence to a "Northern Gardener." I am not, however, sorry, nor do I regret one single word that I have written about this matter, and my contention has already met with support from independent sources. *David Andrie, Leabart House, Parkside, Strathguthrie.* [Enough has now been said on this subject. Ed.]

VICTORIAN ERA FUND.—My suggestion does not meet with everyone's approval. I did not think it would do so; but I still maintain that there are, I should think, very few gardeners, or young gardeners, who cannot afford to contribute the modest sum I mentioned. Therefore, although I quite agree with your correspondent ("Life-member and Annual Subscriber") that all gardeners who possibly can do so, should become annual subscribers, I do not agree with him that young gardeners (by which I mean the young men who live in bothies and cottages in gardens, not the labourers), should not be asked to subscribe. I think there are very few of these who would not give a little to help their unfortunate or aged brethren. From my own experience, I have known young men subscribe, both liberally and freely, on several occasions, and I think they would do so again. Since writing my last letter, I have looked over the *Victorian Era Directory*, and taking a rough average of three in each garden (one at each scale), I find that such a subscription would realise the handsome sum of over £5000. This is surely something worth trying for, and yet within the reach of nearly all to assist in obtaining. *F. Harris, Eastnor.*

CEADARS OF LEBANON.—Your correspondent, "A Traveller" (*Gardeners' Chronicle*, p. 145), makes enquiries as to seminal variation of *Cedrus Libani* observed in their native habitats. Of that I know nothing, but it is quite certain that among the fine specimens of the tree in this country there are several types which are distinct, both in habit of growth and colour of the needles. A week ago I visited Highclere Castle (Gardens) and viewed the famous Cedars of Lebanon at that place. Mr. Pope, the gardener, pointed out to me two distinct types of Lebanon Cedar, an erect-growing variety of a deep shade of green with very massive limbs, but with a very short trunk. The other type is of a pendulous growth, and foliage of grey-green, and although seeming to lack the vigour of the erect, growing variety, it has a much finer trunk, clean and straight, such as might have furnished the fine timber of antiquity, as the pendulous habit would prevent the lodgment of the heavy snows of the Lebanon region. There is still another type with an erect habit, and needles of a glaucous blue colour, nearly the same shade as those of *Abies nobilis*, but the tree is not so large as either. Of this type are some very fine trees at Whiteknights Park, Reading. It would indeed be interesting to know if anything has been done to protect the grove of Cedars of Lebanon, bearing in mind that they are of great interest to all civilized nations, and since Palestine and Syria are among the much-visited countries of the east. The wealthy tourist might undertake to do what the Patriarch of the Maronites may be too poor to effect, and would be a worthy object for which to solicit subscriptions to protect these trees which are memorials of so many poetic illustrations in Holy Writ. *R. M. Newbury.*

SOCIETIES.

NATIONAL DAHLIA.

The following is the Report of the Committee for the year 1896. If the number of Dahlia blooms, especially of the Cactus varieties, exhibited at the National Dahlia Society's Show at the Crystal Palace, in London, in February, 1896, was less than usual, the fact is to be attributed, not to any diminution of seed on the part of Dahlia growers, but to the abnormal nature of the season. An almost rainless spring and summer effectually prevented Dahlia plants from making their natural growth at the usual time, even where the plants were well watered; and then, the rain coming just when the plants should have been coming into bloom, they started into growth so vigorous that it seemed likely to postpone all flowering indefinitely. Immense Dahlia plants, notably in the Cactus and decorative sections, were quite "green" at the time of the society's exhibition, at which, in consequence, some of the largest growers were unable to compete. If, however, the extent of the show was below the average, the flowers that grew of good quality; and the new class for "vase decoration" was generally considered a success and an addition to the exhibition. The same, however, can hardly be said of the new classes for "Cactus and amateurs not employing a gardener"—classes for which Messrs. Donnie & Co. kindly presented the prizes. The plan in forming these classes was to attract to the society's exhibition new competitors or beginners in Dahlia-culture; but the prizes were won in competitions with the old hands, and the prizes were in some cases, and who at the same time were taking prizes in some of the largest classes. For another year, therefore, it

would probably be more useful to make two similar classes for "competitors who have never before won a prize at an exhibition of the National Dahlia Society."

The committee desire to convey their thanks to the donors of special prizes; and also to the officers of the Horticultural Club for their permission for holding the society's meetings in the club-room.

The committee deeply regret to have to record the great loss sustained by the society through the death of their President, the Rev. Charles Fellows, who was elected to the presidency in 1888, and had continued to occupy the post to the last. [Mr. Fellows' achievements were dealt with in these pages on December 26, 1896, p. 790. Ed.] The committee also deplore their loss, by death, of Mr. F. FULL of Tottenham.

The income of the society from all sources, including the balance of £413s. 5d. in the society's favour from the year 1895, amounted to £142 19s. 1d.; and the entire expenditure, including the payment of all prizes awarded at the Crystal Palace, amounted to £144 8s. 9d., leaving a balance in the society's favour of £28 10s. 4d. The Annual Exhibition will this year be held at the Crystal Palace on Friday and Saturday, September 3 and 4, 1897.

With a view to commemorating the auspicious event of the Queen's reign having proved the longest on record, various new classes have been added to the schedule, including especially "The Commemorative Class" (class 1), designed to display the work of the best British artists of the last sixty years. The Hon. Secretary of the Society is Mr. J. F. HUDSON, Gunnersbury House, Acton, W., and the Hon. Treasurer, E. MAWLEY, Esq., Rose Bank, Borkhamstead, Herts.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

A recent fortnightly meeting of this Society was held in the Club Room, British Workman, Reading, when Mr. T. NEVE presided over a very large attendance of members. After the usual business had been disposed of and five new members elected, Mr. P. H. FORTKES, B.S. Edin., of the staff of the University Extension College, Reading, gave an interesting and practical lecture on "Insects Injurious to Plant Life."

Mr. Fortkes in opening his subject dealt with the great damage done annually by the various pests, and drew attention to the fact that the annual loss to the country runs into hundreds of thousands of pounds sterling. In instancing some of the most noticeable pests, he quoted the Hop aphid as doing damage in one year to the extent of £500,000. Besides true insects, there are a number of pests which do a great deal of damage, the most noticeable of which are the earthworm and red-spider. Passing on to the distinguishing features of insect attack, he dwelt on the different stages of an insect's life, how in some cases the damage is done in the larval or grub stage, in the mature stage, and in some cases insects are capable of doing damage in both stages. Of the rarer kinds of attack there are those insects which attack the seeds, flowers, the seedling leaves, and the mature leaves; those which live on the roots and underground stems; and also those which live in the stems and boughs of trees. Reference was made to the conditions which are essential if the various stages of insect life are to be successfully prevented, and conditions which are just as much required as these are necessary for the germination of seeds. Of these, shelter, suitable food and warmth were most requisite. This fact that insects are not so lowly organised as is generally believed was shown by the statement of Litter as to the presence of certain organs of scent of many insects by means of which an insect can detect its food a long distance off; hence insects often make their appearance on a field after weeding and thinning of a crop, the bruising of the plants resulting in the operation causing them to give forth a smell which no doubt attracts the insects. The lecturer then dealt with the resemblance of fungoid growths to the results of insect attack, and showed this more clearly by throwing on the screen some photographs of Swedes which had been attacked by "finger-and-toe," and Swedes which had been attacked by the "Turnip-mill beetle." The habits of insects as to appearance and time of feeding were also dwelt upon, as well as the manner in which an insect fed. Passing on to the types of insects, an account of the life-history and habits of the winter-moth was first given. No insect is a better example than this one of the value of knowing the habits and characteristics of a pest when all the measures for prevention and remedy of attack. In this case it is known exactly when the moth will appear, when and where the eggs are laid, and when the caterpillar will come out to do the damage. Knowing these features, the gardener was in possession of valuable facts which he could make use of to overcome the pest. Passing over the various measures adopted, he showed, by the aid of the lantern, a useful form of moth-guard for preventing the female moth climbing up the trees to lay her eggs. The earth-worm was next taken as a type of garden pest, pictures were put up on the screen showing the attack on Cucumber and Tomato roots as well as the various life stages of this pest. In dealing with the measures of prevention and remedy, he instanced, among others, the use of "capture" plants as a means of clearing the ground of the earthworm, a practice which has been adopted in Germany on a large scale with considerable success. In concluding, the lecturer said that though we

knew the habits and characteristics of a number of our pests, yet there was a great deal of information still to be learned, and he pleaded for the help of those who by their natural habits and calling were continually coming into contact with insect pests. A number of questions were asked as to the chafers, Vine-weevils, crickets, &c., and an interesting discussion followed.

Among the exhibits were Princess Beatrice, Gloire du Bourg Violeta, a perfect head of flower of a hybrid Chivein, raised by Mr. BIRCH of Whitechapel; and a "blue" Primrose; whilst an excellent display of insects injurious to plants, seeds, trees, &c. were exhibited by Mr. H. HAM of the Reading Natural History Society. A hearty vote of thanks was accorded to Mr. FORTKES for his lecture, and to those who had brought the flowers, &c. for the inspection of the members.

Obituary.

JAMES SALTER, F.R.S.—We regret to hear of the death at Basingfold, Basingtoke, on the 28th ult., in his 73rd year, of Samuel James Augustus Salter. Mr. Salter held a foremost place in medical and scientific circles some years ago, and since his retirement to Basingtoke occupied himself largely with horticultural matters. A short article on planting on chalk soils, originally contributed to this journal, has "gone the round" ever since, sometimes with, sometimes without acknowledgment. Mr. Salter was the first to make the remarkable observation of the occasional formation of pollen-grains within the tissues of the ovule in Passion-flowers as recorded in the Transactions of the Linnean Society. He was a man of extensive knowledge, and an acknowledged master in some departments, and this fact, accompanied by great amiability, endeared him to his friends. Mr. Salter came of a family remarkable for their attainments. Among his brothers were Dr. Bell Salter of Ryde, well known in botanical circles, and the late Dr. Hyde Salter, an eminent London physician.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees.—"11°-degree" signifying 11 continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Table with columns: DISTRICTS, TEMPERATURE, RAINFALL, BRIGHT SUN. Rows include districts like Scotland, N.E., and various weather data points.

The districts indicated by number in the first column are the following:— 0, Scotland N. Principal Wheat-producing Districts— 1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S.; 6, Principal Grazing, &c. Districts— 0, Scotland, W.; 1, England, N.W.; 2, S. England, S.W.; 3, Ireland, N.; 7, Ireland, S.; 8, Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending February 27, is furnished from the Meteorological Office:—

"The weather during this period was generally fair and dry in all the more southern parts of the kingdom, while in the extreme north an E. or N.E. wind fell on almost every day, the falls being very large in the North of Scotland. "The temperature was much above the mean, the excess ranging from 4° in the 'Channel Islands' to 8° in the 'Midland Counties,' 'England, E.,' and 'Scotland, E.,' and to 9° in 'England, N.E.'" The highest of the maxima, which were recorded either on the 2nd or 3rd, ranged from 64° in 'Scotland, E.' (at Aberdeen), and 69° in 'England, N.E.,' to 55° in 'Scotland, W.,' and 'England, N.W.,' and to 54° in the 'Channel Islands.'" The lowest of the minima were registered on the 4th, when they varied from 31° in 'Scotland, E.,' the 'Midland Counties,' and 'Ireland, N.,' to 29° in 'England, S.,' and to 27° in the 'Channel Islands.'" "The rainfall exceeded the mean over Scotland, and the north of Ireland, the excess being large in 'Scotland, N.,' and 'W.,' in 'England, N.W.," the fall just equaled the normal, while in all other districts there was a deficit. At some of the south-eastern and southern stations the week was quite rainless. "The bright sunshine was deficient in most parts of the kingdom, but exceeded the normal in the eastern and north-eastern districts. The percentage of the possible duration ranged from 33 in 'England, E.,' 33 in 'England, N.E.,' and 31 in 'Scotland, E.,' to 23 in 'England, S.," 12 in 'Scotland, N.,' and 10 in 'England, S.W.'"

ENQUIRY.

"He that questioneth much shall learn much."—BACON. TERRESTRIAL ORCHIDS AND JAGO FIBRE.—"A. B." asks for information from anyone who may have tried the fibre for the growth of terrestrial Orchids.

POTATOS.

Trade very stagnant, and stocks still increasing. Dumber Maincrop, 85s. to 90s.; do., Saxons, 85s. to 78s.; Lincoln Maincrop, 40s. to 70s.; do., Saxons and Abundance, 35s. to 70s.; do., Giants, 35s. to 55s.; do., Saxons, 30s. to 55s. *John Bath, Wellington Street, Covent Garden.*

SEEDS.

LONDON: *March 3.*—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pool, Borough, London, S.E., say that notwithstanding the recent heavy rains, which delay farming operations, there is now as might be expected, a daily increasing demand for Clover and Grass seeds. Buyers find this season that their requirements can be satisfied on very moderate terms. Lucerne and Sainfoin are in good request. There is no change in Tares. Canary seed is firm. For Peas and Haricots, but quantities prevail. Rape seed tends upwards. Mustard unaltered. Linseed steady.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending February 27, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1896.	1897.	Difference.
Wheat	s. d. 25 6	s. d. 28 2	+ 2 8
Barley	s. d. 21 10	s. d. 23 8	+ 1 10
Oats	s. d. 13 10	s. d. 16 3	+ 2 5

ANTS: *Artus.* Use carbolic acid in their haunts and set saucers filled with treacle about, with some means afforded the ants to climb into them.

ASPARAGUS FLOREUS: *C. E. W.* A. p. nans, if true, to name, is merely a variety, and like the type, may be increased by division of the roots, and cuttings of the half-ripened shoots, struck in bottom-heat, and possibly from root-cuttings. Seeds are obtainable, but these could not be depended upon to produce the true form of the plant. You are employing more heat by night than is required. Before we can tell you if you have the true plant, you should send a plant, or piece of one, for observation.

BOOKS: *J. H. G.* Botanical Dictionary by Thomas Martyn, B.D., F.R.S., 1784. Professor of Botany, Cambridge University, published 1790. A well-known book. Valuable only as a curiosity. Try the second-hand book-sellers.

CRITICISM OF GARDENER: *H. W.* So long as your employer is satisfied with you, it will not greatly matter what the visitor says about your methods.

FLOWERS FROM SEED IN COLD CONSERVATORY. *T. F.* Antennas: **Acroclitium rostratum*, **Aloxosa lunifolia*, **Globe Amaranth*, **Amaranthus*, **Hemlock*, and others: **Asters* of all kinds, especially the tall varieties: double flowered Balsams, tuberous-rooted

Begonias, **Calceolaria herbacea* (for flowering next year), *Canary Creeper*, *Celosia pyramidalis*, *Cineraria* (for another year), *Colens* in variety, *Eccremocarpus scaber* (climber), *Lobelia ranosa*, *Martynia fragrans* and others, *Murandiya Barclayana* (climber), *Melanthus major*, **Mignonette variegata*, **Scytanthus*, tall (climber) and several varieties: **Nemesia contraria* in variety, *Potunius*, *Rhodanthe Manglieii* and *R. maculata*, *Ricinus Gibsoni* (foliage plant, copper red leaves, nice grown in pots), *Scyphanthus elegans*, *Ten-week Stocks*, and other annual varieties; *Thunbergia alata* and others; and *Verbena* in variety. In addition to the creeping plants already given, mention may be made of *Lophospermum scandens*, *L. atro-sanguineum* (*Rhodochiton volubile*), and *Cobaea scandens*. With the exception of those marked with an asterisk, these seeds should be sown in pots placed in heat, pricking them out into other pots before they spoil by crowding each other, and growing them on near the glass, and with good ventilation in mild weather. The chief thing to guard against is weak etiolated growth. Annuals need rich soil, well decayed manure, not too much drainage material, and but few plants, or as in the case of creepers, Balsams, *Celosias*, *Ricinus*, only one plant in a pot. Of the shorter lived plants it will be well to make two swings, one late in March and one in the beginning of May. In the case of Balsams, if some of these plants are kept in pots of 6 to 8 inches diameter, and all the flowers allowed to remain, they will give an early display; for later flowering the blooms must be removed until the plants reach the desired size, and one or two large shifts given.

GARDENERS' ROYAL BENEVOLENT. *T. S. E.* It is next to an absolute certainty that a subscriber for the allotted period will, if he be in need, receive the benefit without the trouble of election. Practically, it is certain, but to meet exigencies which might by some extremely remote possibility arise, it is desirable that the right should be ratified at a general meeting. To those who become life-members it is by far the cheapest investment we know of. The only element of chance in it is that some may never want to avail themselves of the assistance of the fund, whilst others will. The former have the satisfaction of knowing that they are contributing to the welfare of their brethren, the latter, as we have said, are certain to be elected if they have complied with the rules.

GREENHOUSE, AND RENT FOR THE SAME. *T. B.* What can you expect to put up a greenhouse on land that is merely lent to you, but that the owners will make you pay rent for it or pull it down. Rather advise to spend your money in doing this when the tenancy is so precarious. You had better consult a solicitor about the other matter of which you write.

INSECTS: *A. B. S. H.* The grubs sent with *Wallflower* are those known as the wireworm grubs of the *Click-beetle*. They are most destructive to very many kinds of vegetation, and they are difficult of eradication. Lime and salt are both employed with advantage to infested land, and an application of gas-lime in its caustic state is one of the best methods of treatment. The burning nature of this, however, necessitates the operation being done in autumn, and no crops should be put upon the land until late spring. See also article on **Mustard and Wireworms* on p. 150.

INSECTS IN VINERY: *W. H. W.* The name of the beetle is *Triox sulvulosus*. They are not likely to injure the Vines, and were probably introduced with animal matter (bones?) used as manure. Nevertheless, they are, no doubt, a nuisance, and should be got rid of as such. *R. M. L.*

LEGUMINE CHLORIFORM. The plant growing in the grounds of the Atkinson Morley Convalescent Hospital, Wimbledon, and mentioned by *J. Colercock* in our issue of February 20, p. 128, is, as the writer of the note informs us, *L. ovalifolium*.

MILDEN ON TEA ROSES: *C. N. May.* Dusting with sulphur vivum (black sulphur), or failing that, the ordinary flowers-of-sulphur. The sulphur when used in a dry state should be applied when the leaves are wet. Sulphur may be mixed like mustard, till it is well incorporated with a small quantity of water, and then diluted with 15 to 20 parts of soap-suds, and applied with a syringe fitted with a nozzle. Two or three applications on alternate days are required to get rid of mildew. When a few leaves or shoots are affected, it is better to apply sulphur in the dry state with a

small dredger or pepper-box. The florists sell mildew destroyers, but we are not aware that these are better than sulphur. Be careful in ventilating the house in which are the Roses, keeping it moderately warm and the air in motion, and admitting for the present, air at the bottom of the house, unless it can be warmed by impinging in its passage into the house on the hot-water pipes. Coat these pipes with linewash, having a considerable proportion of sulphur mixed in it.

NAME OF FRUIT: *J. P.* Pear, Knight's Monarch.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—M.* Your specimen was mislaid, but has now been found. We regret the delay in replying to you. The plant is probably *Thuya (Chiloid)* Sieboldi of gardens—*Constant Bealer*. The Orchid is a very large and fully-coloured *Cattleya Trianae*; the other plant *Columnnea hirsuta*. The Violets are very fine—*A. R. S.* 1, *Pellionia pulchra*; 2, *Pellionia Davaeana*; 3, *Selaginella denticulata*.—*J. H.* **Tagasate*, **Cytinus proliferus* from Canaries. Recommended as a fodder plant for some countries. See *Kew Bulletin*, 1891, 239.

ORCHIDS: *J. E. D.* We do not know of any plant called *Oncidium Bungeana*, imported by Lindley, nor any *Prassia splendens*-ina. The former may possibly be intended for *Oncidium Bungeorthi*, imported by Linden, but we find no such name in our records.

PEACH TREES IN UNHEATED HOUSE: *T. F.* Having glass protection only to preserve the blossoms from injury from frost, it will be prudent to keep the house cool and well ventilated so as to retard the expansion of the flowers to the latest date. As a rule for general observation, do not wet the trees or make the soil in any moist till fruit has set, and the weather gets warmer. When there is no longer any danger from frost, the trees should be syringed night and morning in fine weather, doing less of it in dull and rainy weather. You have done what is right in keeping the borders moist.

PETROLEUM BARRELS. *J. W. G.* Kettle a fire with straw, &c., inside each, and when the staves are slightly charred, and the oil with which the wood was saturated is in part consumed, put out the flames by cutting off the supply of air, and then soak the barrels in water for a few days. The oil remaining in the wood after this sort of treatment is not likely to injure Peach or other fruit trees planted in the barrels.

PRUNING CURRANT BUSHES WHEN PLANTED: *H. W.* It is the usual practice, and the Currant does not resent it, so far as to put an accession of roots to possess a large quantity of roots in proportion to its size, so that the growth during the year of planting is sufficient to give the rudimentary framework of the future head, even when pruned. If roots were scanty, it might be better not to cut at all the first year, but encourage leaf growth, as this would lead to greater root extension; and what pruning was required might take the form of disbanding in May or later, according to the state made.

QUITTING SERVICE WITHOUT NOTICE: *Pteris.* As a weekly servant, a week's notice is required from employe or employer under ordinary circumstances.

STACHYS TUBERIFERA SYN. CHINENSIS, AND CHINESE ARTICHOKE: *H. E. C.* This plant has nothing whatever to do with Solomon's Seal. It is a misprint of *or for and*, in the top line.

COMMUNICATIONS RECEIVED.—F. H. *Henry Thacker*, L. L.—*Frank W.*, Vermont—*B. C.* *an*—*R. G.* *The Plants* *Kibi*, Japan.—*Born*, *E.*, *Flouche*—*R. A.*, New Orleans.—*C. CONVINCED LARVA INSECTS IN THE CIRCULATION OF THE "GARDENER'S CHRONICLE" *The Publisher has the satisfaction of announcing that the circulation of the "Gardener's Chronicle" has, since the reduction in the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly. Advertisers are invited to take full advantage of this opportunity, and all classes of GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is prepared for reference to all the principal Libraries.*

THE

Gardeners' Chronicle.

SATURDAY, MARCH 13, 1897.

STREET TREES.

HARDLY more than sixty years have passed since the Champs Elysées were truthfully described as impassable by day on account of the bad state of the roads, and by night by reason of the hosts of vagrants that frequented them. For many years past, thanks largely to improved sanitation and the planting of street trees as a science and an every-day practice, Paris has become assuredly one of the fairest, safest, pleasantest cities in the world. Not by any means that its Seine or its slums are without spot, or perfect. But its street-planting, its parks, its open places, are magnificent. Many of the public roads in the rural districts of France and the main streets of Paris and other great cities are open spaces on a regal scale. There may be, there are sanitary blemishes in France. But every great highway is a ventilator and a purifier, a utiliser of the waste products of life and labour. We are often told in this country that land is too valuable to be spared for the growth of trees in our great cities and towns. But "where there's a will there's a way." Land in France is so much and so severely sliced up by law and custom as to create a land-hunger that is daily growing more intense in its severity. And yet in the Champs Elysées, in the centre of Paris, room has not only been found for one avenue, but for five or more, with flower-gardens and shrubberies thrown in as well. And thus it comes to pass that no one can look for the first time down the Champs Elysées from the Arc de Triomphe to the Place de la Concorde, and ever forget the grandeur and beauty of the sight. Is it a wood, a park, a garden, or a city? It is all four. Much that is far from perfect in the life of this fair city is hidden from view under the thick veil of trees, shrubs, and flowers. With the exception of the Palais de l'Industrie, which earns a large rental to the Municipality, but which is soon to be removed, there are few other substantial buildings among the trees or gardens, and yet the rental for pleasure gardens, refreshments, chairs, theatres, &c., amounted to £11,000 in 1895. The thousands of coloured lamps, which seem immensely popular with visitors and the Parisians, add a weird-like charm to the trees, without revealing much or many of the flimsy buildings hidden away among them. But by planting such grand avenues as the Champs Elysées, the Bois de Boulogne, the Avenue de la Grande Armée, the Boulevard Beaumarchais, the Boulevard Richard-Lenoir, and scores of others almost equally long and spacious, tree-planting has been firmly established as one of the most important functions of the municipality of Paris, and is prosecuted

with a skill and an energy almost unknown to us in this country.

It may now be taken for granted that almost any of our deciduous trees will grow and flourish if sites, soils, and sorts are carefully selected, planting and culture skilfully effected, and adequate care taken in after maintenance.

In planting in fresh towns and districts, however, it is best to proceed tentatively, taking careful notes of those trees in the district that soonest grow into things of beauty and last the longest. There is one more caution that needs to be given to any that may be fresh from Paris. Few are likely to be able to plant other cities in the grand style of that fair city. The majority of the main streets and boulevards of Paris are from 100 to 150 feet from house to house. As much as 40 feet is at times devoted to the centre avenue, with 25 feet on either side to side-walks or pavement. And then large spaces are often devoted to flowers, shrubs, and masses of small trees and shrubs. In fact, such avenues as that of the Bois de Boulogne, that links together the Arc de Triomphe and the Bois de Boulogne, is as much, or more, a series of gardens, as a magnificent avenue in grand luxurious style.

Something on a much humbler scale would suffice for the majority of our towns in this country, not that any street-planting can be too good for London, Edinburgh, Glasgow, Dundee, Manchester, Birmingham, &c.; still, a great deal may be done to fringe almost interminable lengths of brick and mortar with refreshing verdure and beauty. The designers of new Edinburgh deserve high credit for their bold and capacious planting between their massive blocks of buildings in their squares. Another charming transformation scene was the evolution of the Prince's Street gardens, from what was virtually a public nuisance. Other and almost equally valuable improvements have been effected in the vale of the Eden, and in many other directions the area of verdure and beauty is extending.

The Royal Botanic Garden, which is now open to all, has long been a centre of light and leading in horticultural matters, and seems greatly prized. Edinburgh has also long been famous for the extent and excellence of its nurseries of fine trees and shrubs. It has also long been the home of the Royal Scottish Arboricultural Society, which exists to foster the love of all that is best and most beautiful in trees and shrubs. And yet the majority of the streets and main thoroughfares of Edinburgh are treeless, or nearly so. The very massiveness and coldness of its stone architecture make matters worse. The paucity of trees gives a feeling of coldness, an air of stiffness and hardness to the towering architectural magnificence of Edinburgh. The life, the mobility of trees; the grace of climbers, the glowing colours of foliage and flowers, are needed to soften and enrich the half-faced monotony of miles and miles of grey walls, uprising from the lowest depth, and losing themselves in the dizzy heights of Scotch mists that rest in cloud land. Public and private buildings, castles, monuments, mountains, constitute a sombre study in grey, that cry out loudly for relief. Fortunately, Prince's Street and most of the main thoroughfares in the new town of Edinburgh, and not a few in the old, are sufficiently wide for double lines of trees, thus converting the stiff, stately streets into avenues as graceful as grateful. The lop-sided spaces

could readily be converted into charming avenues, while, at the same time, multiplying manifold their shelters, shadows, colours, variety, and beauty. F.

ORCHID NOTES AND GLEANINGS.

CATTLEYA TRIANÆI.

THIS fine form of *C. labiata* has been beautifying our gardens during the protracted dull weather, and the gorgeous colours and innumerable varieties should render it a close rival to the autumn-flowering form. But two things militate against *C. Trianæi* being the general favourite; it should be, which, are, that in the first place, unless it is imported from a known good quarter, an overwhelming proportion of poor varieties is found among them; and in the second place, it should naturally flower in the dead of winter, but from the absence of light and sun during most winters, the bulbs have to take so long in perfecting that they cannot show themselves to advantage. A box of really grand flowers sent by Joseph Broome, Esq., Sunny Hill, Llandudno (agr., Mr. David Boardman), tells of a better light and a purer air than fall to the lot of plants grown near large towns. The flowers in every instance are large and broad-petalled, and three of them well simulate three good varieties of other sections of the species. One has showy flowers, and expanded frilled lip, like *C. Mendeli*; another is a good representation of a dark *C. labiata* Warreri; and the third has light rose sepals, petals, and tube to the lip, whose broad front-lobe is coloured like *C. Warszewiczii*, even to the two yellow marks, one on each side of the tube. J. O'B.

DENDROBICH NOBILE NOBILIUS.

In an importation of some 2,000 or more Orchids last year, we had at least ten plants of this very pretty variety, some of which are now in flower. It is something like twenty years ago since *D. nobile nobilius* first flowered in this country, and even now it is not by any means common. When the plants are arranged among other species of Orchids, it shows to great advantage. Although I should think that it would succeed when grown in baskets, suspended from the roof, we have been very successful with it in orchid-pots. *D. n. nobilius* requires the heat of the East Indian-house when making its growth, and plenty of water at the roots, but only enough to prevent shrivelling of the bulbs when at rest, at which time it should be in a lower temperature, but not one that is below 50° Fahrenheit. If it be kept when in bloom in a cool airy house, the flowers will last in perfection for about six weeks, but they must be shaded from the sun's rays. G. Barsons, Brick Gardens, Stroudsburg.

CALADIUMS.

THE Caladiums grown as decorative plants are, many of them, descended from the well-known *Caladium bicolor*, Ventenat. The beautiful *Caladium argyrites*—a synonym for *C. Humboldtii*—is, however, distinct from *Caladium bicolor*, Vent. Both of these species thrive well under the conditions which obtain in and around the district of Trinidad in which the Botanic Gardens are situated, and are easily cultivated. The varieties of the first mentioned species are very numerous, and have long been great favourites with both the amateur and professional gardener. It is singular, however, that while the first species has produced innumerable varieties with parti-coloured or tri-coloured leaves, *C. Humboldtii* has remained true to the original type. The amount of variation in the individual varieties of *Caladium bicolor*, when grown in Trinidad, is however but little marked when under cultivation; but on the contrary, it is to be noted that where the plant has been cultivated and has been planted into the soil of the garden, there is exhibited a distinct tendency to revert to the original *bicolor*, or to one which has nothing more than a green leaf—the shape, size, and

habit of the original bicolor, but without coloration of any kind. In the Botanic Gardens so much is this the case, that in many corners, on the lawns and in various other places, plants of *Caladium bicolor* can be seen growing vigorously among grass and other plants, which have lost all or most of the reddish colour in the centre of the leaf which is common to *Caladium bicolor*. The same plant may also be found quite common on many Cacao estates, where it has escaped from cultivation, growing freely under the shade of the Cacao trees. It may also be plentifully found along banks and on the roadsides in villages where it has escaped from gardens. *Caladiums*, with home cultivators, are sometimes difficult things to grow. This arises, for the greater part, from the inattention which they receive when their beauty begins to fade. The *Caladium* requires plenty of heat, a temperature from 90° Fah. to one not lower than 65° Fah. being best suited to its growth. When its tubers are matured, and the leaves commence to turn yellow, it will stand a long period of drought; but if the dry weather sets in before full growth is made, the tubers are apt to rot, and they will not keep good in a low temperature. These acts are the key to good cultivation. As much, or more, care and attention is required when the plants have lost their beauty, as when they are in full growth and vigour, and those home cultivators who attend to this point and give them plenty of heat all the year round, plenty of water when growing, and a dry warm storage when at rest, will not fail to have *Caladiums* in perfect health and vigour. *Caladium argyrites* does not require as much rest as *C. bicolor*, but it benefits by being accorded a short period at the proper season of the year. *J. Hart*, in *Bulletin, Royal Botanic Gardens, Trinidad*.

PARIS.

(From our own Correspondent.)

NATIONAL FRENCH HORTICULTURAL SOCIETY.

A SPLENDID show of Orchids was the chief feature of the last meeting in Paris. Orchids are decidedly gaining a foremost place here as well as in England and in Belgium, and the number of growers and amateurs steadily increases. M. T. Leroy, gr. to Baron de Rothschild at Armatravilliers, staged *Cymbidium eburneo-Lewianum*, flowers cream-yellow, very fine; *Lælio-Cattleya Leroyana* (*C. gigas* × *L. purpurata*), with very large flowers, fine broadly open pale lilac lip, *Odontoglossum Leroyanum*, a specially interesting hybrid; *O. crispum* × *O. luteo-purpureum*, with numerous large brown spots, the plant having two large spikes. Many other very important groups were shown by M. O. Doin, M. Bert, M. Page (gardener to M. Lebandy, at Bougival), Mr. Dugger (gardener to Madame Halphen, at Ville d'Avray), M. Peeters, and M. Truffaut of Versailles, who had a very important lot of *Cattleya Trianae* in fine varieties. The most interesting plants noticed were *Cypripedium insigne* Sanders, exceptionally fine; *Miltonia Bleuana* aurea; *Pleurothallis Roezlii*. A vermilion-coloured *Epiphrasia* × *Veitchii*, contrasted agreeably with *Lælia anceps* Williamsii, pure white. A specimen of *Sephoronia grandiflora*, with seventy open flowers, was much admired; so was a group of *Cypripedium Sallieri* Hyeannum, *C. Rothschildianum*, *C. niveum maximum*, *C. Lathamianum*, extra fine. A curious plant, *Stenorrhynchum speciosum*, was also remarked; many other good varieties were to be seen, but the space you can allot me would not be sufficient to enumerate half of them; however, we must mention the splendidly-grown *Cypripedium Lebandyannum*, the *Cattleya Trianae* alba, and *Lycaste limipes*, of Mr. Page.

A very important horticultural congress is to be held during the next Paris show in June. Amongst many interesting questions to be discussed, we notice the two following:—"Study of the Causes of the Degeneracy of *Cattleyas* grown in Europe;" "Study of the Influence of Selection: 1. In Raising of Plants from Cuttings; 2. In Raising of Plants from Grafts."

POLYCARPIC AGAVES.

The following notes on the flowering peculiarities of some Agaves, have been prepared at the suggestion of Mr. J. G. Baker, F.R.S. They relate to plants cultivated at Kew, where the collection of living Agaves is a fairly strong one, 90 species of the 138 species admitted by Mr. Baker in his *Handbook of Amaryllidaceae* (1888), being represented there. Since the year 1880 twenty-five species have flowered in the Succulent-house, some of them for the first time in cultivation; others were previously unknown to botanists.

It is popularly believed that all Agaves flower once and then die. This is true of some of them, but not all. Dr. Engelmann in his *Notes on Agaves* (1875), says:—"The majority of Agaves are caulescent and monocarpic (flowering once); the short subterranean trunk continues to grow for years until vigorous enough to evolve the flowering-stem, a continuation

flowered. *A. lurida* var. *Jacquiniana*, as figured in the *Botanical Magazine*, t. 5097, has a trunk 1½ foot long; and *A. rigida* elongata in the Kew Museum has a trunk 1 foot long. Both of these are monocarpic.

The following list comprises the species that have flowered at Kew since 1880, with the year of flowering. Those marked with an asterisk have proved polycarpic:—

* <i>A. albicans</i> , 1891	<i>A. horrida</i> , 1889
<i>A. americana</i> , several	<i>A. Kerchoviæ</i> , 1895
<i>A. atrovirens</i> , 1888 & 96	<i>A. Kewensis</i> , 1895
<i>A. attenuata</i> , 1880	<i>A. laxifolia</i> , 1896
<i>A. Basteri</i> , 1885	<i>A. lobothuta</i> , 1887
* <i>A. Bouchei</i> , 1896	<i>A. multinata</i> , 1887
<i>A. Celsiana</i> , 1894	* <i>A. polyacantha</i> , 1895
<i>A. chloroacantha</i> , 1882	<i>A. chloroacantha</i> , 1894
* <i>A. dasylirioides</i> , frequently	* <i>A. Sartorii</i> , frequently
* <i>A. densiflora</i> , 1894	* <i>A. Scoulyana</i> , 1887
* <i>A. Hemetiana</i> , 1893-88	* <i>A. striata</i> , several
* <i>A. Hasselii</i> , 1894	* <i>A. univittata</i> , 1881
<i>A. Hookeri</i> , 1889	

It is noteworthy that all the species here marked as polycarpic belong to the sub-genus *Littrea*, in which the flowers are borne in pairs, forming a dense subspiculate inflorescence. In the sub-genus *Euaगे*, typified by *A. americana*, the flowers are in clusters placed at the ends of the branches of a deltoid thyrsoid panicle. So far as I know none of the *Euaगे*s are polycarpic.

The thickness of the flower-spike or pole in *Littrea* is much less than that of the stem or trunk of the plant from which it springs. This is shown in the accompanying figures. In *Euaगे*, on the contrary, the pole is about as thick as the trunk. This difference may account for the development of lateral growth-buds after flowering in the plants of the one group and not in the other, the energy of the plant being less heavily taxed by the comparatively smaller inflorescence.

The only species known to develop the inflorescence laterally is *A. Sartorii*; in all the others seen the spike or "pole" is terminal, and in the monocarpic species it ends the life of the plant. In the polycarpic species, a number of lateral buds are formed just below the base of the pole, and one or more of these buds develop and continue the life of the plant. In fig. 47 we have an example of—

A. Bouchei, in which this habit is clearly seen, the production of a flower-spike being followed by the development of a growth-bud, which in its turn flowered, and so on until this year, when the flower-spike was succeeded by two growths, both of which have been removed. Fig. 48 represents a section of the stem of the same species, showing the position of the first lateral growth, *c*. Dr. Engelmann observed this character in a plant in the Berlin Botanic Gardens in 1869.*

A. albicans.—The plant that flowered in 1891 was figured in the *Botanical Magazine*, t. 7207. It lived after flowering, developing two lateral growths, which were removed and planted separately three years ago. In the *Gardeners' Chronicle*, in May, 1885, Mr. J. S. Corderoy noted a similar case which occurred in his garden, both the type and the pretty variegated form of it, known as *albo-picta*, having flowered and developed side growths. He called his plants *A. Ousseigheimiana*, a synonym of *A. albicans*.

A. Celsiana.—This flowered two years ago, when it had a trunk nearly a foot high. Recently the second growth has been cut off and rooted. Mr. Corderoy stated, in the notes referred to under *A. albicans*, that *A. Celsiana* lived after it flowered with him.

A. dasylirioides.—There is a good figure of this species in the *Gardeners' Chronicle*, June, 1889, p. 804, from a plant then in flower at Kew. It flowers frequently, and is in flower now. In this the flower-spike is certainly terminal. The old leaves live for years after the spike has faded, and after the lateral growth has developed to a large size. The spike is peculiar in being ceriseous and drooping, so that if unsupported it would trail on the ground.

A. densiflora flowered two years ago, the dried base of the flower-spike being still on the plant. The new growth is now a rosette 2½ feet across, on a trunk 18 inches high.

* He also noted *A. chloroacantha* as showing the same character.

FIG. 47.—AGAVE BOUCHEI.

Portion of the stem, showing five successive terminal flower spikes; *a*, position of the last lateral bud; *b*, latest flower-spike; *b*, *b*, *b*, remains of previous flower spikes.

of its axis, and dies after bearing fruit. . . . A few have persistent trunks, sometimes of considerable dimensions; these produce flowers repeatedly, just as the caulescent *Yuccas* do, from axillary branches after a terminal bud has fulfilled its destiny and died." These are called polycarpic.

Probably more species of Agave belong to this second or polycarpic group than has hitherto been supposed. Of the twenty-five species flowered at Kew since 1880, no fewer than nine have proved polycarpic. Some of these have been described as caulescent, and therefore monocarpic. This term, caulescent, does not properly apply to many Agaves for which it has been used, many of them forming distinct woody stems above-ground. Judging by cultivated plants, it would be more accurate to say that the majority of Agaves are shortly caulescent.

The produced trunk is not always associated with a polycarpic habit: for instance, *A. attenuata*, which develops a trunk 6 feet high, dies after once flowering. *A. laxifolia*, also distinctly caulescent, died after it

A. Haseloffi.—This also flowered two years ago. It has a trunk 1 foot high, and one lateral rosette a yard across.

A. polyacantha flowered last year (1895). Most of the old leaves are still on the plant, and it has now a new rosette of about twenty leaves, 1 foot long.

A. Sartorii.—A figure of the Kew plant was published in the *Botanical Magazine* in 1877 (t. 6292), when it flowered for the first time. It then had a "stem 1 foot high, forked dichotomously." It bifurcated again at the height of 4 feet, the stems being now 5 feet high. They show distinctly the scars of

eleven flower-scapes, which occur at intervals of about 9 inches. They also show plainly the lateral position of the inflorescence, the ring-scars on the trunk being only partially interrupted by the base of the flower-spike.

A. striata.—Plants of this have flowered several times lately at Kew, and in no case has the plant died or even lost its leaves in consequence.

Some species appear to develop lateral growths in advance of the flower-spike. Thus *A. Kerchovi* major, lately in flower in the Palm-house, has a distinct trunk 2 feet high, supporting a rosette of leaves 6 feet across, from the centre of which the spike rises to a height of 15 feet. From the axils of the upper leaves three arm-like side-growths have developed; they are 18 inches long, the lower two-thirds clothed with short imbricating leaves, the upper portion being a large rosette of leaves, 13 by 3 inches. These growths are more analogous to the stoloniferous suckers that are developed from the base of the trunk of most Agaves, than to the growths of such as *A. Bouchei*. A large specimen of *A. Botteri* has had its central growth arrested by some cause,* probably the formation of an incipient flower-spike, and two lateral growths have started from near the centre. This species belongs to the Littorea. It evidently has the power of developing lateral buds near the top of the axis.

The basal stoloniferous growths appear to be produced at any period of the plant's existence, and are not in any way connected with the production of flowers. In some cases they are so numerous that quite a colony of plants is formed round the original one, suggesting gigantic Saxifragas. If the growing point of a stolon gets damaged, laterals are readily developed from it, a bud being quite perceptible in the axil of every one of the scale-like leaves which clothe these stolons. They may therefore be utilised for the multiplication of the plant by cutting them into lengths of a few inches, and inserting them as cuttings. In *A. filifera* (fig. 49) these stolons are 2 feet long.

Many Agaves produce a crop of bulbils or plantlets on the flower-spike after the flowers have faded, and generally when the capsules (fruit) have not matured. In some cases, however, both capsules and plantlets have been borne together, though I have never seen a case at Kew. These plantlets are often very numerous. In the species which produces *Sisal Hemp*, *A. rigida sisalana*, this "reproduction by means of pole-plants is very interesting. After the blossoms begin to wither and fall away, buds develop from the stalk below, and grow into small plants. After attaining a size of from 3 to 10 inches, they fall to the ground and take root. They have very great vitality, and develop into stout, strong plants. In cultivation they are much used for planting. A single flower-stalk (pole or mast) will bear from 1000 to 2000 pole-plants. As many as 2500 have been reported. The species is said to have spread over the Florida Keys by means of buds from the poles being driven by the currents of air and water." †

It would be interesting to know if this particular Agave is ever propagated by means of seeds, or if basal suckers and pole-plants only are used. Sometimes the pole-plants do not appear until long after the flowers have faded, and the leaves have withered. Last year the only plant known to exist of *A. kewensis* flowered in the Succulent-house at Kew. It had never produced any suckers, and therefore the production of seeds or pole-plants was anxiously hoped for. Not a single capsule matured, the plant having almost perished and the pole itself turned yellow before any plantlets appeared. Finally, however, a good crop was yielded, and there are now plenty of healthy young plants of this very distinct species of Agave at Kew.

A. attenuata does not push out stoloniferous growths, but develops instead buds about the base of the stem, which, when large enough, deliquesce readily, and fall to the ground, where they take root. H. Watson, Kew.

* Since this was written the plant has pushed up a stout flower-spike.

† The *Agave* of the *C. & L. Encyc.* by A. J. Millard (1896) p. 92.

FIG. 48.—AGAVE BOUCHEI.

The right-hand figure shows the stem B, reduced $\frac{1}{2}$; latent leaf buds at E; lateral leaf-bud developed at C; B, remains of terminal flower-spike. The left-hand figure shows at A, section of stem; D, terminal flower spike; C, lateral leaf-bud.

FIG. 49.—AGAVE FILIFERA; SHOWING STOLONIFEROUS SHOOTS.

THE CULTIVATION OF TENDER ALPINES.

For some years past I have devoted attention, in the Jardin Alpin d'Acclimatation, to the study, which may be called experimental, of the acclimatization of certain tender alpine plants which are considered impossible to grow at Geneva. The results, especially of cultivation in sphagnum, of which I spoke in the *Gardeners' Chronicle* on April 14 and July 11, 1891, are of sufficient interest to be further spoken of here. Last summer, at the Congresses held during the National Swiss Exhibition here about ten times between May 1 and October 15, alpine plants sent from the Jardin Alpin were shown, grown in pots of sphagnum in the full sun, and these attracted much interest. Certain of these plants flowered throughout the summer, and among them were specimens of *Linaria alpina*, of *Hutchinsia*, and even of the beautiful *Houstonia cernua*, which I received from England, and have never before succeeded with. There were 100 pans containing rare and tender plants, all of which I had almost given up cultivating at Geneva, and which I could only try to introduce into our gardens among the Alps. I know that the system of cultivating in sphagnum has been tried in England, consequent upon the two previous articles about it in this paper, and I have learnt from letters and conversation that, in Devonshire and Cornwall for instance, good results have been obtained, but that, in other countries failure has ensued. Evidently there is everything in the influence of warm and dry air, and it is absolutely necessary to experiment only under these conditions. The proof of this is, that, at Nice, Cannes, and Tassin, the system has succeeded well, while in North Holland, as in England, no results have been obtained.

It appears evident to me that sphagnum exercises a mechanical and physical influence very important to alpine plants. It serves as a sponge round their foliage and roots, absorbing damp when that is prevalent, and restoring it gradually to the air or soil when drought begins. This is, as I have before said, the part played on a greater scale by the rocks in nature. Sphagnum is an equalising element; it condenses and dispenses moisture in a valuable way. Its chemical action seems void, as we have grown, in pans and under the same conditions, species very nearly related, and which pass for sand or for lime-loving varieties of the same type, and they have varied slightly. They have completely retained their characteristics; and thus, *Linaria alpina* and *L. petraea*, which are so similar, that one is considered to be an oolitic form of the other, keep up and even slightly accentuate their individual differences at the end of two years' simultaneous cultivation in sphagnum, and I have come to consider them as true and different species. The late Professor Romanes of Oxford experimented on the variability of species, recommended me to conduct my investigations on these lines. We have in our Jardin Botanique de la Linneé, at Bourg de Pierre, planted side by side, species similar in type, but from varying habitats, as *Ranunculus pyrenaicus* and *serbicus*, *Linaria alpina* and *petraea*, *Gentiana Chisii*, *Kochia alpina* and *augustifolia*, *Geranium argenteum* and *cinerium*, &c. But we have not succeeded in preserving their distinctive characteristics so well as with plants grown in sphagnum.

Further, strange to say, plants grown in sphagnum flower more abundantly than when wild; the blooms are earlier and last longer. For instance, I had last year a plant of *Cyananthus lobatus*, which had not before flowered with me, and which, grown in sphagnum, bloomed from May to September. I have now, in my window, three pans of flowers which are much admired; one contains four plants of *Soldanella montana*, bearing, in all, sixty flowers. I have never before bloomed this *Soldanella*. It is, therefore, plainly shown that the use of sphagnum for soil is the best plan for growing and flowering delicate alpine in dry warm climates. Its retention of moisture enables it to supply the lack of that wet and moisture which, in the Alps, is so freely supplied to the plant. I should add, that I have succeeded in blooming the

fine and rare *Diapensia lapponica* by this plan. Last April I had a strong plant in a pot of sphagnum, and it has now borne sixty-eight flowers. This plant is difficult to cultivate, and the seed often remains eighteen months before germinating. It is very graceful, and is elegant when well developed. *H. Corceon*, *Jardin Alpin d'Acclimatation, Geneva*.

LILIUM HUMBOLDTI.

The typical *Lilium Humboldtii* has a large ovoid bulb, more or less oblique, and occasionally prolonged laterally in a semi-rhizomatous manner. The scales are thick, and the bulb very compact. In height the stem is often above 4 feet. I have seen it 9 feet high, and in one instance a single stalk bore eighty buds. Ten or fifteen flowers in a panicle are common. The lower pedicels are longer, and, growing gradually shorter, form a broadly conical panicle. The flowers are large and of much substance, of a uniform rich reddish-orange spotted with maroon, and strongly reflexed. Nature has provided for the weight of the great panicles by giving this Lily a very stout, erect stem, which is well furnished with leaves in full whorls.

In its native home in the foothills of the main Sierra Nevada, *Lilium Humboldtii* usually follows the belt of Yellow Pine (*Pinus ponderosa*), and grows in the open woods. It does not often grow above the 1000-foot line, nor on the lower foothills. Just how far north it extends I have never been able to learn. I know of it in Tehama County, California, but have never seen or heard of in the Mount Shasta region. It has never been reliably reported from any point in the northern Coast Range of California, although I have recently learned of a Lily in Humboldt County which can only be *L. Humboldtii*, or an unnamed species. Neither have I been able to learn of this Lily in the foothills of the lower San Joaquin Valley, nor farther south than the Yosemite road. Generally it is strictly a mountain species, but there is one notable exception in the upper Sacramento valley. Some fifteen years ago it grew sparsely at one location in the Oak forest which borders the river; it is now abundant for 12 or 15 miles along the river. In El Dorado County I saw it flowering to perfection last June. A fire had gone through some second-growth Pines a year or two before, and the magnificent panicles made a gorgeous display high above the Ferns and weeds. The top of the hill had been cleared some years before, and was cultivated in grass and grain, but in the new stubble many stubs of the Lily-stalks could be seen, and from wounds made by the plough the bulbs had been broken into groups of from two or three to a dozen bulbs. The Lilies are evidently on the increase under the conditions, and the bulbs were very healthy. As a cultural hint I would say that *L. Humboldtii* always grows on well-drained soil. The subsoil is usually rocky, the upper soil clayey or volcanic.

In Southern California there are two other strongly marked types of *Lilium Humboldtii*. Of these *L. Humboldtii*, var. *magnificum*, is nearest the northern form. This superb Lily has a large bulb, which is usually broader and rounder than in the type, and which speedily turns purple on exposure to the air. At its best it is even sturdier in growth than the type. The foliage is similar, dark green and glossy; the stem is much darker. The flowers, while of the same form and borne in a similar deltoid panicle, are differently coloured. At the middle of the flower the ground-colour is a rich orange-red; the maroon spots are surrounded by a reddish circle. On the upper half the reddish circles become larger, until they merge into each other at points, making an irregular combination of dark maroon spots, red ocellations, and of dark reddish-orange ground in blotches. This form of *L. Humboldtii* is found in the San Bernardino Mountains which make the southern end of the Sierra Nevada, in the Coast Range, as far north as Santa Barbara, in the Jacinto Mountains, and on some of the islands off the coast of southern California. There are some variations within this

range, but I am satisfied that bulbs from all of these localities grown side by side would prove practically identical. From the cultivator's standpoint it is important to observe, that while the *L. Humboldtii* of the northern Sierra seldom, if ever, flowers the first year, an ordinary bulb of the variety *magnificum* will bloom well the year it is planted, while even small bulbs of *L. Bloomerianum* almost always do. My information is, that the variety *magnificum* usually grows in the deep debris near the streams in shaded mountain cañons.

Lilium Bloomerianum is to the variety *magnificum* as a pigmy to a giant. Two or three feet usually measures its slender pale stem, and it is sparsely flowered. The much smaller flowers have a paler orange ground, and are not so richly coloured. The ocellations and red-blotched apex of segments are the same. The bulbs are small, not averaging one-fourth the size of those of the other forms. I have referred before to the peculiar two or three-jointed scales. I have seen bulbs in which nearly all of the upper joints readily rubbed off, leaving a mere stub of a bulb. *L. Bloomerianum* is found in the Pine belt of the high mountains of San Diego County.

The following figures, showing the average size of flowering bulbs of the forms of *Lilium Humboldtii*, may be of interest to some: In 750 bulbs of the typical *L. Humboldtii* 196 were from 9 to 12 inches in circumference, 351 from 8 to 9 inches in circumference, and 203 from 7 to 8 inches. The latter averaged 33 ounces in weight; second size, 43 ounces, and largest size, 9 ounces, with a few 14 ounces in weight. Bulbs of *L. Humboldtii*, var. *magnificum*, measure about the same, excepting that a few exceed these measurements.

Large bulbs of *Lilium Bloomerianum* will measure 6 inches in circumference, and weigh 23 ounces. Very many flowering bulbs measure 3 to 4 inches, and weigh 1 ounce each. *Curt Parry*, in "*Garden and Forest*."

CULTIVATION OF COLEUS.

A RECENT article published on this subject suggested to me a different way of growing these plants than that therein mentioned. Cuttings are made from robust specimens of the Coleus which it is desirous to propagate, and which have the brightest and most highly-coloured foliage. These cuttings are placed in frames, and in a fortnight or three weeks have rooted sufficiently to be transplanted into 60-sized pots. Cuttings should be made only in the beginning of warmer weather, when the sun's rays are increasing in power. This heat is an important factor with plants grown for exhibition. Shade should never be given. At the end of May the soil used for growing (it may be *Alternanthera*, *Tonatos*, or some other plants) is made up into beds in which the pots of Coleus may be plunged in frames. The plants should be in pots of suitable size, filled with rich and nourishing compost, and should remain in the frame all the summer. Air is excluded at night, and admitted in the daytime, according to the outside temperature.

The frames face south, and the plants are fully exposed to the direct and beneficial action of the sun's rays. In the height of summer the temperature of these frames often rises to 40° C. (104° F.). The whole secret of this method of cultivation consists in frequently syringing the foliage in sunny weather—that is to say, never giving water when the sky is overcast, but providing it in abundance when the sun is fiercest. By repeated pinching, nice bushy plants are formed, whose leaves are variously and brightly coloured, and well reward the grower. An experienced gardener told me, some years ago, when looking at a group of Coleus *Verschaffeltii*, "My father, who was a gardener in Belgium, had always in his 'pare Anglais' a much-admired bed of Coleus, shaded from the north, and exposed to the sun. The plants were never put out until June 2 or 3, and all came from strong cuttings made the same year. The bed, much raised, was well drained, and consisted almost entirely of horse-dung. When planting was over, the surface of the ground was covered 2 inches deep with farmyard litter. In the centre of the bed was a pipe, whence, on turning a tap, a fine jet of water played all

over the leaves and soil during the hottest hours of the day only. In the greatest heats of July and August the spray was only discontinued at sunset." In this kind of watering it is essential to discontinue it in time for the foliage to dry before sundown, except during the warm nights of July and August. As the plants grow rapidly, they need frequent pinching, which ensures a rounded shape. The centro plants will grow to over 5 feet in height.

This method of cultivation is practised in Belgium, where the air is generally dryer than in England, and the variations in temperature are less frequent. During the past hot summer what results might not have been thus obtained in England! This method of growing Coleus is by no means an imitation of their natural conditions. It is rare for these plants to flourish in the full sun, but there may be two reasons for the gardener's plan. A rule may be followed literally or intelligently; obeyed in the letter or in the spirit. But I should soon be led off into a dissertation upon plants with variegated and marked leaves. These colourations are, indeed, a degeneration, showing an unhealthy tendency. To intensify this complaint, this variegation, the exciting cause must be encouraged. Two distinct conditions must be considered; plants naturally variegated must be distinguished from those upon which the variegation is a "sport," or departure from a natural rule. It is the part of art to maintain and accentuate variegation; if natural, by stimulating and strengthening the plants by rich composts, fertilisers, and by admitting plenty of light. Plants with forced variegation require re-potting at long intervals, and always in a soil poor in nutritive qualities. In the former class are Caladiums, Coleus, Aphelandra, Dracaena (with some exceptions); in the second Cyperus alternifolius variegatus, Coffea arabica variegata, and, finally, all plants in which branches which are "sports" show the same characteristics when grafted or otherwise multiplied. *Louis Gentil.*

COLONIAL NOTES.

DOUBLE PSEUDO-BULB OF GONGORA MACULATA.

The illustration (fig. 50) shows a curious variation in a plant of *Gongora maculata* of the typical form, yellow in colour and fragrant, showing a new pseudo-bulb growing on the upper part of an old one, and the flower-spike issuing from the apex instead of from the base of the new growth. This plant belongs to a gentleman connected with the sugar industry. I have in my collection a pure white *Gongora*, which I believe is an albino of *G. maculata*. It is not the straw-white type, which has been described as indigenous to this island, but a pure white flower with a greenish tint in the mesochil, and altogether a very desirable variety of *Gongora*. *Thomas J. Potter, Trinidad.*

CENTROSEMA PLUMIERI, *Benth.* (THE SNAKE FLOWER.)

The boys about the district of the Botanic Garden, Grenada, call this climber the "Snake Flower," from a whistling noise made through the staminal tube after the style is pulled out and blown into by placing the tube in the mouth, and this is supposed to imitate the "whistle" of a snake. The standard, large and erect, is 2 inches wide, and nearly as long, giving in outline all but a perfect circle. Externally it is clothed with soft down. Inside there is a broad belt of a pinkish-purple hue, nearly divided in two halves by two yellowish streaks; the rest of the standard is of a whitish colour. The upper portions of the keel and wings are of a lighter shade of purple, with the remaining parts white. Upon the outside of the keel and wings are a number of very small hooks, which, when touched, cling to the hand and impart a sticky feeling. The leaves are made up of three leaflets, and, like the flowers, are borne upon short stalks. The plant prefers shady places, especially along banks, where the flowers oftentimes lie expanded upon the ground, but yet attached to the twining stems. The pea-shaped flowers are odoriferous, attractive, and well suited for horticultural attention. It is a common Grenadan plant, in the lowland districts. Seeds are freely produced.

ferous, attractive, and well suited for horticultural attention. It is a common Grenadan plant, in the lowland districts. Seeds are freely produced.

CENTROSEMA PUDICENS, *Benth.*

This *Centrosema* flowers much more freely than *C. Plumieri*, and differs in other respects also, as for instance, it inhabits more exposed places, and does well growing in the full blaze of the tropical sun, and ascends higher in climbing than does *C. Plumieri*. It is very common in the lowlands, growing alike upon fences and vegetation; in fact, it is a pest in some parts of the Botanic Garden. The flowers are not so large as those of *C. Plumieri*, nor are they so distinctly marked. In colour they are either creamy-white, and marked in the centre of the semi-globose standard with purplish lines, or sometimes are of a light purple with darker line-markings on either side of a broader whitish line in the central portion of the standard. Like the above-mentioned, there are numbers of minute hooked hairs, which also cling to the hand when the flowers are handled, and which cause a similar sticky sensation. *W. E. Brovday, Grenada.*

FIG. 50.—GONGORA MACULATA. Showing a new pseudo-bulb growing from the top of an old one.

TREES AND SHRUBS.

RHODODENDRONS IN EARLY MARCH.

UP to the time of writing, no season in recent years has been more favourable to the perfect development of early Rhododendrons out-of-doors than the present one. There are now at Kew some half-dozen species and varieties in full flower, which in beauty and showiness quite eclipse anything else among hardy trees and shrubs, and show how much can be done with these plants in favourable seasons. First among them in the brilliant effect it produces is *R. precox*, of which there are some three or four bushes near King William's Temple, from 2 to 3 feet high, and liberally covered with the lovely pale rose-purple flowers. This is of hybrid origin, and near it, and also in bloom, is one of its parents, the pretty Siberian *R. dauricum*, whose flowers are smaller, and of a deeper purple than *R. precox*. In the same group also is *R. Japhanoides* (a name, by the way, applied to two varieties); it has purple flowers, not unlike those of *R. dauricum*, but larger.

The remainder of the Rhododendrons in bloom belong to the Himalayan section, and are to be seen in The Dell, near the Bamboo Garden, where all the larger-growing species and varieties are cultivated. Owing to their numbers, the most noticeable are the old, well-known *Nobileanum* and *atacerense*, both hybrids owing to *R. arboreum* as one of the parents.

They are now furnished abundantly with fully or partially-opened trusses of rosy-scarlet blossom. These old hybrids have fallen somewhat into disrepute, owing to their flowers being so frequently cut off by frost; but if only once in five years we get a display like that of the present season (and with a carefully-selected position it will come much oftener than that), they are worth representation—in a small way, at any rate.

Perhaps the most striking, not only of Rhododendrons, but of all shrubs now in flower, is *R. fulgens*, which in its true form is very rare. This has compact rounded trusses, 3 or 4 inches across, of closely-packed flowers of the richest and brightest blood-red. Completing the tale comes *R. Thomsoni*, a species not far behind *R. fulgens* in depth of colour, but quite distinct. It has loose trusses of more or less drooping flowers, the latter larger than those of *R. fulgens*, and of a slightly paler shade.

STACHYRUS PRÆCOX.

This curious Japanese shrub is not only one of considerable interest botanically, but is also deserving of note as one of the earliest-flowering of hardy shrubs. At Kew there is a specimen now very prettily in bloom, that has been grown outside for many years past. Like several Japanese shrubs reputed tender, this withstood the winter of 1894-5 with less injury than many of our native shrubs. The species has, however, in previous years been killed. Its flowers are of a pretty greenish-white, 4-inch across and cup-shaped, and they are produced in racemes about 2 inches long, which hang at intervals of 1 inch in a straight row from last year's branches. This shrub has been figured in the *Botanical Magazine* (t. 6531), and is there shown with leaves as well as flowers, but the plate was prepared from a plant growing under glass. Out of doors there is as yet no sign of foliage, but its leaves, when developed, are 4 or 5 inches long, toothed, ovate-lanceolate, and taper to a long fine point. The fruits are borne in racemes like the flowers, each one about the size of a large pea, and covered with small warts. There are only two species of *Stachyurus* known, the other being *S. himalaicus*, a native of North India. *S. præcox* was first introduced from the mountains of Nagasaki, Japan, but has since been collected by Dr. Henry in Central China. The genus is an anomalous member of the *Camellia* family. *W. J. B.*

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

B. H. W. WARD, Rayleigh, Essex.

Disbudding Wall-trees.—This is an important operation, and one which should not be entrusted to inexperienced men. The disbudding ought to have a definite idea of the results of disbudding, and bear in mind the size and the shape of the tree, endeavouring to form a fruitful tree in a few years; and should also bear in mind that by the suppression of superfluous shoots and retention of the fittest, a maiden tree may, if the pruning knife had not been previously applied to its shoots, be converted into a good-sized tree during the first year and that much can be done to change unshapely and ill-furnished trees into fairly symmetrical specimens by an admit manipulation and distribution of the young growths, although it may require two or three years to achieve the result. The disbudding of a tree should be performed at short intervals of time, so as to avoid checking growth to a dangerous extent. In thinning the young shoots which push from the base of shoots made the previous year, the lateral shoots should be selected at short intervals on either side the entire length of these shoots, the number of these laterals being determined at a later disbudding by the amount of wall-space available. In the case of maiden trees, almost every lateral growth should be employed in laying the foundation of the trees, rubbing out all foreign or fruit buds as they appear. The foregoing remarks, and especially meant to refer to Peach and Nectarine and other wall-trees, but are, nevertheless, applicable to other fruit trees which make much superfluous growth. The first trees to require attention in the direction indicated are the Alexander, Waterloo, Ambsen Juno, and Hales' Early Peaches, Early Rivers, and Lord Napier Nectarines.

Frost-servants.—When the blossoms open, it is a matter of great importance to shield the blinds quite secure for short periods, becoming windy, much damage may be done to the trees by the flapping of the blinds, destroying the young shoots and buds on the lower branches. I have known instances of this undesirable state of things happening, not through the blinds having been blown from the fastenings during the night, but owing to the upright poles being let into the ground too close to the wall, and too wide apart. In these circumstances, two lines of long beam-sticks should be tied across the uprights to prevent mischief being done in this way.

Miscellaneous.—Prunings of all kinds should be raked up and burnt. Scrapers should be fixed at certain points of the fruit pots and walls leading on to the gravel walks. Pieces of hoop-iron about 12 inches long let into oak stumps about 2 inches square, and from 15 to 24 inches long, according to the nature of the soil, make excellent scrapers.

THE KITCHEN GARDEN.

By W. Pore, Gardener, Highclere Castle, Newbury.

The Leek.—A sowing of Leek seed, to furnish the main crop of these plants, should be got in with as little delay as possible, sowing it in drills in the manner directed for Onions, or broadcast, as the plants need to be transplanted when sufficiently large. The Musselburgh variety is good for general use, but Sutton's Prieztaker or Dobbie's International are better for exhibition. Any part of last year's crop now in the ground may be lifted, and laid in on a shady border, so as to check the natural tendency of the plant after this date to run to seed. The ground thus cleared may be prepared for some other crop. Leeks sown under glass should be kept steadily growing in a temperature not exceeding 50° at night and 60° by day, with as much air as possible. Presently these plants may come into the cold pit or frame, and hardened gradually in readiness for planting out towards the middle of next month. Leeks should be grown in trenches prepared as for Celery, four or five rows being put in a trench, which may be got in readiness when opportunity offers. The trenches should be dug out to a depth of eighteen inches, and as wide as may be desired, and plenty of well-rotted, rich manure placed in the bottom and made firm afterwards, turning on the top of it nearly to the throw-out soil. On planting, let the roots go down as far as the manure, not pressing the soil hard round the plants; but leave the holes open till growth has somewhat advanced, when, by the repeated stirring of the surface with the hoe, the holes will gradually get filled.

Tomatos.—To provide plants for putting out of doors, early in the month of May some seeds may be sown thinly in shallow flats placed in a forcing-house or stove with a minimum degree of warmth of 65°, and when germination has taken place, standing the pots in full sunlight and close to the glass. When the seedlings have a few true leaves, and before they become crowded in the seed pots, pot them singly in 60's, still keeping them well up to the light. Do not let Tomatos get pot-bound before planting, but repeat them once or twice, and gradually harden off till they can be trusted in a cold frame, and afterwards in a sheltered position out of doors before planting them out.

Potatos.—The first planting of early varieties of Potatos should now be made in a warm border. The Ashleaf and the sets are the favourites for early cropping, and if round ones are desired, Sutton's A1 is excellent. Plant, if possible, where some kind of protection can be afforded from frost, as the crop is not out of danger till before the middle of May. The sets should be planted about 6 inches deep, 20 inches from row to row, and 12 to 15 inches from plant to plant in the rows. On heavy cold soils a liberal allowance of leaf-soil should be worked into the staple or laid in the furrows with the sets; and on light soils a dressing of Bones or other approved bone-manure may be sprinkled along the furrows when ploughed, and again before the sets are earthed up. Except in very mild parts of the country, it is yet too early to plant Potatos in quantity, but much may be done now to ensure success by laying out the sets thinly as I advised some weeks ago, the sprouts will then get sturdy and not be easily broken off if carefully handled. Potatos growing in pits and frames should be aired freely at all times when the weather is mild, not letting, however, cold air reach the tops, and always tilting the lights on the side from which the wind is not blowing. On bright mild days, the lights may be drawn off the frames for a few hours in the middle of the day. Coverings of mats and litter must still be made use of at night in more or less, according to needs.

THE FLOWER GARDEN.

By CHARLES HERRIN, Gardener, Drogheda, Maidenhead.

The Planting of a Herbaceous Border.—Assuming that a new border is to be made, and that the soil has been liberally dressed with well decayed manure, and trenched some weeks ago, planting may begin when the state of the soil becomes workable. The border, if consisting of light soil, or it has been only recently trenched, should be made firm by trampling it evenly and regularly all over, and afterwards be levelled. No border of perennial plants looks well if the plants are arranged in straight lines and formal designs; rather should the various species and varieties be placed in small groups together, there being one or several such groups, according as the border is small or wide and long. Of course, the tallest plants should to a certain extent be placed in the middle of the border if it have two faces, or at the back if it have but one, dwarfier plants coming towards the front in each case; but this should not be too strictly adhered to, some of the plants of moderate height being grouped with dwarfier ones, so as to afford an undulating outline and do away with undue regularity. The perennial Sunflowers form extremely useful plants, that are in flower from June to late in the autumn. All of them possess flowers of a yellow hue as regards the rays, and central disc of brown, orange, or black. Most of them are tall in growth, and some, owing to their growing by underground stolons, are apt to become somewhat of a nuisance. *Helianthus multiflorus*, 5 to 6 feet; *H. m. flore plenus*, 5 feet; *H. decapetalus*, 5 feet; *H. occidentalis*, 4 feet; *H. rigidus*, 3 to 4 feet; *H. laetiflorus*, 4 feet; and *H. orgyalis*, a tall, late-flowering species with handsome Willow-like foliage, are all of them desirable Sunflowers. *Spiraea* forms a handsome class. *S. aruncus* is a noble subject when in bloom, and should not be omitted; it grows from 4 to 5 feet in stature. *S. astilboides*, a distinct and beautiful plant, 2 feet high; *S. japonica*, a dwarfier species, is a well-known plant; *S. filipendula* flower-plano and *S. venusta*, with pretty rose-coloured flowers, are worthy of a place in any garden. *Anchusa italica*, a Boraginaceae plant, with flowers borne on strong spikes 4 to 5 feet in height, is an acquisition, no other subject equalling it in the intensity of the blue colour of its flowers; it flowers from June to September. Other tall-growing plants are *Delphiniums*, double and single, in variety; *Phlox decussata* hybrids, early and late-flowering; *Solihago virga aurea*, *S. altissima*, and *S. multi radiata*; *Boconia cordata*, a strong-growing plant with corolla foliage and spikes of coral-coloured flowers, striking and handsome; *Verhascarius*, including the pretty *V. Chasii*, growing 5 to 6 feet high. Herbaceous Peonies planted in groups of three to five have a fine effect, and should be freely planted in both double and single-flowered varieties. *Baptisia australis* and *B. exaltata*, old-fashioned border plants, with blue pea-shaped flowers, the foliage, which is useful for arranging with various cut flowers; the plants in height from 2 to 4 feet. *Helenium autumnale* and *H. a. grandiflorum*, *Galega officinalis* and *G. o. alba*, *Dictamnus Fraxinella* and *D. f. alba*, *Hesperis matronalis* fl.-pl., the old double white Rocket, so sweetly scented and useful for Helenium; *Eryngium amethystinum*, *Rudbeckia speciosa*, and *R. purpurea*; *Campanulas* in variety, *C. persicifolia* and *p. alba*, being two which should not be omitted. *Gypsophila paniculata*, *Tritomas*, *Asphodelus luteus* and *albus*, the early-flowering *Thalictrum aquilegifolium roseum*, *lula glandulosa*, *Menorcallis flava*, *H. kwano*, and the double-flowered variety. Early-flowering *Chrysanthemums*, *Doronicum plantaginifolium excelsum*, *Monarda didyma*, *Echinops Ritiro* and *E. rubicentus*, *Lycinis chalcidica* and *Clenatis erecta*. Plants for the front portion, growing from 6 inches to 2 feet in height, should include *Picotees*, *Pinks*, and *Campanulas* in variety, *Ornitho verus*, *Helenium minimum*, *Heuchera sanguinea*, *Dianella coriifolia*, *Pyrethrum* in variety, *Phygelius capensis*, *Napaver medicinale* in variety, and *P. orientale*; *Anemones apennina* and *japonica*, *Funkias*, *Iris* in great variety, *Geranium*, English, and Spanish; *Achilleas* *ptarmica*, fl.-pl., and *The Pearl*; *Armerias*, *Aubrietias*, and *Gentians*, may be used for forming edgings to the borders. Bulbous subjects, as *Liliums* of various heights and colours may be dotted about in small groups, and *Montbretias*, *Astroceras*, and other groups. *Crocuses*, *Scillas*, *Daffodils*, and other low-growing bulbous subjects may be planted at a good distance from the edge of the border, and after the foliage has died down, any bare spaces may be sown with annuals. The *Michaelmas Daisies* form a large class, and add to the autumn beauty of the garden. The following are a dozen good varieties.—Harpur

Crewe, and *Purity*, white-flowered, 4 to 5 feet; *Robert Parker*, lavender-blue, 5 feet; *Nancy*, pale blue, 4 feet; *Anellus-bessarabicus*, 2 feet; *Levi-gate*, rose-coloured, 2½ feet; *acris*, 2 feet; *cordifolius Diana*, 4 feet; *ericoides*, 3 feet; *Maia*, *Trasycyllac*, 4 feet; *diffusus horizontalis*, 3 feet; *Redesantii*, late-flowering, small white, 4 feet.

Seeds to be Sown.—*Ricinus*, *Cannabis gigantea*, *Melanthus major*, *Nicotiana*, *Variegated Maize*, and *Solanum robustum*, for subtropical bedding. The *Ricinus* seeds should be sown simply in small pots, being bad subjects to transplant from seed-pans, any breakage of the young roots often causing the death of the seedlings, and when sown in single pots they rot better, or without check. *Verbena*, *Petunias*, *Penstemon*, *Antirrhinum*, and *Lobelia speciosa* are other seeds that should also be sown if strong plants are desired by bedding-out time. Use pots or boxes filled with light soil, scattering the seeds thinly, and covering them more or less according to the size of the seeds; keep all seeds well shaded till germination takes place.

PLANTS UNDER GLASS.

By G. H. MARCOCK, Gardener, Luton Ho, Luton.

Tuberous-rooted Begonias.—As soon as time permits most or all of the tubers should be potted. My practice is to winter these in shallow boxes, with just sufficient soil over them to prevent shrivelling taking place; and I select those for the first potting that are beginning to grow, leaving the others to be potted later, and thus lengthen the season during which the plants will flower. After potting, place the tubers near the glass in a form, in which they have a genial temperature. Seedlings of this type of *Begonia* may now be pricked out in shallow, well-drained, earthenware pans or wooden boxes as soon as it is possible to handle them, using a pronged stick to lift them out of the soil, and a tiny dibber for setting them. These young plants should be kept near the roof-glass in a house or pit, and well shaded when the sun shines.

Violas.—Plants in frames should be copiously watered in the early morning when it is found that the soil is getting dry, choosing a bright day for doing the work. Do not leave decaying matter about the plants, or omit to ventilate freely, whenever there is no frost, even keeping the glass at night in this manner. At this season efforts should be directed to maintaining a healthy stock of plants from which to propagate next month. Red spider give little trouble if the soil of the beds is kept in a moist condition, and the plants are occasionally syringed, especially the lower sides of the leaves, with a nozzle-syringe in the forenoon of warm days, and afterwards leaving off the frame-lights, so as to dissipate the over-abundant moisture before nightfall. If, despite these precautions, it should begin to spread over the plants, the XL All vapour should be employed against it.

General Hints.—Harrison's and the common Musk should be struck from cuttings or pieces of the roots, using for this purpose small 48's, and a mixture of sandy loam and leaf-soil, in equal proportions. *Selaginella denticulata* should be similarly dealt with, but putting, however, a handful of decayed dung below the soil, and affording plenty of drainage. The seed-vessels of plants of *Azalea indica* which have been forced should be removed without delay, and those plants of *Azalea* in need of re-potting, should be attended to after flowering is past, and growth has begun. The Indian *Azalea* likes as a rooting medium hard fibrous peat, half-decayed, in a stack, and plants of clean sharp sand mixed with it, the more if it be naturally deficient in sand; and broken sandstone may be also used for large plants. As drainage, it is better to use a few large crocks at the bottom of the pot, and above these a layer of finely-broken crocks, and over the latter nodules of peat of about the size of acorns. Loosen the roots at the sides of the ball, and if these are much matted together, shave off a thin slice all round; take out the old crocks if not much embedded, and let the ball be one-half to an inch, according to size of plant, lower than before. Fill in with small quantities of the soil, making it firm with a potting-stick, each time before putting more soil into the pot. The potted, and the unpotted plants from which no bloom is expected, should be placed in a house having a night temperature of 60°, and a day temperature of 75°, closing it between 2 and 3 P.M., and generally keeping it moist, and the plants syringed in the morning at 7 A.M., and at closing-time. Allow the plants ample space, turning them round once a week; do not use any manure-water to plants that have been recently re-potted.

and only very weak guano-water once in eighteen days to those which have not been re-potted. It may here be said that Azaleas in an untrained or but little trained form are more handsome than those stiff, ungainly pyramids and balloons once so common; and if some of the branches grow downwards, and partially downwards, the better is the effect. It is hide the pots, so much the better is the effect. It is sometimes necessary to cut Azaleas hard in; this however is best done in late autumn (and it should not be too severely done), as then the old wood will bristle with shoots when the plants are placed in heat at this season. The temperature should be a few degrees higher than that afforded the other part of the stock of these plants, and the house kept closer till a good break is obtained. It is at this season that grafting may be done, if desired, using as a stock A. of the purple or other strong-growing varieties. Cut-back old plants may also be grafted with desired varieties, keeping them also in a warm greenhouse. Prepare pots and pans for the seed-sowing of both stove and greenhouse annuals, and lose no time in getting the bulk of them sown. Afford weak dressings of artificial-manure to Carnations generally, and stake early those plants requiring support, fumigating them occasionally.

THE ORCHID HOUSES.

By W. H. WATTS, Orchid Grower, Burford, Dorset.

Calanthes.—The deciduous *Calanthes* will soon be in a condition to be re-potted, and a sufficient quantity of good fibrous loam should now be selected and laid in some convenient place, where it may become moderately warm before it is made use of. Loam is the principal soil needed by *Calanthes*, and coar-dung forms an excellent ingredient to mix with it. The latter should be prepared by exposure to the sun until it is quite dry, and afterwards rubbed through a fine meshed sieve, and turned over occasionally until needed for use. The position in which the plants will be placed after the re-potting should be made perfectly clean; the woodwork, rafters, &c., and the glass both inside and out, so that the plants may have a good clear light during their season of growth.

East Indian-house.—Such plants as *Renanaetha coccinea*, *R. Storei*, *R. Warocqueana*, *Vanda Hookeriana*, *V. Miss Joachim*, *Vanilla aromatica*, *V. planifolia*, *V. Walkeriana*, and *V. Humboldtii*, having commenced to grow should be placed together at one end of the house, where they will obtain much sunlight. These species require their aerial roots to be moistened with a fine syringe several times a day. *Vanda teres*, given the same treatment, will grow and flower freely in the lower temperature of the Mexico-house. *Vandas* of the *suavis* and *tricolor* section should now be given more water at the root; their flower-spikes being just discernible. Do not syringe them overhead, or the water will accumulate in the axils of the leaves, and cause decay. These handsome, tall-growing plants must be protected from strong sun-shine, or they will lose their lower-most leaves.

Mexican Division.—Plants of *Odontoglossum citreum* are beginning to grow. No water need be afforded the plants before the growths are well advanced, but immediately the flower-spikes are seen afford them a thorough soaking at the root, and afterwards place them in a warm, moist atmosphere. Woodlice and slugs must be prevented from injuring the young spikes. It is also a good practice to place beetle-poison on the plants to destroy cockroaches.

Cymbidians.—Any plants of *C. eburneum*, *C. alpinum*, and *C. Mastersii*, that have just done blooming, or those of *C. Lowianum* that are producing young growths instead of flower-spikes, should be re-potted at this season if they need it. Also such species as *C. Theophrasti*, *C. Hookerianum*, *C. cristifolium*, *C. longifolium*, *C. chloranthum*, *C. elegans*, *C. giganteum*, and *C. sinense*. *Cymbidians*, as a rule, do not take kindly to root disturbance, and it is not expedient to re-pot them unless there is good reason for it. When this is necessary, give the plants a good shift, that will suffice for several years. Give good drainage, and instead of elevating the plant above the rim of the pot, keep the soil at least half an inch below it. The compost should consist of one half good turfy loam, the other half peat and leaf-soil, which may be added some small crocks and a little coarse silver sand. *Cymbidians*, when in full growth, require plenty of moisture at the root and in the atmosphere. They should be grown in the coolest and most shady position in the intermediate-house during the whole year. Plants of *C. Lowianum* and its distinct variety *viride* (one-color), also the beautiful hybrids *C. eburneum-Lowianum*, and the reverse cross *C. Lowianum-eburneum*, that are in bloom, should not

be disturbed until the spikes are out. *C. Devonianum*, which is now in bloom, is suited for basket culture. The pretty dwarf-growing *C. bigyana* from Tennessee, at 6,000 feet elevation, should be given the warmest part of the *Odontoglossum*-house.

Cypripediums.—Plants of *C. Leeanum* × *C. isagine*, *C. Charlesworthii*, *C. villosum*, *C. Boxallii*, *C. venustum*, *C. porporatum*, *C. Sallierii-Hyeanum* × *C. Schlimi*, *C. Amesianum* × *C. Williamsianum* × *C. radiosum* × *C. Arthurianum* × *C. Niobe* × *C. Statterianum* × &c., which may have become pot-bound, should now be re-potted. Afford liberal root-room, with plenty of drainage, and pot firmly with lumpy fibrous peat and a little sphagnum-moss. As all of these plants require abundance of water during their growing season, it is good practice to make the compost absolutely porous by mixing pieces of crock, turf, or broken brick with it. These plants must be well shaded from strong sunlight at all times. A cool damp position in the intermediate-house is the best place for the above-mentioned species and hybrids at all seasons. At the present time the rare *C. isagine Sandere* and *C. i. Ernesti* appear to grow better if placed in a little more warmth than is recommended for the species. *C. superbum* (Veitchii) may be re-potted if necessary. It should be grown in the warmest part of the *Cypripedium*-house, care being taken not to expose it to the least ray of sunshine, or its beautiful mottled leaves will lose their freshness and colour.

FRUITS UNDER GLASS.

By F. HARRIS, Gardener, Eastnor Castle, Leicestershire.

The Early Vinery.—If the Vines in this house were started on or about December 1, they will now be coming into flower, in which stage a little more warmth, viz. 65° at night and 70°–75° by day, is required, or is beneficial; and the air should be kept somewhat dry, in order that the pollen may get better distributed. If the varieties are Black Hamburgh and the Seedling, a gentle tapping of the roots at about noon daily will suffice to obtain a good set; but if *Muscats* are shortly expected to be in flower, it is a good practice to hold a shallow box under the bunches as they are tapped to catch the pollen as it falls, which, if kept perfectly dry, will be found to greatly assist *Muscats* to set freely if applied with a camel-hair pencil carefully drawn over the flowers. If plants are cultivated in the early house, they ought to be cleared out while the Vines are in flower, otherwise the set will probably be interfered with. If the hot-water pipes are furnished with evaporating-pans, the latter should be emptied for a few days, a slight damping of the paths and borders at closing time affording enough moisture. As soon as the flowers are all set, a good application of tepid water to the border inside will do much good; and the usual damping-down may be resumed, doing this twice or thrice daily, a canful of manure-water being used for damping-down the last thing. When it can be seen which are the best bunches, reduce the number on a Vine to what it is believed it will bring to perfection without being unduly exhausted. There should have been a still earlier thinning of the number of the bunches, all those which it is apparent cannot make nice bunches being taken; this in most cases will benefit the Vines. At the second removal of the bunches they should be left evenly distributed over the whole of the Vines, not thickly here and sparsely there, as is sometimes observed; taking care to leave those which hang the more conveniently for thinning, for if a good bunch be left in an awkward position, it is unavoidably spoilt somewhat by the operator rubbing or pricking the fruits. In thinning a bunch, the first thing to be sure of is that the shoot on which the growth is firmly tied to the trellis, or after the shoulders have been secured by ties, the weight of the growing bunch will bring the shoot lower, and render the tying useless or injurious. Tie the shoulders up as much as may be required before commencing to thin, or berries will be removed which should be retained. First cut out all the seedless berries, then thin the others to the required distance, remembering that early Grapes should not be as much thinned as the late ones. Use a short-forked stick to steady the bunch, and never allow the fingers to touch the berries. Start at the bottom of a bunch, and finish at the shoulder, leaving as many berries as possible in an upright position at the top, which will then close up compactly, and no stalk will be visible. The lateral shoots must be kept in check, so as not to crowd the trellis with growth and leaves, but encourage as much as possible those leaves behind and just in front of the bunches; and wherever practicable, allow a

shoot to run at the back of the vine or elsewhere, as by doing this the Vines are considerably helped at this part of their career.

Succession Vines.—The Vines in these vineries will now require their shoots to be tied in, their points stopped, &c. In tying these shoots, keep the points clear of the glass, and especially if the Vines are young ones, as if this operation be hastily performed, some of them are sure to be broken out, than which nothing is more annoying. Stop every shoot at the second joint beyond a bunch, or reserve the same number of joints if there be no bunches on the shoots. Do not be over-anxious to get the shoots quite down to the trellis all at once, as at this stage they are very brittle, whereas after flowering the wood is not so liable to snap.

Young Vines which, having been bent low down, are about to break into bud, should be secured in their places before the buds are far advanced. Should such Vines have broken irregularly, rub off one or two of the terminal breaks, which will probably have the effect of causing the backward buds to push. Any Vines which have not as yet broken should be well syringed two or three times a day.

Grape-room.—Where Grapes are still in the Grape-room, look them over frequently for bad berries, and see that the bottles in which they are placed are filled with water.

THE APIARY.

By EXETER.

Stock Short of Food.—The recent sunshine is bringing out the bees from every hive, and in most cases they are coming out in strong condition; but the very open weather we have had this winter has sadly reduced the stores in the hives, and the bees are dying from sheer want. This is most annoying, as it frequently involves the chilling of the brood. In a severe case it is best to remove the hive bodily indoors in the dusk of the evening, and place it in a warm room; take out a comb next the benumbed bees, and substitute a frame of comb the cells of which are well charged with warm syrup; then close the hive entrance, replace the quilts, and set above them several heated bricks. Very soon the bees will be found to be moving about, and when strong enough, the hive should be removed to its usual place. All dead and chilled brood must be taken from the hive; and it must be understood that in desperate cases of this sort, warm syrup must only be given, candy being in use whatever. When stores are short give them soft candy, as it is much too early to feed them with syrup, better wait till the month is out.

Old Combs.—It is useless to expect that all hives will come through the winter well, and bees doing well; a word then about old combs will not be out of place. As soon as you find a stock is dead, close up the entrance to keep robber-bees away, and then, at the first opportunity, examine all the combs, and if they are dirty and old, place them in the melting-pot. If very bad, and there is the slightest suspicion of foul brood, burn them at once, rather than use them again, and contaminate the whole apiary; if, on the other hand, no cells of unhatched brood are found in stocks where the bees have perished, the combs may be used again with safety, and very useful they are to place swarms on to. By carrying out these few directions all risks are reduced to a minimum.

Uniting in the Spring.—When examining hives if one lot is found to be very weak, and has a poor queen, do not hesitate to join it to the next, it will repay you in honey and swarms, whichever you require; but if you waste time in trying to feed up the weak stock, you will find all your time has been thrown away, and there are no good results.

Quilts.—Many who believe in non-porous quilts for the breeding season, must soon commence to suit their fancy. Some like porous, others non-porous, and again, some like carpets. For my part, I have tried them all, and with young prolific queens and spring feedings, they all seem to be found to come out well and ready for the honey season. Floor-boards should all be scraped clean of small pieces of wax, &c. This will save the bees a good deal of time and labour. A small piece of iron, bent at one end, is a very good tool to use for it. Where door-boards are not nailed down, an old knife will quickly do the work.

Plants for Bees.—Now is the time to plant all sorts of flowers for bees, such as Nasturtiums, Sunflowers, Clover, Borage, and a host of others suitable for them.

Orders.—Do not put off getting in what is required, but order at once, as oftentimes the dealers sell out their best stock first, and if your orders are delayed, when your goods arrive you will be disappointed.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of this paper, and us early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but retains a guarantee of good faith. The Editor does not undertake to pay for contributions, or to return unacknowledged communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early and full notices likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction in these pages, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TURSDAY, MAR. 10.—Royal Botanic Society Meeting.
WEDNESDAY, MAR. 11.—Devon and Exeter Gardeners' Society's Spring Show.

THURSDAY, MAR. 12.—Lincoln Society Meeting.
Spring Show at Ebleydon Estate Gardens, Tewkesbury.

SALES.

GREENHOUSE PLANTS and Ferns, Herbaceous Plants, and Hardy Border Plants in variety, at Protheroe & Morris' Rooms.

TUESDAY, MAR. 10.—Cannas, Begonias, Carnations, Aspleniums, &c., at Protheroe & Morris' Rooms.

WEDNESDAY, MAR. 11.—276 Cases of Japanese Lilies, Azaleas, Bosses, Fuchsias, Ornamental Plants, &c., at Protheroe & Morris' Rooms.
Sale of Plants, Orchids, Greenhouses, &c., at the Burlington Down Nurseries, Clifton, Bristol, by order of Messrs. Taylor & Co., by Protheroe & Morris (two days).

GREENHOUSE PLANTS, Plants, Shrubs, &c., at Stevens' Rooms.
Hardy Perennials, Fuchsias, Iris, Bosses, &c.; also 1000 Cattleya Mossii and other orchids, at Protheroe & Morris' Rooms.
Special Sale of Border Plants and Bulbs, at Stevens' Rooms.

THURSDAY, MAR. 12.—Establishment Imported Orchids at Protheroe & Morris' Rooms.

FRIDAY, MAR. 13.—Establishment Imported Orchids at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chilwick.—42.77.

ACTUAL TEMPERATURES:—LONDON.—March 10: Max., 52°; Min., 41°
PROVINCIAL.—March 10 (6 P.M.): Max., 47°; Scilly; Min., 39°; Malta Head.

Crested Cyclamen.
The genesis and maintenance of variations are matters which astonish the laity, and confound the experts. How, for instance, can we account for the production of crested Cyclamens, which first came under our notice in 1885? (See *Gardeners' Chronicle*, April 25, p. 536, for figure, &c.) The productions in question are enations or out-growths from the petals, such as we have often met with in Chinese Primroses, in double Daffodils, Glorinis, and other plants, and which are, in fact, homologous with similar out-growths from the leaves of the Kuls. In many of these cases, the relative position, or, as botanists call it, the "orientation" of the elements of the fibrous cords or vascular bundles is reversed; thus, in an ordinary petal, the bast-cells (phloem) are below; the wood-cells (xylem) above, $\frac{a}{b}$, while in the enations the position of the two elements is reversed, $\frac{b}{a}$. If we look on the leaf or petal as representing one-half of an axis,

then, this new production may be taken to represent the other half thus: $\left. \begin{matrix} b \\ a \end{matrix} \right\}$; and, if we

further suppose the edges that are in general free and detached to be united, we then get a hollow cylinder or tube, instances of which are very common. So far, then, there is nothing absolutely new about these Cyclamens. In the first instance, we may infer that their production is due to hypertrophy, or over-growth, caused by excessive feeding; but that is only a guess, and does not help us to understand the spread and increased development of the peculiarity. Messrs. Low & Co., as we know, exhibited some specimens of this variety at a recent meeting of the Royal Horticultural Society, and have subsequently displayed it in Belgium and in France. And now we learn from the *Revue Horticole* that M. ETIENNE NARBOUTON, a gardener at Maisons-Laffitte (Seine-et-Oise), France, has had a similar 'cyclamen, but of a red colour, for the last three years, and that the characteristics are reproduced from seed. In this case, then, we have had a variation, as it were, formed beneath our eyes, and one, moreover, which in so far resembles a species that its characteristics are reproduced from seed.

If these crested Cyclamens should take the public taste, we may expect to see great developments in this direction; but if, as is quite as likely as not, they fail to attract attention, they will disappear and be no more seen until what we, in our ignorance, call accident once more brings them to light.

It is curious to note that all the now numerous forms of Cyclamen are derivatives from one species, *C. persicum*. In many of these cases the changes arise from hybridisation of two or, eventually, of several species, as in tuberous Begonias; but the Persian Cyclamen has, we believe, not been crossed with any other species, or, if it has been, the results are not known to us. The amount of variation of which an uncrossed species is capable is well illustrated by the Chinese Primrose, whose history was detailed in these pages when the wild plant from Yehang was first brought into cultivation in this country.

DAPHNE INDICA RUBRA AT BERKELEY CASTLE.—Daphnes of all species are plants of comparatively slow growth and moderate size under cultivation. The specimen of *D. indica rubra* which fig. 51 shows is the more remarkable, seeing that this plant and others in the same house measured 6 feet in height and breadth. These plants were struck from cuttings about sixteen years ago, and they are planted in a border. The plant succeeds in a mixture of two parts of unctuous loam, one of fibrous peat, and the same proportion of sharp sand. *D. i. rubra* differs in regard to its flowers from *D. i. alba* by the former having a red-coloured under-surface, and *D. i. rubra* is a better deer under pot culture than the latter variety, and is not so much subject to red-spider. The conditions under which Daphnes succeed under glass are similar to those found to suit the Camellia. We are indebted to the kindness of Mr. SOANE, the gardener at Berkeley Castle, for the photograph from which the illustration was taken.

KEW.—The furnishing of the Alpine house has just commenced, and among the plants which may now be seen there, are *Morinda hypogaea*, a small tinted crucifer, with a rosette of deep green, deeply pinnately divided leaves, from the centre of which arises a flower-stalk 2 to 4 inches high, with two to five bright yellow flowers. The plant is very striking in appearance, though, as yet, little known out of

botanic gardens. *Saxifraga apiculata* shows a mass of yellow flowers—this is the species originally called *luteo-purpurea*. *S. Bursleriana* is very beautiful in its profusion of white flowers, and *S. Boydii alba* is scarcely inferior; *Fritillaria citrina* is well represented, and *Stortia galicifolia* gives hope for the future. *Crocus Malyi*, *Noceca stylosa*, may also be noted in this house, which in another week probably will be replete with beauty and interest, as it generally is at this season. On the rockery, *Saxifraga sancta* (yellow), *Anemone* (*Hepatica*) *angulosa*, and the Pyrenean form of *Saxifraga oppositifolia* are very attractive. The *Heliolebas* are coming on in force, *Daphne Blagayana* is in full bloom, and things are coming on so rapidly that the plant-lover will soon experience the usual impression that time will not permit him to study the floral detail presented to him. The turf is speckled with blue from the thousands of *Chionodoxa* of various kinds. Snowdrops, which have been even more numerous, are now passed out of flower.

The furnishing of a conservatory or greenhouse often forms the subject of an enquiry in these columns. Whenever practicable, we recommend the enquirer to visit the show-house at Kew. The house No. 1 is kept gay throughout the year with ordinary plants, and very often the visitor may have in addition the good fortune to see plants which he could hardly see elsewhere. This display of rare or new plants is one for which the authorities cannot be too highly commended, and it is one that need in no way interfere with the requirements of the populace. The fine plants in pots of *Saxifraga Stracheyi*, for instance, form an excellent object-lesson for those who have to fill conservatories or window cases. Very showy and better known are the *Cinerarias*, Chinese *Primulas*, *Cyclamens*, *Hyanthids*, *Tulips*, *Azaleas*, *Cleomeas*, *Acacias*, *Narcissus*, *Eriostemonas*, *Begonia semperflorens*. The *Camellias* which were planted out, are over, but *Cestrum fasciculatum* is still in flower, and, indeed, it would require a catalogue of some length to include all that may be seen in the show-house.

THE KEW GUILD.—Owing to a printer's error, the invested fund of this guild was stated in our last issue to be £10. It should have read £100.

LINNEAN SOCIETY.—On the occasion of the evening meeting, to be held on Thursday, March 18, at 8 P.M., the following papers will be read:—1. "Further Observations on *Stipules*," by the Right Hon. Sir JOHN LUBBOCK, Bart., M.P., P.C., F.R.S., &c. 2. "On the Origin of transfusion-tissue in the leaves of *Gyanospermous Plants*," by Mr. W. C. WORSDELL.

THE MIDLAND CARNATION AND PICOTEE SOCIETY.—We have received the sixth annual report of this society, which includes a full list of awards, and a list of the subscribers and balance-sheet for 1896. The show held on Friday and Saturday, July 24 and 25, was considerable, from the exhibitors' point of view, a success, the competition in most of the classes being stronger than on any previous occasion. The society maintains its reputation, and new members have joined it in considerable numbers. The balance this year not being so large as usual, the support hitherto given each year to the Royal Gardeners' Benevolent Institution and to the Royal Gardeners' Orphan Fund is omitted, but the committee hope to continue their support in the future. The receipts for the year 1896, including balance from the previous year of £40 2s. 4d., amounted to £225 17s. 2d., and the expenditure to £188 12s. 9d., which leaves a balance to the credit of the society of £37 4s. 5d.

PRESENTATION.—The Duke and Duchess of PORTLAND have presented Mr. JORDAN, the head-gardener at Impney Hall, Droitwich, with a valuable silver tea-pot, bearing the following inscription:—"Presented to Mr. F. J. JORDAN by the Duke and Duchess of PORTLAND, on leaving Welbeck, September 18, 1896." The above is a much-prized and valuable addition to the numerous presents Mr. JORDAN received on leaving Welbeck to take charge of the gardens at Impney.

FIG. 51.—*DAPHNE INDICA RUBRA*, IN THE GARDENS AT BERKELEY CASTLE, GLOUCESTERSHIRE. (SEE P. 172.)

THE NATIONAL AURICULA AND PRIMULA SOCIETY.—We have before us the twentieth annual report of the Southern Section of this Society, from which is gathered the fact that the membership has received a further increase. A notable feature of the last show was the exhibit of the Rev. F. D. HORNER, consisting of twelve show varieties of Auriculas, ten being of his own raising, and two of Mr. BEN. SIMONITE'S, one only of the twelve, viz., Heatherbell, being in commerce. The premier Auricula, Mrs. Howwood, raised by the late S. BARLOW, is a remarkable green-edged flower, and a welcome addition to its class. The committee have, with much regret, to report the resignation of the honorary secretaryship by Mr. J. DOUGLAS, which he has held for upwards of twenty-one years. The annual exhibition of the Society will be held in The Drill Hall, James Street, Victoria Street, S.W., on April 13, under the auspices of, and at the same time as the meeting of the Royal Horticultural Society. The account of receipts and expenditure for the year 1896 shows—receipts, £52 7s.; expenditure, £71 14s. 6d.; and a balance in hand of £19 12s. 3d.

POTATOS.—At the last meeting of the Farmers' Club, Mr. ARTHUR SUTTON delivered a lecture comprising 1, the Botanical description; 2, the Introduction of the Potato into Europe; 3, Deterioration and Disease; 4, Disease Prevention—*a*, by spraying; *b*, by raising seedlings; 5, Species and Varieties; 6, Modern Introductions; 7, Cultivation and Reports of Experts. Under the latter head many agricultural and statistical details were given. The lecture was similar to those already reported at the Royal Horticultural Society and in Dublin, and was copiously illustrated with lantern-slides.

TRURO DAFFODIL SHOW.—The unusual forwardness of vegetation, due to the mild weather, is rendering necessary the alteration of the dates of spring flower shows. Mr. J. BOSCAWEN, Hon. Secretary of the Truro Society, desires us to state that the date of that bulb show is now fixed for March 16 and 17.

ROYAL BOTANIC SOCIETY.—At a meeting of this Society, held on Saturday, February 27, Mr. JOHN BIRKETT, F.L.S., in the chair, the Duke of BEDFORD, Sir G. HAMOND GREBE, Bt., and nineteen others, were elected Fellows. A paper was read by Mr. MARTINDALE, calling attention to the great desirability of establishing in London an institution for the purpose of teaching botany, similar to those in existence on the continent, and proposing that the Council should take charge of the scheme, and utilise a portion of their ground for the erection of the necessary buildings. From its central position, and the fact of all the requisite material for study being at hand in a living condition, no other site in or near London would be so suitable for the purpose. The great fault of the present system of botanical teaching in England outside the medical schools and universities was, that too much attention was given to botany, solely with the object of enabling students to pass examinations, while economic and physiological botany was scarcely touched upon. If a young German were desirous of emigrating, previous to doing so he could attend a short course at one of the institutions at home, and learn all that would be of most use to him about the grasses, fruits, and vegetable products of the country he proposed to settle in; but in England there is no such means of acquiring knowledge of this kind, and it was for the purpose of supplying such a deficiency that the establishment of the institute is proposed. Among those present who gave the scheme their hearty support, were Professor OLIVER, of University College; Mr. D. H. SCOTT, of Kew; Professor HENSLow, Professor GREENISEN, Mr. M. CALVEGHE, Mr. E. M. HOLMES of the Pharmaceutical Society, and many other eminent scientists.

THE NATIONAL CARNATION AND PICOTEÉ SOCIETY.—The committee of this Society, reviewing its position during the past year, report that it has more than maintained its hold in the estimation of

the public, in evidence of which is the fact of an accession of eighty new members during the year, raising the total to 300. The date of the show this year will not be fixed till a fairly trustworthy opinion can be formed as to the probable date of the maturity of the blooms; and the committee propose to hold a meeting in June, and as soon after such meeting, advise the members by circular, and the public by advertisement, of the date of the exhibition; which will be held at the Royal Botanic Gardens, Regent's Park. The committee lose with regret Mr. James Douglas, who for a period of twenty-one years has occupied the position of honorary secretary, during which he has rendered excellent and valuable service to the society. Mr. T. E. HUYWOOD has kindly consented for the present to act in the capacity of honorary secretary. The income of the Society for the past year amounted, together with a balance of £195 19s. 1½d. from the previous year, to the sum of £471 7s. 7d., and the expenditure to £233 6s. 4d., leaving a balance of about £238.

ISLE OF WIGHT.—A correspondent in the island remarks that the last month was the mildest experienced for the past ten years, the nights being particularly warm. As a consequence, vegetation is unusually forward, and blossoms of Primroses, Violets, Anemys, and Aubrietias are plentiful in gardens. Butterflies and moths could be seen on the wing, and the hum of bees was heard; but a severe check came with the first days of March, and a furious gale from the south by south-west occasioned much damage to plants, trees, and buildings all over the island.

TASMANIAN FRUIT SEASON.—The Managing Directors of the Peninsula and Oriental Steam Navigation Company obligingly send us the following:—"We have a wire of the following shipments of fruit: 'Per *China*, due here, about April 3, 6000 boxes; per Orient Company's *Oraba*, 6500 boxes; per *Massilia*, due here about April 20, 24,000 boxes."

COELOGYNE CRISTATA.—We have received during the past week, and by the same post, two photographs from gardeners, each representing successful cultivation of this pretty and useful species of Orchid. One of these comes from Mr. J. W. BARKS, Alderbrook Gardens, Cranleigh, Guildford, Surrey, and illustrates six fine, well-flowered plants. The other is from Mr. W. WEMMAN, Hickleton Gardens, Duncton. This shows a group of specimen plants in prize-worthy condition, that have been grown from small pieces by the present gardener. We regret that, having already figured many such instances in the case of *Coeologyne*, it is impossible for us to reproduce the photographs now sent.

CYDER AND PERRY FRUITS.—The season for grafting fruit trees is close at hand, and it would be well if those in suitable districts in the south who have Apple and Pear-stocks 1½ yr. planted would send to the Herefordshire, Somersetshire, and Devonshire nurserymen and farmers interested in the manufacture of these once national beverages for scions of the best varieties of each. We append the names of some of these, and doubtless the trade would furnish others equally desirable—

PEARS: PARSONAGE, Taynton Squash, Thora, White Squash, Moorcroft, as early varieties; Barland, Black Huffcap, Holmer, Winculs Longland, White Longland, Yellow Huffcap, and Oldfield, as mid-season varieties; and Aylton Red, Butt, Cuppy, Rock Red Pear, and Thurston Red, as late ones.

APPLES: *Herfordshire*, Dymock Red, Eggleton Styre, Forest Styre, Foxwhelp, Gemmet Moyle, Hagloe Crab, Kingston Black, and Red Splash. *Devonshire*,—Tom Butt, Red Cluster, Soldier, North wood, Pennal Apple, Bonford, and Sweet Elford. *Somersetshire*,—Black Hereford, Handown, Cainsby, Lanyer Bitter Sweet, Red Cluster, Sweet Robinette, &c. In the case of Apple and Pear-wilding stocks planted this year, and therefore unfit for grafting, budding should be carried out late in July, and in

August and September, obtaining the shoots on which are the buds from the sources indicated. These shoots, if carefully wrapped in damp moss covered by waterproof paper, could be safely sent in small numbers through the post. The west country farmers run up their Crab and Pear-stocks to a height of 6 to 8 feet, and graft at that height, which is doubtless of advantage in the case of varieties which make weak growth, or which seldom make sturdy stems; but it is not essential, as almost every kind of cyder Apple and perry Perry will make in time, if not decurved of its lateral shoots too severely, a stout stem when grafted or budded low down. The Arbor Day, inaugurated by Mr. RANCLYFFE COOKE at Eynsford on Saturday, February 27, should set all holders of land thinking, however small their holding may be, in what manner they may obtain a stock of dessert, culinary, or cyder and perry varieties of Apples, Pears, &c.

ENTRIES OF PLANTS AT THE ROYAL HORTICULTURAL SOCIETY.—Constant complaints having been made to the Council to the effect that the business of each of the committees has lately been disorganised, on account of the disregard of the Society's rules and regulations, the Council hereby direct, that—1. The rule whereby all objects presented for certificate must be entered with the clerks at the table before 11.30 A.M., be in future rigidly enforced. And that—2. All such objects must be placed on the special table provided for plants for certificate. After the plants have been presented to the committees, they can, if the exhibitors wish it, be incorporated in their groups.

ENGLISH ORCHARDS.

(Continued from p. 151.)

WEST OF ENGLAND.—The four great fruit-producing counties in the West of England are Devonshire, Hereford, Somerset, and Worcestershire, and it is in these that the greatest need for improvement exists. These four counties contain about 675 acres of orchards, notwithstanding the highly favourable character of both soil and climate, and the facilities that exist for the disposal of the produce, not one-fourth of this large area gives an adequate return. Here we find not only trees that are unproductive through age, starvation, or some other form of inefficient management, but thousands that in consequence of the inferiority of the varieties, bear fruit that is utterly useless, excepting it be to make bad cider. In the formation of many of the Apple and Pear orchards, trees that had sprung from the plists distributed through the medium of the refuse from the cider or perry press were planted, and these have remained until the present day giving neither pleasure nor profit to their owners, and without anything being done to improve them by the simple process of grafting. With regard to the capabilities of Hereford as a fruit-producing county, we are told that "almost every holding in Herefordshire could produce magnificent fruit for home use or for supplying the market if the trees were given proper attention, and the right varieties grown. The soil is naturally rich and fertile, resting on the old red sandstone in many parts of the county, and the colour of the fruit when ripe is very bright and striking." The manner in which the great natural advantages of the county are in too many instances refused may be gathered from the following statement in reference to the Loominster side of the county.

"With the exception of gardeners, no one appears to trouble much about the orchards, except when the hog-heap needs replenishing. Then the farmer turns his attention to his orchards, and the deal would be cut out of the trees, with, also, it may be, many of the large limbs. I never saw worse mutilated trees than those met with in one or two orchards. . . . Canker, American blight, lichen, deal wood, and general carelessness are only too apparent in almost every orchard. Young trees that should be producing full crops of the finest Apples may be seen in a dying condition, through sheep or young horses having onced on all the bark on the trunk. The free-growers are in many instances of the most primitive description, and practically worthless. Hundreds of young trees are literally choked by a mass of thorns or small branches of forest trees tied up in a bundle round the stems. This rough, unskilful method certainly answers the purpose of protecting the young trees from sheep, but it is a case of *1000 Nails, 1000 Hammers*, and other means which now my mind. This practice of tying up the young trees about as high as the trees, thereby forming all moisture from the roots."

With regard to the orchards in another part of the county, it is stated "I found on an examination trees only 1½ feet apart, and, as a matter of course, the best were literally overcrowded with each other. When the trees get into this very congested state, all the elements natural to fruit trees hold high revel, devouring foliage, blossoms, and

even the points of the shoots, until all the food at hand is exhausted. These wasted orchards are a standing menace to other growers who exercise proper care with their trees, as they are practically a nursery for all sorts of injurious pests, which spread and attack other orchards in the vicinity."

As Hereford has long been known for its cider, it follows as a matter of course there should be a standing menace to other growers who exercise proper care with their trees, as they are practically a nursery for all sorts of injurious pests, which spread and attack other orchards in the vicinity."

As Hereford has long been known for its cider, it follows as a matter of course there should be a standing menace to other growers who exercise proper care with their trees, as they are practically a nursery for all sorts of injurious pests, which spread and attack other orchards in the vicinity."

Devonshire has the largest acreage under orchards of the English counties, and consequently the report on the present aspect of fruit culture in this shire has special interest, and an excuse will be necessary for the two questions I shall make. We are told with regard to the capabilities of this county:—"By way of showing what it is possible to do in Devon, I give a few figures supplied by Mr. Snow, who has an orchard only one acre in extent, but which has been thoroughly well managed from the time it was first planted. In 1850, Mr. Snow grew 21 bushels of fruit to make 31 hogsheads of cider, which he sold at the rate of 5s. per hogshead. In addition he gathered and sold 500 score pounds of Apples, which fetched, on an average, 1s. per score. Good crops were again had in 1851, and 153 hogsheads of cider were made, this fetching 20s. per hogshead, while no less than 550 score lb. of Apples were marketed, this time at 1s. per score. It is the old tradition to the effect that some varieties of Apples only bear fruit once in every two or three years were true, then Mr. Snow ought to have had very few fruit in 1851, and not a very heavy crop in 1855. As it happens the trees are not in a crowded state, nor individually in want of thinning out, nor of being cleared of roots, nor in need of assistance at the roots, and, as a consequence, were fully equal to bearing an even heavier crop. Twenty-nine hogsheads of cider were made, and six hundred and fifty score pounds of Apples marketed." The way in which these capabilities have been taken advantage of may be gathered from this excerpt:—"Devon is certainly famous for its orchards, and is noted for the excellence of much of the cider that is made in the county; but the orchards will not, as a rule, bear critical examination, nor is cider sufficiently in demand to justify such a waste of space in growing Apples for its manufacture. As a matter of fact, Devonshire, compared with other counties, has made little or no progress of late years, and there are hundreds of orchards in that county that are a little short of disgrace to those who own or rent them. Here and there are signs of improvement taking place, and it is hoped the capable instructors engaged by the technical education committees will not expend their energies in vain. The majority of the trees in Devon are of the same kind, and are often the worst of gardeners and the poorest of fruit growers, and they cannot be induced to improve on their methods. All the while the trees remain standing that is sufficient for them, and not a few that have blown over—for they get some help in Devon—are left where they are as long as life remains in them, or the cattle that roam in the orchards leave them fairly intact."

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

ASPHODELINE TAURICA (*Kuntz*). (See fig. 52.)

This fine species from Asia Minor has a robust stem, which is densely provided with erect linear leaves. It ends into a long densely-flowering cylindrical raceme, with large ovate, or ovate-oblong acute or cuspidate pure white bracts, which enclose the flowers. The peduncles are short, articulate in the middle. The white perianth has linear spatulate leaves, with a brownish middle nerve. The filaments are very unequal, the longer ones have the anthers three times larger than those of the shorter ones. The plant grows in stony places of the sub-alpine and alpine region of Asia Minor, from where it was imported last year by Mr. Siehe, of Merina. *L. D.*

HOME CORRESPONDENCE.

SWEET PEAS.—In the *Gardeners' Chronicle* for February 13, p. 114, in an article on Holtzbecker's drawings he states—Sweet Peas are exceedingly small. I presume this remark refers to the two varieties of Lateirus on p. 40 in the *Album*. The two drawings in the centre are doubtless these in question, as figs. 1 and 4 are forms of Lotus. I hardly think figs. 2 and 3 are intended for Sweet Peas, as the plants in both cases are entirely different to any Sweet Pea I have yet seen. But I think fig. 2 is intended for *Nyctalus sativa*, introduced 1640 (Don); *vale* also *Nyctalus Dietl*, at *Lathyrus*. I enclose a dried specimen. The flowers are bluish-white, as in Holtzbecker. This plant is cultivated for forage in Western and Southern France, and other places on the Continent. I have not been able to clearly identify fig. 3, but presume it may be meant for *Lathyrus tuberosus*; a specimen of this is enclosed herewith. There is a small-flowered red, which I have often seen near the Basses Alpes, but it is one-flowered, and the keel is not pure white. I am sure your correspondent will be glad to have his attention directed to this. The second earliest coloured illustration of Sweet Peas I have been able to find is in Kniphof's work. Can you help me to find something earlier? In *Gerarde's Historie of Plants*, 1597, I find under *Lathyrus maior latifolius*, variety 3, the following:—"The stalks, leaves, and flowers of this, are like those of the precedent, but the flowers are of a reddish-purple colour; the pods are lesser than those of the former, and in them are contained lesser, harder, and rounder seeds, of a dark or blackish hue. This grows not wild with us, but is sometimes sown in gardens, where it flowers in June and July." Can you help me to the modern name of this plant? On the following page to the work, the number 3 is affixed to an engraving of *Lathyrus angustifolius* for, purple, or purple-flowered Cuckling Vetch. The engraving shows a plant very similar to the Sweet Pea, with leaves slightly elongated. Respecting coloured illustration of Sweet Pea, I had overlooked the fact that a figure of the purple variety appears in that charming set of engravings, designed by Peter Casteele, engraved by H. Fletcher, from the collection of Robert Furber, Gardener at Kenington, 1750—"Hunts from the Bissett Rigand, 1730." June plate, fig. 33; the brick red shading is obviously an artistic effect. A perfect copy of this work is to be seen in the reading-room of the British Museum. *D.*

LAPAGERIA ROSEA AND L. R. ALBA GROWING IN THE OPEN.—I have witnessed various kinds of treatment of *Lapageria rosea* and its variety under artificial heat, and in the open with a due precaution taken against injury by the sun's rays, but I have never seen such luxuriant plants as those growing in the garden belonging to—Robin, Esq., of Bishops Leighton, Devon. They are planted against a wall facing due east, with little over protection afforded them in winter than a frost light. The plants composed of the red-flowered rose and its white variety, and large umbrageous trees near at hand cast a umbrashade over the wall, and render the surroundings somewhat damp. Under these conditions, the plants, as I was told, flower profusely, although the local conditions are not very favourable, as was apparent from the scrubby appearance of the hedges and trees on the seaward side. *T. Brookbank, 39, Hoopern Street, Exeter.*

DAMAGE BY THE STORM AT WEST PARK.—The heavy gales of the 3rd and 4th inst. occasioned a great deal of injury to the trees in the grounds at West Park, Salisbury, amounting from 200 to 300 of them, and seriously damaging many more; some of the fine specimens of Cedar and Pines having suffered greatly, and Scots Firs of 80 to 110 feet in height were blown down, and the tops of others broken off. *G. Fulford, West Park Gardens, Wilt.*

THE AMERICAN APPLE CROP OF 1896.—I have been favoured by a correspondent in Pennsylvania with the following particulars of the Apple crop for 1896. It was fully 50 per cent. greater than that of 1895, indeed, the heaviest they have had for many years. The average price paid for selected Apples, without barrel, was 50 cents (about 2s. per three bushels, which is the quantity a barrel holds). The barrels cost, delivered at the orchards, about 25

cents each, therefore the price paid at the orchards was from 75 to 80 cents per barrel for choice fruit (75 cents = 3s.). The price paid for picking is 2 cents per bushel. In a young orchard where the trees were low and the crop heavy, a good picker might pick 100 bushels in a day. Choice fruit carried by boat 1200 miles to Memphis brought a dollar-and-a-half per barrel. At Cincinnati, Ohio, and Louisville they were a drug in the market, and dealers disposed of them at any price they could obtain. All cellars and buildings along the river Ohio were filled with Apples, being held back for better markets, but owing to much of the fruit rotting, but little will be realised, unless from regular storage houses like one in this neighbourhood which holds 40,000 barrels. This letter was dated January 26, and the temperature at the time was 17° below zero, Fahrenheit. *Mid Kent.*

COLD STORAGE FOR FRUIT.—During the discussion which arose after the reading of Mr. G. Gordon's admirable paper on English orchards, the necessity for cold storage of Apples, and fruit generally, to keep it marketable over a long season, and to check not infrequently gluts, was strongly urged. Many persons seem to be unaware of the fact that if we will but grow good, late-keeping varieties—Lane's Prince Albert, Wellington, Newton Wonder, Framley's Seedling, and others, as also some specially regarded as late eating varieties—there is very little difficulty in keeping them sound and fresh for several months, if properly stored. A good Apple store should be one which admits of an occasional change of air on cool days only. The walls and roofing should be so dense as shall always maintain during the winter an equable temperature; and where the atmosphere is rather moist than dry. Still, the average temperature should not be allowed to fall in any case lower than freezing-point, and may go as high as 40°. Concrete or mud walls and thatched roofs will often furnish this desideratum as less readily affected by fluctuations of heat and cold outside. But the advocates of cold storage seem to favour much lower temperatures than I have mentioned, and produced artificially. Now the point is, what would be the condition of fruit, Apples especially, subjected to a low temperature—say 30°, for a long time? How would such a temperature affect the flavour and quality of the fruit, and would good Apples or Pears be like after a few days' exposure to our normal and changeable temperatures? Has any one any knowledge on this head? *A. D.*

ARBOR-DAY.—I have read with interest your short notice of "Arbor-Day in Kent," and it seems to me that if 150 Apple, Pear and Plum trees have been thereby added to the orchard area in one rural village, the celebration has not been devoid of utility, and may very well be commended for imitation to country towns and villages, not only in Kent, but in all other counties of the kingdom. It is quite certain that, if Arbor-day were to prevail generally, nurserymen would everywhere find an increase in demand for fruit and forest-trees. There is wisdom, too, in having one day in the year (not necessarily the same day, nor even at the same season of the year in all places) set apart for planting. We all know how "stated time is a hedge to duty," thus, if it be once decided to give one day a year to the business of planting fruit and other trees, the effect will be to considerably improve the fruitfulness of our native land, and at the same time to add increased attractiveness to the landscape. The celebration in Kent seems to have been business-like. A resolution at a public meeting of the villagers in favour of "a commission to enquire into the condition of our orchards," strikes at the root of the mischief, which was the keynote of Mr. George Gordon's paper at the Society of Arts meeting on March 3. I observe that the *Gardeners' Magazine* neither favours the adoption of an Arbor-Day, nor thinks it likely that we shall obtain a commission to enquire into the state of our orchards; for what reason the one is disparaged, and the other despised, now being launched for the purpose of celebrating the present remarkable year of our Queen's reign; and, although loyalty is supposed to be the prominent motive, there is in connection with the movement far too much collection of *U. s. d.* Arbor-Day in Kent was inaugurated with comparatively trifling expenditure, and yet the effects will probably be felt for a century; every recurring season will witness an increase in the size of the ornamental trees planted by the children; and in years to come, villagers and wayfarers will enjoy the grateful shade as they gradually grow to maturity. Many a refreshing

FIG. 52.—ASPIDODELINE TAURICA. (SEE P. 171.)

being made almost like liquid, some jelly that is soluble at about the temperature of the hands is taken, and with a small ball of this the seeds are shaken in the hand, and then poured on to a glass plate. The jelly soon sets. In a few days the plants will appear, and then there is weeding only to be done, until all that are left resemble each other. The dust of the rooms and the atmosphere are full of these "weeds"—indeed, they are everywhere. But one plant can be isolated under the microscope, and made to grow continuously under observation there. In fact, it could be put in a microscopic greenhouse, which could be heated, illuminated, filled with any desirable gas—could, indeed, be used as, and serve all the purposes of, an ordinary greenhouse.

One of the principal questions regarding each organism was to determine whether it is a friend or an enemy. Recent developments have proved that microscopic gardening has been carried on for years by agencies and persons not fully aware of the fact. Artificial hybridisation was a case in point. In that case the stigma was the medium (soil), and the pollen the seed. The pollen-grains being placed upon the stigma, commenced to grow, and emit a tube through the style to the ovary; and there is one known case, at least, where the growth of such seeds is sometimes frustrated by the presence of weeds. The spore of a certain fungus is sometimes deposited upon the stigma of a particular plant at about the same time as the pollen-grain, and when this happens the spore which is first admitted into the pollen-tube with the grain do, but the tube of the fungus-spore invariably reaches the ovary first. These fungus-spores were brought to the stigma by bees, and bees were therefore the oldest microscopic gardeners. Of course the stigma of a certain plant was a suitable soil (medium), only for certain seeds. The first human attempt, Mr. Ward, knower of microscopic gardening was in relation to brewing. In this case the plant-bee was the wort, and the plants were certain organisms in the air which effected fermentation. This had latterly been turned to account, and brewing was no longer carried out in the high-brewing manner that preceded it, and the principles of the operation were not properly understood.

The ordinary soil of a field or garden was simply alive, and contained myriads of Bacteria, fungusespores, and other minute organisms. It varies greatly in the number it contains, even from 100 million to 100 billion in a cubic inch. It was found that the first 3 inches from the surface contained the greatest number, and they became gradually fewer until at about 2 feet there were none existent. What were these things doing? The work of many of these organisms differed much. One set would decompose paper, and render it food for the worms, and thus the same way with the case of farmyard-manure. Soil without such organisms would not support plant-life. Mr. Ward then referred to an organism that it was proved liberated nitrogen in the soil, and said that this in the future would probably explain the circuits of the nitrogen from plants and animals through the air back to the soil.

The rust upon Wheat was then referred to, the history of its identification hinted upon, and the practical value of the results from this knowledge. There were two stages in the history of these parasites—their life outside the plant, and their life inside the plant, and it was essential to know, in order to circumvent the disease, what was the most vulnerable moment of their existence. In the case of seeds which were mixed with or carried fungus spores, it had been found that the fungus seeds could be killed by hot water at a temporary rate that failed to injure the other seeds at all. In all antiseptic treatment, it had to be studied how to treat and kill the parasite without withering the host plants.

The general use and application of antiseptic measures were remarked upon, and Prof. Ward stated that notwithstanding the success that had resulted therefrom, more consistent success would be obtained if the measures were always intelligently applied, and the operators thoroughly acquainted how to apply them, and at what moment. The evidence in the laboratory was conclusive, but it was for the cultivators to experiment afterwards in order to see how far and under what circumstances the antiseptics could be applied in the garden without injury. By doing so they would considerably help the microscopic gardeners also in the laboratory, and the cultivators and the former should have many suggestions and ideas to exchange with each other. Unfortunately, said Prof. Ward, there had been some lack of interest in the subject. In conclusion, the lecturer said that he had been able to say only sufficient to explain the matter without going into details; but his paper, being too long to be read at the time, would be printed in the Society's Journal.

Rev. GEO. HENSLOW made a few remarks, and referred to the fact that Pliny had noted, that in the first century of our era leguminous plants were grown for the purpose of tanning in by digging, and only recently that we know why such a practice was scientifically correct and valuable.

HORTICULTURAL MEETING AT GHEENT.

AMONG the number of interesting exhibits seen at the recent meeting of the *Chambre Syndicale des Horticulteurs Belges*, the following plants may be mentioned:—

Dendrobium Kingianum, an Australian species, bearing many small flowers, an excellent greenhouse plant; *Cartudovicia palmifolia*, a very beautiful plant with deep green leaves still in perfect condition, its numerous adventitious roots and suckers give it a picturesque appearance, both these plants were from M. L. DE SARTT-DUVERNE.

Tillandsia Lindeni vera, is a dwarf variety, vigorous, and with three fine spikes of bloom; it came from M. JELLES DE COCK. *Mitoniopsis blueana* rosea, with three racemes of large, rather dark rose flowers; *Cyrtopelium Boxalli*, with fourteen well-coloured blooms; and *Odontoglossum hystrix* var., remarkable for its distinct lavender flowers, which came from M. JELLES VEE. *Vriesea Ledouinii* (Closely), spikes dark red, very shiny, with flowers very bright yellow at the bracts, and *Cyrtopelium villosum* × *Stoneli*, with petals like those of *villosum*, and the beautifully coloured lip distinguished by the unusual sight of its white bordering, were both shown by M. POELMAN-MANS. *Azalea* (M. J. BOUTMAN) was sent by M. J. B. BALSAN; the flower was large, handsome white, double, the petals slightly scalloped, an excellent variety. M. A. DALLIER exhibited *Dendrobium thyriformis* (Hillebrandt), with four flowering and three budding racemes. M. G. DE COCK showed *Clivia* *Mme. G. De Cock*, with a fine fruss of large well-developed flowers; *Dichroandra argentea*, a specimen with twelve spikes of fresh, foliage, and *Pandanus pacificus* with fine shining green foliage and of dwarf habit, both came from M. ALB. RIGOUTS. From MM. DEBIEZ FRERES came *Levistia rotundifolia*, a dwarf variety, fine and healthy; and from the SOCIÉTÉ HORTICOLE GANDOISE, a group of six seedling *Anthurium* of the Rothschildianum section which obtained the highest award, being excellent varieties, very effective, the spathe large and wonderfully varied in marking, some having small other large spots, and the colours also being white and of various shades of red.

At this Meeting a plan of the Hamburg Horticultural Exhibition was shown and much commented upon; the groups extend over 15 hectares (1 ha. = 2 1/2 acres), the lake over 6500 square metres (1 sq. m. = 1 1/2 yd. area), the great exhibition hall 8000 square metres. The halls for the permanent exhibition are 1500 feet long, these for the industrial section 975 feet; the flower-garden 77 feet by 260; various tents, refreshment-rooms, &c., are to be erected, and there are to be rosaries and a large fruit garden.

From the storms in Belgium on March 3, various horticultural establishments near Ghent, notably at Loozsticht and Murelbeke, suffered considerable damage. *Ch. De Boesche*.

NATIONAL CHRYSANTHEMUM.

MARCH 8.—A meeting of the general committee took place at Anderson's Hotel on the above date. Mr. T. W. SIBBALS presiding. A letter was read from M. Henri de Vilmorin, acknowledging the honour done him in electing him a honorary member of the Society. It was unanimously resolved that, in consideration of the honour done him by the hospitality shown to the recent deputation from the Society to the Ghent and other shows, a Silver-Gilt Medal of the Society should be presented for competition with Chrysanthemum at the exhibitions to be held during the present year.

Mr. G. E. WITTS, of East Finchley, was elected a member of the committee in the place of Mr. N. DAVIS, resigned. Messrs. E. BECKETT, W. MENGE, J. H. WITTY, T. BEVAN, G. STEVENS, and H. OWEN were re-elected members of the committee. Mr. C. COMBES, elected by rotation; Mr. H. WIGGS, Leatherhead, was elected in the room of Mr. N. DAVIS, who had resigned. Mr. T. BEVAN was unanimously re-elected chairman of the Floral Committee. The schedule revision sub-committee recommended the creation of two classes of "amateurs," one comprising those who manfully, if not entirely, cultivate their Chrysanthemums themselves, and who while employing not more than one assistant regularly, are yet the real growers and exhibitors of their plants. To this division nine classes are appropriated, an extension of the number which has hitherto found a place in the schedule; and single-handed gardeners would be allowed to compete in those classes that in no other division. The second class of amateurs would be the definition hitherto observed, and they have eight classes apportioned to them. The exhibitors in each case can compete in any of the table-decoration classes. This approved new arrangement appears to give much satisfaction to the large body of amateurs who are members of the Society. The Committee have also set apart three classes commemorative of Her Majesty the Queen attaining to the sixtieth year of her reign. One is for thirty-six blooms of Chrysanthemums, twenty-four Japanese and twelve incurved distinct novelties introduced in 1895, 1896, or not yet in commerce to be shown on ordinary boards for Japanese Chrysanthemums; all to be correctly named. This is open to the trade only. The other is for thirty-six blooms of white, yellow, and crimson Japanese Chrysanthemums, in twelve varieties, three blooms of each, to be shown on ordinary boards, with three inches of clear stem above the boards. The handsome Turner Memorial, which was not completed for use at the Exhibition is offered as a Challenge Cup in this class, and it is to become the property of the individual winning it: two years in succession, or three times in all.

The third of the commemorative classes is that for twelve of 40 distinct varieties of apples, nine of them to be varieties in cultivation in the country at the time of the accession of the Queen, the remaining fifteen varieties those introduced during the past thirty years, five fruits of each to be shown, and the varieties need not necessarily have been grown by the exhibitor. The schedule gives the names of thirty varieties in cultivation sixty years ago, and in which the Queen was reared, and the crown in the present day. The sum of £15 is given in five prizes.

It was resolved that the Classification Committee be continued during the present year, the appointment of the Catalogue Revision Committee being postponed for the present. It being considered some revision of the rules was necessary, a sub-committee was appointed to consider the matter, and report at a future meeting. Mr. J. T. SIMPSON offered a special prize of one guinea for the premier-Japanese bloom in the next November show; and, in addition, expressed his willingness to make a pointing in oils of the flower, and present it to the winner of the prize. The Secretary reported that there were at the present time 703 Ordinary, 163 Fellows, and 88 Foreign Members, making 842 in all; and 136 societies in affiliation.

UNITED HORTICULTURAL PROVIDENT AND BENEFIT.

MARCH 8.—The annual general meeting of members of this provident benefit society was held on this date, in the Caledonian Hotel, Adelphi, Strand. The chair was filled by Mr. A. DEAN, and there was a moderate attendance. The minutes of the last meeting having been read and adopted, the secretary (Mr. Collins) proceeded to read the report of the committee for 1896.

The accounts have again been carefully audited by Messrs. W. GUNNER and G. DIXON, and found correct. The committee specially invite all young gardeners and seedsmen to join this excellent society, feeling sure they cannot do better than join the "United."

The detailed balance-sheet was a most satisfactory one, and showed that there was a balance to date in favour of the benefit fund of £884 5s. 6d., a balance in favour of the benevolent fund of £294 5s. 6d., of the voluntary convalescent fund of £304 8s. 6d., and of the management fund of £44 14s. 7d., which, together with a balance carried from the previous year of £172 17s. 6d., makes a total of £1930 4s. 5d., being the assets of the society. The report and balance-sheet being formally proposed and seconded, was passed unanimously, in the absence of the slightest criticism.

The Chairman then delivered an address upon the aims of the society, and the singularly successful character of its operations. The advantages the institution offered was strikingly exemplified by the fact that Mr. J. GEORGE, being now 70 years of age, retires with a sum of £82 10s. to his credit—a circumstance that is probably without a parallel in similar institutions. Seven years ago the amount standing to Mr. GEORGE'S credit was about £40, and it had, therefore, increased during that time to the extent of nearly 424.

The membership of the Society in 1887 was 191, in 1890 it was 210, and since then it had risen to 641.

The election of officers was then proceeded with, and to fill five vacancies that occurred upon the committee, the following members were elected:—Messrs. Kelf, Regent's Park; E. T. COCKE; Hemsley, Edmonton Nurseries; Coles and Winter. The whole of the officers were re-elected.

NURSERY NOTES.

MESSRS. JNO. LAING & SONS.

AT the Stansstead Nurseries, Forest Hill, the work of raising seedling Begonias is in full progress. There are several houses filled with boxes containing seedlings that have been, or are about to be, pricked off; and whilst expressing astonishment at the numbers in such a stage, we were led by Mr. LAING into other structures in which were many more plants that had evidently been raised specially early. Some of these were in pots 6 and 7 inches in diameter, and had made sufficient growth that they are already flowering. Mr. LAING can tell us a very great deal of the early history of these glorious tuberous Begonias; for he was one of the first to set to work to produce them, using in the first instance the species *B. boliviensis*, *B. Veitchii*, *B. Pearcei*, and a few varieties. Their culture has ever since been one of his specialties, and though many growers have assisted in perfecting them since, Mr. LAING'S enthusiasm for the plants is as great as ever.

But though we had seen sufficient seedling Begonias one would think for almost any purpose, these were not all, and upon entering another of the low span-roofed houses that abut on to the potting-shed, there were half-a-dozen or more boxes engaged in "pricking off." As this work is done as soon as the first leaves appear, it is a very delicate operation. There must be no undue hurrying, nor do the boys touch the tender seedlings with the hand. Under the eyes of a foreman they sit down, and each takes a box filled with a suitable compost. In the left hand he holds a tiny wooden dibber, and in the right a forked stick, and with these he transfers the plants

from the seed-bed (also a box) into the fresh compost. If there has been too great a liberality in the sowing of the seeds, this becomes evident at the present and subsequent stages, and there will be all the more need to hasten the work of transplantation. But constant practice in this and similar work prevents such mistakes from being frequent in a nursery.

In another department, work has been occasioned by the Caladiums, most of which are now commencing to grow freely. If nurserymen were always to tell their own secrets, we should probably hear that the Temple Show being held so early in the year as May, obliges them to make the very most of every bright spring day that occurs. This season, however, February has been a mild month, and such plants as Begonias, Caladiums, and many others that have to make their entire growth after Christmas will have a comparative opportunity.

That the season is by no means late may be observed in the Clivia-house, for here the plants are already partially in bloom, and in a week at least there will undoubtedly be a good show. These crosses of Clivia are quite worthy of recommendation, as greenhouse plants, they afford good quantities of bloom with very little trouble, and require but a small amount of heat. Indeed, a little frost does not appear to kill them; but if secure from this they are happy, and there are few more suitable plants for an ordinary dwelling-house window. The latest novelty Messrs. Laing have amongst the Clivias is the variegated one. Several plants of this variety were in bloom, and seeing that throughout the year the variety has some merit as an ornamental-leaved plant, and that it will flower also each year, it may in time become popular. There were some of the varieties in flower, including Patrick Davidson, Princess May, and Stanstead Beauty. Lady Wolverton, and Advance, too, both of them good ones, would open their flowers soon; and Glow, one of the highest-coloured. Prince of Wales, Mrs. Jno. Laing, and Jno. Laing, are capital varieties, but flower a little later. There there is a new one, named after the Right Hon. Joseph Chamberlain, M.P. This is said to be of much merit, and will be in flower shortly. In the stove is being effected the propagation of such plants as Crotans, Dracaenas, Soncerilas, and a host of species, including the pretty Saxifraga sarmentosa tricolor variegata. In another house are batches of Cinerarias and Primulas in bloom. Dahlias and Cannas, Carnations and other plants, are in various stages in pits and frames; and spring-work of divers nature in each department is observable.

AMERICAN NOTES.

THE WINTER MEETINGS OF HORTICULTURAL SOCIETIES.

ALMOST every State in the Union, and each of the southern provinces in the Dominion, has its own horticultural society. The principal meeting of each society is usually held in the winter, continuing two to four days. The attendance at these several meetings is most thoroughly representative of the best horticultural interests in the land, and the topics discussed are the best possible index of general thought and progress. Most of the meetings for this year have now been held. In spite of discouraging, and sometimes disastrous, markets, the attendance and the interest in these meetings has been larger than ever.

Two new societies of some promise have been organized in the eastern states; one in Vermont, organized December 3, with Mr. T. L. Kinney as president and Professor F. A. Waugh as secretary; and the Hudson Valley Horticultural Society, to embrace eighteen counties in eastern New York, organized at Poughkeepsie, February 3, with Mr. James Wood as president and Mr. E. Van Alostyrne as secretary. Both these societies have the room and the opportunity for success.

Probably the strongest of the fruit-growers' organizations is the Western New York Horticultural Society, which held its forty-second annual

meeting at Rochester this year. One of the most interesting subjects presented on that occasion was that of thinning Apples. The 1896 Apple crop was extremely heavy. Mr. S. A. Beach, of the Geneva (New York) Experiment Station, in cooperation with neighbouring fruit-growers, made several tests to determine the value of thinning the fruit. For instance, Baldwin's thinned to 4 inches apart gave 22 per cent. more of No. 1 fruit than trees not so treated, though the total crop was reduced 26 per cent. One tree of Rhode Island Greening, from which only the inferior fruits were removed early in the season, showed an increase of 6 per cent. in the total crop, and of 10 per cent. in quantity of No. 1 fruit. Hubbardson's Nonsuch, thinned to 6 inches apart, bore 25 per cent. less fruit, but 17 per cent. more of No. 1 fruit. At the same time other advantages were secured, such as improved colour, better quality in the fruit, and better health in the trees. Some of the trees on which the thinning was practised have formed many fruit-buds, and promise a crop for this year. Mr. Beach and the co-operating orchardists think the method practicable in commercial orchards under most circumstances.

Another important meeting was that of the Michigan Horticultural Society at Grand Rapids; at this meeting Mr. John Craig, horticulturist at the Central Experimental Farms, Ottawa, Ontario, reported very interesting experiments with cover crops in orchards. Most of the commercial Apple orchards in America are cultivated several times in the spring. By sowing some cover crop at the last cultivation, the deleterious action of the sun and air on the soil is avoided, alternate freezing and thawing are prevented, and, when turned under, they supply some quantity of plant food and increase the organic matter in the soil. They also keep down weeds. Leguminous crops are especially desirable. Mr. Craig tested Crimson, White, Red, Alsike, and Mammoth Clovers, Alfalfa, Peas, orchard Grass (Dactylis glomerata), and some mixtures. The Mammoth Clover gave best results. Peas were second best. The Crimson Clover sown July 13, gave a crop of 22,234 lb. green material per acre, containing 17 per cent. dry matter. Mammoth Clover gave 13,210 lb. of green material per acre, containing 21 per cent. dry matter.

These and similar reports at the various horticultural meetings emphasise the refinement of methods now developing in all American horticultural industries—a refinement which has received special impetus by reason of the recent heavy crops and glutted markets.

ELECTRO-GERMINATION.

Mr. Ass S. Kinney has just reported through the Hatch Experiment Station (Massachusetts) some interesting experiments in the use of electric currents upon germinating seeds. These experiments indicate that the useful strength of an electric current acting on seeds, lies within very narrow limits; that such currents do not lose their effect, but may act as a constant stimulation to growth and development; and that, in some cases, an actually larger percentage of germination may be gained. In seeds receiving a strong current, there was an increase of 30 per cent. in the length of the radicles at the end of seventy-two hours; though at the end of ninety-six hours, the difference in favour of treated seeds was reduced to 15 per cent. The gain in growth of hypocotyls by use of an "optimum" current, was only 13 per cent. F. A. Waugh, Burlington, Vt.

NEW YORK BOTANIC GARDEN.

Mr. Samuel Henshaw has been appointed head gardener to the recently-established New York Botanic Gardens. Mr. Henshaw is a native of Manchester, and was for a time in the service of the botanic garden of that city. He migrated to the States in 1868, and devoted much of his attention to landscape gardening. *Our Own Correspondent.*

AMERICAN FOREST RESERVES.

We learn that one of the last acts of President Cleveland was the establishment of a number of forest reserves in the Western States and territories. They embrace a total of 21,000,000 acres, and con-

prise all the important timber-growing areas in the West belonging to the Government. This step is the result of the persistent work and unflinching insistence of Professor Sargent. Its importance to the States can hardly be over-estimated.

Obituary.

CHARLES SHARPE.—The death occurred somewhat suddenly, at Sleaford, of Mr. Charles Sharpe, a well-known seed merchant and agriculturist. Mr. Sharpe was a magistrate and alderman for the Kesteven Division of Lincolnshire, and also President of the Lincolnshire Agricultural Society for the present year. He had twice unsuccessfully contested constituencies in the county. In agricultural and horticultural circles he will be well remembered for the active part he took in 1869 in promoting the passing of the Adulteration of Seeds Act, and its Amendment in 1873.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 49° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

DAYS.	TEMPERATURE.				RAINFALL.	BRIGHT SUN.
	Above 49° for the week ending March 6.	ACCUMULATED.

- 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.;
- 10, Ireland, S.; "Channel Islands."

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending March 6, is furnished from the Meteorological Office:—

The weather during this period was very unsettled and stormy, with considerable falls of rain during the greater part of the week, and heavy showers of hail, sleet, or wet snow towards its close. Thunder and lightning occurred at times in many parts of the kingdom.

The temperature was rather below the mean in most districts, but just equalled it in the Midland Counties and England, N.W.; and slightly exceeded it in England, S., and E. The highest of the maxima were registered on somewhat irregular dates, and ranged from 52° in England, S., to 49° in England, N.E. The lowest of the minima were recorded, as a rule, about the middle of the week, when they ranged from 19° in Scotland, E., and 21° in Scotland, N., to 18° in England, S., and to 25° in the Channel Islands.

The rainfall exceeded the mean in all districts excepting

'Scotland, N.' Over Ireland and the greater part of England, the fall was very heavy, amounting to about four times as much as the mean over the central and southern districts. In 'Scotland, E.' the excess was very slight.

"The bright sunshine was deficient in most parts of Great Britain, but exceeded the normal over Ireland, and also in 'England, E. and N.W.' and 'Scotland, W.' The percentage of the possible duration ranged from 23 in 'England, E.' and from 30 in 'Scotland, W.' and 32 in 'Ireland,' to 15 in 'Scotland, E.' and 17 in 'Scotland, N.'"

POTATOS.

Supplies very heavy, and prices still dropping. It is difficult to get orders for inferior samples. Dunbar, 300, to 3s. to 3s. 6d.; Saxons, 6s. to 7s.; others, 5s. to 6s. John East, Wellington Street, Covent Garden.

SEEDS.

LONDON: March 10.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maize Pond, Borough, London, S. E., write that there is now naturally more business passing in seeds; nevertheless, when the land recovers from its present seriously swollen condition, an increasing number of orders will come to hand. Prices all round continue at the low level characteristic of the present season. Tares realise former terms. There is no change in either Lucerne or Sanfoin. Some American Lima boiling Peas just landed, being good & cheap, attract attention. Canary seed is steady. Hemp and Millet unaltered. Peas and Haricots, and Linseed strong.

FRUIT AND VEGETABLES.

LIVERPOOL: March 10.—Prices current to-day at the following markets:—St. James's, Potatoes, 8s. to 10s. per peck; Asparagus, 6s. per 100; Cucumbers, 1s. each; Grapes, English, 3s. 6d. per lb.; do., foreign, 8s. to 10s. do.; Pines, English, 4s. to 8s. each; Mushrooms, 1s. 3d. per lb.; Birkhead—Potatoes, 6d. to 10s. per doz.; new, 3d. per lb.; Cucumbers, 6d. to 1s. each; Grapes, foreign, 8s. to 10s. per lb.; Pines, English, 2s. to 5s. each; Mushrooms, 1s. per lb. North Hay—Potatoes: Imperators, 1s. 6d. to 1s. 10s.; Giants, 1s. 6d. to 1s. 10s.; Main Crop, 2s. 3d. to 2s. 6d.; Chamois, 1s. 8d. to 1s. 10s.; Braes, 1s. 10d. to 2s. 3d. per cwt.; Turnips, 10d. to 1s. per 12 bunches; Swedes, 1s. to 1s. 3d. per cwt.; Carrots, 3s. to 3s. 3d. do.; Onions, English, 4s. to 4s. 6d. do.; do., foreign, 2s. 0d. to 3s. 7d. do.; Cauliflowers, 1s. 6d. to 2 6d. per doz.; Cabbages, 6d. to 1s. 6d. do.; Celery, 6d. to 1s. 3d. do.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending March 6, and for the corresponding period of 1896, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1896.		1897.		Difference.
	s. d.	s. d.	s. d.	s. d.	
Wheat	25	4	28	3	+ 3 1
Barley	21	5	23	0	+ 1 7
Oats	13	8	16	3	+ 2

APPENDIX.—GERMINATING APPARATUS. The designer of the germinating seed-apparatus which appeared in our pages on Feb. 27, is Dr. H. F. Jokinan, of Utrecht.

ARUM: H. W. S. As you say, the spathe has not decided whether to retain its leafy condition or to become white, like a petal. As it is, it is half one half the other. The flower looks as if it had experienced a check at some early stage of growth.

BLACK ORCHID FROM MALAYA: Goodenopsis. We are quite unable to say what this is. It may be a B. bophyllum. It will want considerable heat, and abundance of water when growing.

BOOKS: The Pincian, by G. Gordon, published by H. G. Bohn, Henrietta Street, Covent Garden, 1880. The Forester, by J. Brown, revised by J. Nisbet; published by W. Blackwood & Sons, Edinburgh and London.

CHRYSANTHEMUMS FOR FLOWERING IN THE OPEN: H. A. See the calendar article for the Flower Garden in our issue for March 6, 1897.

INSECTS: J. L. The soil is swarming with Daily-long-legs grubs ("Leather Jackets"). You will never be able to grow Iceland Poppies nor anything else in it. Carefully remove it all and burn it, and replace with clean stuff. R. McL.—F. A. True weevils, very destructive. Trap them with slices of Carrot or Potato, and catch them at night.

JAPANESE CHRYSANTHEMUM: A. H. Very remarkable, but perhaps hardly so appreciable in March as in January.

NAMES OF FRUITS: H. J. Wheeler. Apples: 1, appears to be a well-kept Blenheim Orange; 2, Striped Beefing.—J. B. T. Dutch Mignonette.

NAMES OF PLANTS: Correspondents not answered. In this issue are requested to be so good as to consult the following number.—S. C. Jayam. We are pleased to be able to render assistance to one at such a distance, but specimens sent loose in a letter were smashed so as to render identification diffi-

cult. No. 1, which you say you have as Cyripedium Hookeri, is the much rarer C. purpuratum; No. 2, C. javanicum, No. 3, a very fine variety of C. insigne.—J. S. M. Daphne laureola.—R. M., Southampton. 1, Goldfussia isophylla; 2, Epipedium pinnatum; 3, Elegans pungens aurucovarietatis; 4, Ilex creata, a small Japanese Holly.—Brighton Court Hort. Co. A very fine form of Dendrobium nobile, large and very brightly-coloured, a good feature being the colouring at the backs of the petals.—L. L. Cattleya Triandria deliata.—W. E. The white one is Odontoglossum crispum; the spotted a very pretty form of O. Andersonianum.—A. P. 1, Cymbidium pendulum, illustrated in the Botanical Magazine, t. 387, as Epilidium albidus; 2, Alouosa incisifolia.—E. A. T., Brighton. A very pretty variety of Dendrobium nobile, a form of M. Juniperus abnna, very peculiar.—C. W. D., 1, Dentaria glandulosa; 2, Scopolia viridifolia.

PLANTS FOR WEST OF SCOTLAND: W. H. M. Enkianthus japonicus, Ribus vernicifera, Nandina domestica, and Glycyrrhiza japonica, are sufficiently hardy if afforded protection against the winds that blow from the colder "airs." Ternstroemia indica, and Lagerstroemia indica are too tender.

ROYAL GARDENERS' ORPHAN FUND. We have the pleasure to acknowledge the receipt of the sum of £s. from Mr. G. Garner, of Galloway Park Gardens, Southampton, in aid of this charity.

SEA-KALE RUNNING TO FLOWER WHEN 3 INCHES HIGH AND FORCED: Perpleced. You omitted to cut over every crown at the ground level last spring when the forcing was over. It is tough, and takes a long time to cook because the warmth with which you force it—60° to 65°—is nearly 20° too low, if it therefore grows very slowly. By-and-by it will grow at that degree of warmth and less, but out of season more heat must be employed.

STACHYS TUBERIFERA: A. C. Plant at any time during the present month in shallow drills, covering the tubers with about an inch of soil. Let the drills be about 10 inches apart, and the sets 6 to 8 inches. Nothing new is needed during the season but to keep the ground clean. The tubers are fit for use in late autumn or winter, and they should not be long exposed to the air before cooking, or the colour will be bad.

TWELVE VARIETIES OF CHRYSANTHEMUMS FOR MARKET PURPOSES.—Précocité Delaux, Mille, Thérèse Reu, Vivand Morel, Chas. Davis, Louis Boehmer, Florence Davis, W. H. Lincoln, Canary Yellow, very late; Source d'Or, Bouquet Fair, Cullingford, Lyceroff Glory. If you like paired varieties, choose any of the Queen and Empress section, John Salter, Barbara, Jardin des Plantes, &c.

VINES AFTER TEN YEARS' CROPPING: Perpleced. We imagined that the mistaken practice of affording vines the carcasses of animals as plant-food was long since exploded. It is far too strong a food for the vine, or, indeed, any kind of plant; and doubtless if you will examine the border where the cation lies buried, no roots of the vines will be discoverable. Clear out the border entirely, covering the soil with quick-lime, and then with 2 feet of sweet mould—it will make in a few years a dressing for your lawn, or a quarter of the kitchen garden that is in need of manure and deep trenching. Vines for early forcing should be in vigorous health, a state not consistent with the absence of roots in the inside border. The whole of the arrangements seem to require overhauling. It may, indeed, be found necessary to plant new vines, as well as make new borders.

COMMUNICATIONS RECEIVED.—W. B. U. D., Berlin. Prof. Kew, and Messrs. B. S. P. & Co., Ltd., H. D. H. H. M. R. L. H. J. J. W. E. J. W. W. F. L. — Agri-Horticultural Society of India.—Capt. John Walker and W. C. next week.—B. S. Williams.—J. Carter & Co.—G. H. M.—H. C. F.

CONTINUED LARGE INCREASE IN THE CIRCULATION OF THE "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardener's Chronicle" has, since the reduction in the price of the paper, increased to the extent of more than 90 per cent., and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among country gentlemen, and all classes of gardeners, and has a very large foreign and colonial circulation, and that it is preferred for reference in all the principal libraries.

THE

Gardeners' Chronicle.

SATURDAY, MARCH 20, 1897.

SOWING AND TRANSPLANTING.

THE season has arrived, and this year somewhat earlier than usual, when the cultivator must take advantage of every occasion when (or if?) the dry state of the surface-soil permits, to prepare it for the reception of seeds of many kinds of garden crops, and of plants and tubers. This preparation consists of pulverising the clods left by the winter, digging by means of the digging-fork, mattock (the three-tined mattock used in Kentish Hop-gardens—a very handy tool), and heavy hoe. The idea is to bring every particle of the tilth, or "till," into contact with the air, not a difficult matter after a frosty winter, and when the usually drying winds of March have acted on the purposely rough surface left at the winter digging or trenching. The amount of labour spent in the operation varies a great deal, it being usually a light job on light loams and peaty soil, and heavy on clayey, tenacious loams, or those in which the water-level is at but a small depth; and in the case of the latter, it is seldom that one operation is sufficient to provide the needful fine tilth that small seeds and plants must be provided with if success is to reward the cultivator's efforts.

In the case of land, which when dug was laid in ridges, the latter have to be levelled and spread about, not a difficult matter even with the stiffest soils if the frosts have been severe, but one that requires much labour if the winter has been wet and mild. If the ridges run north and south, the sides are equally dry and amenable to the pulverisators, but it is otherwise when these run east and west, the sunless slope being usually wet at an early part of the spring; and in the case of stiff soils, it must be levelled and allowed to lay exposed to sun and air for a week or longer time, or it can be incorporated with the rest of the surface-soil. Hence, to form ridges in this direction is a mistaken practice on almost any kind of soil that would be better replaced by flat-digging or trenching; it is also inimical to early growth if Potatoes are set in furrows running eastward. Some of the seeds sown on land thus early prepared, consist of transitory crops in the sense that for convenience sake in some cases, and for case of protection from birds or frost in others, the seeds are sown somewhat thickly broadcast, or in drills in beds, the seedlings being transplanted when of sufficient size to be readily handled.

In this manner, Cabbages, Kales, Brussels Sprouts, Savoys, and Cauliflowers, are raised, but there are no other reasons than those named, why in gardens with sufficient fallow land, and where very close cropping is not called for, these seeds should not be sown where the crops are intended to mature, thus saving

the labour of transplanting and watering, and ensuring stronger and more vigorous plants. Transplanting is by no means essential, and is frequently the direct cause of sundry ills. The gardener seldom transplants the Turnip, the Beetroot, the Parsnip; and rarely does he transplant Parsley, Scorzonera, or Rhubarb, and he finds it better practice to sow Summer Lettuce where it will stand to mature, avoiding transplantation in this case because it favours bolting or running to seed. The successful transplanting of these plants, which have taper roots, involves the complete preservation of the tip of the root, an essential matter, by the way, with Ten-week and other Stocks. It is especially necessary with Beet, Parsnips, Parsley, and similar plants. But transplanting means an expenditure of labour both before and subsequently. Might we not avoid this and sow our Cabbages, Savoys, Kales, Cauliflowers, &c., in little groups of three or five seeds in line, and thinning to the strongest one in each patch? We should require to purchase seeds, perhaps, rather more freely, but their cost would be recouped by the lessened expenditure on labour, or rather, by the ability to employ the workman at jobs which otherwise must be let alone, or done very perfunctorily.

How many gardeners see in the check caused by lifting and trimming Celery when transplanting it from the seed to the nurse-bed, a reason for its untimely bolting? The plant is a biennial—that is, if it be sown one year, it will bloom the next; why, therefore, should it, in garden parlance, "bolt" in rudiment, unless it be, that by reason of the loss of its roots, nature makes an effort to multiply its kind in anticipation of early extinction? The bolting of Cabbages may be traceable to the same cause. Sowing in the trenches, or in the case of early Celery in small pots, would remove one of the causes of the partial loss of crop from bolting at an early stage of growth. A few seeds only need be sown in each pot, the weaker plants being removed, as it becomes apparent which is the strongest, transplantation taking place in June without disturbance of the roots. The same kind of treatment would suit the Leek, although this plant has such a wealth of roots, and is not tap-rooted, that the check inflicted by transplanting is but little felt, at any rate, it is not a cause of premature flowering. So much, as indicating the directions in which departures and innovations are called for in kitchen garden practice. When we come to deal with the plants of the flower-garden, we find none of those hard-and-fast rules prevailing so commonly followed in the former. Seeds are sown where the plants are to bloom, and thinning, more or less—unfortunately, it is commonly less—is carried out with results commensurate with the intelligent care exercised by the gardener in his treatment of them. But the rough treatment accorded—say, to a Broccoli or Cabbage plant in the stress of high summer, when it is dragged up by main force, it may be from a hard, dry soil, and set out in the blazing sunshine in a shadeless quarter or a field, is never meted out to an Aster, a Ten-week Stock, a Carnation, or even the well-rooted Marigold, most gardeners knowing full well that failure awaits that kind of treatment of these plants. Pricking-off whilst still quite young, into pots and boxes, and early transplantation with a suitable ball of soil to each, is the usual practice; with the result that there is no premature flowering, and, barring the effects of the season, the plants flower at their looked-for season.

Regarding the sowing of seeds of culinary vegetables, it is necessary, as formerly, to have an annual rotation or change of crop. Long-continued experience had taught the cultivator ages ago that a plant abstracts something from the soil, of which there is, comparatively speaking, but a limited amount—it may be nitrogen, phosphoric acid, potash, &c.; and that to continue to crop the land with the same species resulted in light crops and deteriorated produce.

Science has, however, ascertained by analysis of many of the plants the gardener and farmer grows, the chief constituents of these, and indicated those substances or those manures which present the greatest amount of the elements of which the plant consists. Does his plant show a large proportion of nitrogen, he can purchase nitrate of soda, or make use of rich manure from the fattening oxen-sheds (not cow-manure, that being notoriously deficient in nitrogenous matter). Is it lime of which the plant-analysis shows considerable quantity? he has then crude lime, or the more easily assimilable super-phosphates—either bone or mineral. Is a plant rich in potash as, say, the Strawberry and the Potato? he can apply that substance direct to the crop in one or more top-dressings afforded during the growing season.

Having all these and other readily-applied aids to field and garden culture, the reason for rotation has become less urgent; and the gardener, for example, who has a limited area of "south border," and yet is desiring to have early Strawberries, Potatoes, Tomatoes, and Cauliflowers, may rest assured that he may crop this land for many years without changing the position of any one of them, and without the land becoming "sick," if he will only afford each kind of plant its proper food, and carry out the proper methods of cultivation which experience shows the plant requires. Only in the case of Peas can continued cropping of one quarter in a garden be overdone, the amount of nitrogen left in the soil by the roots rendering it at least unfitted to maintain a crop of leguminous plants of any kind. To restore such land to its normal condition it is prudent to grow upon it such plants as will make large demands on the nitrogen stored up in it, and such are Cabbages, Cauliflowers, Onions, and Celery, among the commoner vegetables.

NEW OR NOTEWORTHY PLANTS.

MICHAUXIA TCHIHATCHEWII.*

THE technical description below given, together with the illustration (fig. 53), will suffice to indicate what a noble plant is here offered to the cultivators of hardy plants. The plant grows at an elevation of about 5000 feet in the Cilician Taurus, so that it may be presumed to be hardy. It is described as a biennial. The photograph, from which our illustra-

* *Micbauxia Tchihatchewii*, Fischer et Meyer, *Ann. Science Nat. ser.* 4, l. p. 32. "Plant covered with spreading hairs, stem tall, subso-diplosid, simple, leafy at the base, above terminated in a long, subracemose spike; leaves dentate, the lower ones broadly oblong, untrifoliate or lobed at the base, narrowing into a short petiole; outline leaves oblong and ovate, amplexicaul; flowers two to four (white), subsessile, fasciated, lower fascicles shortly stalked, upper ones sessile, clustered; bracts broadly cordate, triangular, ovate, acuminate, clypeo-segment and appendages broad, and shortly lanceolate, very striate, the appendages twice shorter than the sepals; corolla short, glabrous, setose along the nerves, divided to the middle into oblong, linear, ultimately spreading segments.

Habitat among rocks in the mountainous part of the Cilician Taurus, &c.

"Plant 6 to 7 feet high, with a peduncular spike 2 feet and upwards in height; radical leaves, with the petiole often about 1 foot long." *Transacted and adapted from "Bioscop. Flora Occidentalis,"* iii. (1875), p. 292.

tion was taken, was sent us by Dr. Dammer, and was, we believe, taken on the spot by Herr Siehe, by whom seeds were introduced to the Erfurt firm of J. C. Schmidt.

Eulophiella Peetersiana, n. sp., KrcL.*

This is indeed a great novelty—great in two senses—as a plant, and as a charming novelty. The size is about the same as that of a large *Grammatophyllum*, which this plant also resembles by some other characters. The rhizome produces many roots which creep over the trees. The creeping stem is 2 to 6 cm. thick (three-quarters of an inch to 2½ inches); the bulbs reach the enormous size of 28 cm. in length; they are a little compressed, and like the stems, are covered by the remains of decayed leaves. The flower-stalk is said to be 100 cm. high (about 40 inches); it bears in a close raceme twenty to twenty-five very beautiful flowers of the size of 7 cm. (2¾ inches). The dorsal sepals and the petals are obovate, and rounded at the top; the lateral sepals are broadly-linear or oblong, with nearly parallel borders; the lip is large, the side-lobes broadly-oblong, the middle one divided into two little ones; the disc bears at the very base a three-lobed callosity; the radiating nerves are thickened throughout the whole lip, and deepened—especially the middle ones—into sharp-angled triangular lamellæ. The colour is certainly a very beautiful rose-purple; the lip has a great golden-yellow blotch in the middle. Twenty or more flowers of such a size and such a bright colour must produce a very lovely sight.

About five years ago I learned from the late Johannes Braun—who died afterwards at Antananarivo—that he had discovered a giant Orchid not belonging to the *Angraecoids*. He sent only two (huge) leaves of about 60 cm. in length. To judge from the bases of leaves of my specimens, I believe he saw the plant in question; and the bases of the latter agreeing well with the leaves I have in memory. The plant was now found by Mr. Mooris, sent to Mons. Peeters at St. Giles, near Bruxelles. I have received materials from Mr. F. Sander and Mons. Peeters. *F. Kraenzlin*.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM × SCHNEIDERIANUM.

This is one of the choicest of all the *Dendrobium* crosses, viz., *D. Findlayanum* × *D. aureum*, and is getting somewhat widely distributed. The raiser, Mr. Wm. Holmes, who was gardener at the time to Mr. Schneider, Fallowfield, and subsequently to the late George Hardy, of Pickering Lodge, Timperley, tells me that he has not been able to get up any seedlings since his first success at Fallowfield, although he has had capsules and even embryos in an infant state, but these all died. The first capsule produced a variety of forms, all more or less beautiful, but some of the varieties bring much larger prices when disposed of than others, particularly those possessing the deep orange tint so admirably seen in *D. aurea*, and which carry flowers of good size. No one flower is considered first-rate by an expert unless it is 3 inches in breadth, and has sepals, petals, and lip of a nice form and good substance. One of the most striking is in the collection of R. Ashworth, Esq., the Ashlands, Newchurch, Lancashire (gr., Mr. Pidsley). This plant has the habit of *D. Findlayanum*, and approaches it in size; only it has not the rich orange of *D. aureum*, which is noticeable in some varieties, neither is its lip puckered-in or "pinched," like that of *D. aureum*. The plant in question bore about a dozen flowers, and is in fine health.

The position of the sepals is singular, the centre one standing erect, the inferior ones instead standing at a depressed angle, as is frequent in *Dendrobies*, and sweeps round to a right angle. The flower shows a nice flushing, in which white and pink commingle; petals obovate, nearly white, unless at the extremity

heavily tinted with blush; their breadth 3 inches, each individual petal 1½ inch by about ¾ in width. The lip is broadly and roundly ovate, two-thirds of its surface of a yellowish shade rather than an orange,

and having a broad margin of white, which stops short at the yellow lines. At the base are two crimson dots, and at the extremity of the limb is a pink-coloured blotch. *J. A.*

FIG. 53.—*MICHAELIXIA TOCHTATHEWII*; HARDY BIENNIAL; HEIGHT 6 TO 7 FEET; FLOWERS WHITE. (SEE P. 181.)

* *Eulophiella Peetersiana*, n. sp., KrcL.—Caulis longe prorepente, infra radicibus crebris arboribus affixo, crasso 2-6 cm. diam., apice in bulbum maximum transiente, omnino cataphyllis et supra foliis vestito; bulbo longo ad 28 cm. fistulato subcompresso vestigis foliorum omnium annulato; foliis? certissime maxillis; seapo 1 m. alto valde; racemo plumbico (20-25) bracteis; floribus magnis rosopurpureis 7 cm. diam. sepalis dorsalibus petalisque subulnatis subulnatis et basi sassis lata obovatis antice rotundatis, sepalis lateribus basi ipsa partim connatis late ligulatis apice obtusis; labelli latissimi foliis lateribus late oblongis obtusis, intermedio multo minore bilobo, callo lobulati caroso tripartito, lineis per discum omnibus incrassatis antice in lamellas triangulas acutis, lamellis medianis maxillis antice acutangulis; gyno-gonio 7 sepalis dorsalibus sequente. *F. Kraenzlin*.

A WELL-FLOWERED DENDROBIUM NOBILE.

We learn from the *Bradford Observer*, that at the residence of Mrs. Knowles, Hollin Hall, Moorhead, Shipley, there is a plant of *Dendrobium nobile* bearing at the present time 1134 blooms. The plant, which is a very fine one, secured a Certificate of Merit of the Bradford Paxton Society last year, but it is in infinitely finer condition now. It is practically circular in form, with a diameter of 5 feet. The correspondent who furnished the paragraph states

of the lip. During the winter other nearly white forms have flowered, including *V. teres aurora*, which has very large flowers, but not so good in form as the pure white one now in bloom. Whereas the large rosy-crimson form grown at Tring is constant in flowering with great profusion during the early summer months, the white or nearly white forms flower at odd times during the winter and spring, although they frequently flower again at the same time as the coloured variety. There promises to be a grand show

them. The species *D. Mezeureum* is a native of Britain and other north temperate countries, and is well known as a dwarf shrub with fragrant flowers, which appear in February and March. Its three varieties, viz. *alba*, *rubrum*, and *autumnale*, are less common in gardens, although meriting cultivation for the sake of variety.

Our figure was taken from a photograph of a plant growing in the garden of W. Marshall, Esq., Auchinraith, Bexley, Kent.

FIG. 54.—*DAPHNE MEZEREUM ALBUM*, GROWING IN MR. MARSHALL'S GARDEN.

that five years ago the plant was in wretched condition, with scarcely a decent pseudo-bulb; by skilful treatment the gardener, Mr. Moorly, has not only resuscitated the plant from certain death, but brought it to its present condition. There are four more plants in these gardens, and the aggregate number of blooms on the five plants amount to 2758. I think for a smoky district like Bradford, Orchids will thrive and flower well if treated properly.

VANILA TERES CANDIDA.

In the house devoted entirely to *Vanila teres* in Lord Rothschild's gardens, Tring Park, a beautiful snow-white form of *Vanila teres* is in bloom, the only colour in it being a tinge of yellow on the side lobes

this year, and the immense plants of *Phalenopsis* in the adjoining house are now safely over a protracted, if not severe, winter, and also promise well for bloom.

DAPHNE MEZEREUM ALBUM.

The genus *Daphne* consists of about forty species, some of which are evergreen and some deciduous, with generally fragrant flowers. Some of the species are tender in this climate, as, for instance, *D. indica rubra*, figured in our last issue as grown at Berkeley Castle; and others, like the subject of our illustration (fig. 54), are so hardy that no frost hurts

NOTES ON NARCISSI.

(Continued from p. 152.)

PLANTING. LIETINS, & Co.—The importance of early planting is not generally understood. It is a convenience to the dealers to send out, and to gardeners to receive, bulbs of Narcissi with those of Hyacinths and Tulips in October; and a large dealer lately told me that he reckons to receive fully half his orders for Narcissi in November and onwards. It is outside my subject to discuss the cultivation of spring-flowering bulbs at large, but there are reasonable grounds for the opinion that they are commonly planted far too late. It is not easy to understand

low rooting can be comfortably accomplished when they are put into soil chilled by autumn frosts and sodden with autumn rains. The simple experiment of planting one row or clump of bulbs in August, and another from the same stock of the same variety in October, and observing the respective plants, flowers, and increase, will prove a convincing argument, certainly as regards Narcissus. It is to be remembered that the bulb has a twofold task of reproduction—the perfecting both of seed and of those independent buds which we call bulbs. This double work it cannot accomplish in full, unless thoroughly established with an ample equipment of feeding-roots before winter. It has been proved in my own garden that bulbs planted in August will yield offsets of full blooming size, while the same variety planted in October will scarcely give detachable offsets. Moreover, the bulbs deteriorate by waste of their vital stores if kept out of ground more than about two months. The Narcissus naturally emits fresh roots very soon after flowering, N. poeticus in particular often making roots of considerable length by the first week in July. The bulbs can be said to be at rest only during the short period of the yellowing of the foliage; they should be lifted before it disappears, both to anticipate the fresh growth, and to prevent injury by the fork—the leaves, of course, indicating their exact position. The precise date will vary with locality and season, but my own lifting is always completed by the end of June. The foliage should be cut off at the neck, and the bulbs not exposed to the sun, but spread out thinly to dry in cool, airy quarters. They heat quickly if left in heaps, and the slightest heating is sufficient to destroy their vitality. In about three weeks they will be dry enough for the old roots to be removed, and the offsets separated without tearing the basal plate. With some kinds—e.g., *N. maximus*—great care is needed to prevent this injury, and it is sometimes safer to cut than to break away the offsets. The old roots, too, of some sorts are wiry and tough, to avoid injury to the base the pull in removing these should be upwards, i.e., towards the apex of the bulb, and not downwards—or they may be cut off. It is a temptation to increase the stock of choice varieties by forcibly separating small offsets which are still contained in one tunic with the mother-bulb, and attached to it by a large segment of the base. Such young offsets have a large number of delicate roots embedded in and nourished by the old bulb, and to detach them prematurely is hurtful, and analogous to the cutting away of Strawberry runners, &c., before they are independently rooted. The criteria of excellence in Daffodil bulbs are, weight for size, a clear bright skin, and a base small in proportion to the largest circumference of the bulb, with a large quantity of fine, union-like roots. Where bulbs are not home-grown, but purchased, the small base may be taken as a proof that the roots were of this character. Here it may be observed that a change of stock is extraordinarily beneficial in the case of Narcissus; a grower literally by the million for the cut flower market has assured me that he was satisfied it would well repay the cost of carriage to exchange his entire stock annually with some distant grower.

Annual lifting and replanting is here prescribed only for the high cultivation of the Narcissus, i.e., in separate quarters, and for the production of the finest possible flowers. For such results it is necessary; but in good soils undisturbed clumps in mixed borders or in grass will retain a decorative beauty for many years.

August, as already said, is the best month for planting, but the latter half of July is not too early for beginning with the varieties of *N. poeticus*. In the large flower-farms, planting is usually done by the plough; in private gardens, the quarter should be divided into long beds, not exceeding 4 feet 6 inches wide, somewhat raised, with dug-out alleys in wet soils. In a well-known Daffodil nursery, the following Dutch fashion of planting is now adopted. The first of a series of narrow beds has the whole of its soil removed to the depth at which the base of the bulbs is required to be buried, a sprinkling of bone-meal is

given, and the bulbs set out in rows on the surface. This bed is then filled in from bed No. 2, and so on through the series. This method can be followed only in such loose sandy soils as are easily handled, on others the bulbs must be either trenched or dibbled in. My own collection—a very large one—is always planted with a dibber of about 7 or 8 inches insertion, the bulbs being first stood in lines drawn 9 inches apart, and the narrow way of the beds, for convenience in hoeing. The bulbs need not be more than 2 or 3 inches apart in the rows. With practice, there need be no fear of their being “hung,” and they can in this way be planted very rapidly. On my own soil I find it beneficial in dry weather to consolidate the ground by treading after planting. The subsequent cultivation consists of hand-weeding, surface-manning if necessary, and frequent hoeings after the plants appear. *G. H. Englehart.*

CULTIVATION OF ALPINE PLANTS ON WALLS.

MANY tender alpine plants which are difficult to grow here will only succeed in clinks of walls or crevices of rocks. In England, thanks to a damper atmosphere, plants from alpine pastures or glacial moraines do well, while a great number from high altitudes damp off, and cannot withstand the winter. Especially is this so with species bearing dense rosettes, which rot easily; for instance, *Androsace helvetica*, *glacialis*, *pubescens*, *pyrenaica*, *cylindrica*, *Charpentieri*, *Heeri*, *Draba tomentosa*, *Eritrichium nanum*, *Campanula pauciflora*, *Saxifraga cæsia*, *squarrosa*, *aphylla*, *steno-petala*, and certain species of *Sempervivum*, as well as plants which cannot stand damp, as *Campanula petraea* and *Tchihatchewia isatidea*. These are all pretty, and such as all would like to bloom. Many English growers try to keep alpine plants through severe winters. They cover them with a sheet of glass, or even put them in a cold frame to protect them. For years I have advocated the plan of growing delicate plants on walls, and I know that in England, where tried, it has been found more or less successful. A vertical position is not always so suitable for plants as it seems. Many of the more tender plants will grow upon rocks; for instance, *Ranuncula*, *Haberlea rhodopensis*, *Omphalodes Lucicæ*, and many other pretty species grow naturally in such habitats. *Saxifraga longifolia*, *Cotyledon cæsia*, *squarrosa*, *calceiflora*, and many neighbouring species, grow naturally in rock fissures. Also *Tchihatchewia isatidea*, a beautiful Crucifer, with scented rose-coloured flowers; *Matthiola valisaiaca*, saxatile *Campanula*, and many other pretty species from mountain rocks, succeed here at Geneva on walls, where the sun is powerful, and the winter less damp than in England. The well-known and rare *Saxifraga florulenta* can also be grown thus. It grows on the outer wall of the Boissier garden at Valleyres-sous-Rames (Vaud), it has been there since 1877, and seems to be quite established. Many plants of it bloom and seed (the plant is an annual, and dies after fruiting). Those who know the difficulty of growing *S. florulenta* will appreciate this. Other species might be cultivated in this way, such as *Eritrichium nanum*, which likes a dry and sunny place, dry in winter, moist in summer. On the high Alps, on steep rocks and dry nooks, this plant grows in light, sandy, pebbly soil, poor in humus. It does well in the sands of glacial moraines or the rocky debris of sharp slopes. It is found plentifully on dry peaks of the granitic Alps, but only in poor and arid soils. It dies, with us, not only from damp, but from a too rich soil, which produces too robust a growth. Ten years ago I recommended an English friend to plant the species in the clinks of a wall, in full sun and a dry place, with very little soil about its roots; this he did, and some years ago I found he had a nice lot of the plant in full bloom. Unfortunately, I can only get the plant to seed when grown in sphagnum, but at Bourg St. Pierre, in the Valaisian Alps, it seeds and 1 propagates itself freely. Possibly in England it would fruit better, the air being more favourable.

Among other plants which under these circumstances might thrive in England are the saxatile *Androsace* and *Campanula*, *Antirrhinum azurina*, and glutinosum, *Sempervivum*, and other species, which dislike damp. There is no need, when placing plants in a wall, to insert soil; water, air, and the erosion of the stone by the roots, with the necessary amount of moisture, provide all the nutritive ingredients necessary for saxatile species, many of which are certainly killed by too abundant nourishment. *H. Corveon, Jardin Alpin d'Acclimatation, Geneva.*

FORESTRY.

TREATMENT OF PLANTATIONS WITHOUT REGULAR THINNING.

THE 20-feet openings mentioned in my former paper, 1894, were cut in May, 1895, in the line of the rows of trees as planted, leaving 80 feet of the plantation untouched between each pair of openings. The only trees taken were Larch. In August the dead branches that were not worth faggotting were raked into the middle of each opening, and burned by a careful workman. He then made three rows of pits 6 feet apart in each opening with a roofing tool, and picked out the roots of the trees which had been cut down. Early in November he and I planted Silver Firs at 12 feet apart in the centre row of pits, and Beech in the others. A few Silver were planted in parts where there were forest trees. The total number of trees planted was 200 Silver Firs and 540 Beech.

In June, 1896, I only found four trees dead out of 740. This is partly owing to the earth in the pits being moist with the autumn rains, partly owing to shade from the trees on each side, though the weather continued very dry for a period of four months. My workman missed clearing up one of the openings, and in this one the young trees did not do so well, as the dead branches were not burned, nor pits made in the summer. It is an expensive way of working, but I think it is worth the expense to get good growth. I also hauled the poles down in an expensive manner. Four men, with two ropes round the head and foot of each pole, dragged them down to the roadside, without injuring the bark on any of the trees that were left standing. Some of the trees by the side of the road through the plantation had the bark torn off in strips more than 2 feet long by the haulers who removed the poles after the sale.

The following is a statement of the cost of cutting, burning, hauling, &c., and details of receipts for material sold:—

Labour, cutting, and letting poles	..	£6	6
Advertising sale	..	4	0
Burning dead sticks and making pits	..	0	13
740 trees	..	1	6
Planting	..	1	5
Faggotting	..	1	9
		£14	13
Received for Poles, 20 dozen and 7	..	£21	5
Faggots	..	1	7
Total receipts	..	£22	13
Cost	..	14	13

Net receipts for about an Acre of Poles, 38 years planted £7 15 11

A miserable return from an out-of-the-way plantation, with a steep hill on both sides. Cullington is the nearest town, about four miles distant. *Henry Rogers.*

TYPES OF BRITISH WOODLAND.

(Continued from p. 59.)

oak woods and cores.—Of all British forest trees, the oak is probably the best known by the public at large, if not by sight, at least by repute. “Hunts of Oak,” “The Haunted Oak,” and numerous other terms and expressions found in poetry and fiction, testify to the familiarity which exists between

this tree and those who know next to nothing of trees in general. The Oak has always been regarded as an emblem of British character, and perhaps many regard it as something as peculiarly British as our roast beef or our fox-hunting, unmindful or ignorant of the fact that the Oak might be quite as appropriately termed French or German as British. But in spite of this, it cannot be denied that Oak woods, or at least woods in which Oaks predominate, are the most typical of what may be termed the more natural or indigenous woods of England and Wales; for all our surviving fragments of old forests, whether parks or woodlands, consist largely, if not entirely, of this tree, and it makes little difference whether the site of the forest is located in the rich soil of the Midlands, or on a poor and exposed hillside in Wales. No soil or situation comes amiss to the Oak, for although it requires a deep and good soil to bring it to that size and maturity with which its name is usually associated, yet it will live and assume a healthy appearance on the thinnest soil, or in the crumple of a bare rock. As a timber tree, however, it is only on the better soils that we meet with it to any extent, and on clays and heavy loams in most parts of the country it prevails in all the older and middle-aged woods. It seems very probable that the mode of raising the majority of Oak woods in olden times was that of sowing the acorns on the spot, although many woods doubtless date back to the old natural forest which existed at one time in every district, being simply fenced off from the grazed or cultivated land as occasion arose. Many of the latter are practically in the same condition at the present day as when enclosed, renewing themselves from acorns, and mixed with Hazel, thorns, brambles, and various other shrubs indigenous to the soil. The presence in many of them of old pollarded stumps, confirms this view of their origin, although in the majority, modern views and methods of treatment have brought them from their unsophisticated wildness into closer resemblance to planted woods. To the naturalist and lover of Nature unadorned, this kind of woodland is regarded with great favour, while it makes the best possible game-cover. But it seems a pity that good fertile land, as many of these woods stand on, should not be made more profitable for the owner, and add something to the national wealth, which with more economical treatment, they might easily do. The planted or sown woods are generally fairly well stocked; with a sprinkling, or in some cases, fair crop of Hazel underwood, the latter being regularly cut over for hurdle wood, &c. Like most British-grown timber, however, the trees are usually too knotty and branched from unrestricted growth, an evil which at one time had its compensating advantages in the shape of knees for ship-building and hough-bark for tanning; but the demand for the former has almost disappeared; and the value of the latter greatly decreased of late years. Oak timber, like that of most other trees, is now of most value when straight and clear, and a little drawing up when young is as necessary as with other species if good results are to be obtained. Owing to its comparatively slow growth, Oak has been little planted of late years, as a glance at our young plantations throughout the country will prove. To those looking for quick returns, Oak is not an attractive species, perhaps, as its timber is never likely to want a ready market when of good quality; and those who plant, as most planters do, for a coming generation, would do well to give the Oak a place in the soil which suit it. On lighter soils, *Q. sessiflora* is considered the best adapted for producing good timber, although in certain districts it is rarely if ever seen. In the New Forest, we believe, it is the prevailing species; but *Q. pedunculata* in most districts is most common, and succeeds best on heavy ground. The practice of harking Oak continues, for the low price obtained still pays for the felling of the trees, and this is a consideration where a large quantity is in question, although the seasoning of harked timber is rarely so well done as when the trees are winter-felled. *A. C. Forbes.*

(To be continued.)

ENGLISH ORCHARDS.

(Continued from p. 174.)

FORSYTH, &c.—Much of the finest state of things exist in the orchards of Somerset, which ranks next to Hereford in the area under fruit trees, and with reference to these it is stated, "Somerset, all things considered, is one of the most fertile counties I have yet passed through, and in the matter of climate there is also little room for complaint. Yet, curiously enough, several kinds of hardy fruit have to be imported—Plums and Damsons chiefly from Worcester-shire, and Cherries from Kent." Also "great areas are devoted to cider Apples, which produce heavy crops; but they are of little value, and not well fitted for an immense improvement in the manufacture and increase in the consumption of the beverage can there be any profit from cider." Worcester-shire has the next largest acreage of fruit, and with regard to the farm orchards we are told—and this is the last extract from the reports that I shall trouble you with—"In no case did I find the average tenant farmer almost of the times in the matter of orchard management. These men's ideas are immovable, as their actions are generally confined to the practice of sticking in a tree in the position occupied by one that has fallen into decay. Trimming appears to be quite neglected by them, and the trees in the majority of cases are in such a unsatisfactory condition that no possible system would possibly so restore the fertility of the orchards as to ensure fruit of such quality as to sell at a price in the open market with foreign productions." I should like to speak in some detail of the condition of the orchards in Beds, Berks, Bucks, Essex, Cambridgeshire, Leicestershire, North, Norfolk, and other counties; but time presses, and I have already said sufficient to show that the English orchards are, in the majority of cases, in a condition that renders it impossible for the trees to produce

FIG. 55.—FLOWERS OF DAURIAN MEZEREUM ALMOND. (SEE P. 181.)

fruit worth sending to market or worthy of the purchaser's attention, should the owner be unwise enough to consign it to a salesman.

PROSPECTS OF REVIVIFICATIVE CULTURE.

It might well be asked at this point whether the possibilities of profitable fruit culture in England are such as to justify a serious attempt to renovate the orchards capable of being brought into a productive state, and replace those where renovation is practically impossible with new ones. In case this question should be in the mind of any member of the audience I will at once give an answer, and this must be in the affirmative. Assuming fruit to be an important article of food, and a plentiful supply over the longest possible period desirable, it will be readily admitted that it would be very much better for the farm-orchard to be in a condition to supply the household with an abundance of fruit during nine months of the year than for the farmer to have on his holding a large number of unproductive trees, and have to purchase at the nearest town or village foreign fruit, either fresh, dried, or in tins. This is not the principal aspect of fruit growing, but it is one that deserves the instant attention of both the tenant and his landlord, and also of the several bodies which exist for the encouragement and improvement of rural industries. The most important aspect of orchard management is unquestionably the production of fruit for profit, and with reference to it I have no hesitation in stating that, carried out on proper lines, it will give a good return. In making this assertion, I must not be understood as being in sympathy with those who would have us believe that it is possible to make a fortune in a short time from a few acres of fruit trees. What I submit is, that under proper management, orchards will be at least as profitable in proportion to their area as any other crop that can be grown. They should give a far greater profit than the best of the farm crops, and add materially to the value of the holding; but it will suffice for the purpose of my argument to submit that while worthless orchards are

unprofitable, those in good condition give an ample return for the initial outlay, and the expenditures incurred in their management. There are, of course, a large number of both tenants and landowners who are ever ready to contend that there is no profit in orchards, and to declare "that you cannot restore the prosperity of agriculture with a few pots of jam." But these will also tell you that "the farmers cannot be made rich with a few pots of jam, or a few fowls," and such catchy phrases may appear to those who have bestowed no thought upon the subject to dispose of the question. Let us see whether the culture of fruit, the making of jam, and the keeping of poultry would, if properly carried out, help the farmer to contend with the difficulties inseparable from the low prices of his staple crops, and that I should trouble you with a large array of figures, but shall confine myself to those found in last year's official returns, as they are quite sufficient for my purpose. Those show that the value of imported fruit was £5,900,069; of poultry, £265,458; of eggs, £1,154,577; and of hutter, £15,344,083, making the respectable total of £27,359,578. I do not suggest that the whole of this sum could have been retained in this country, but I submit that a very large proportion would have been, had those concerned fully informed themselves in past years as to the possibilities of the demand for these so-called minor articles, and the best means of supplying them. The demand of good quality, and in the most attractive and convenient form. I am now only concerned with the amount we pay the foreign growers for fruit, for the greater part of the supply might, and indeed, should be, produced in our own orchards and plantations.

With regard to Apples, the imported last year 6,177,192 bushels, of the declared value of £1,523,711, and I submit that a very small proportion of this enormous quantity should have been required from the foreign and colonial orchards. In case anyone may be inclined to question this assertion, I will at once state that in no other country are the conditions more favourable for the production of Apples of the finest quality than are those which obtain in England. For proof of this, it will suffice to point to the splendid Apples that are produced in gardens where the trees receive proper attention, even in districts that are not particularly favourable to hardy fruit; it is not the soil or the climate that makes us so largely dependent upon the foreign growers for our fruit supplies, but the apathy and ignorance of our cultivators. The lamentable state of our orchards is one proof of this, and the wretched manner in which the principal part of our fruit is placed upon the market is another. Next to there is a want of care in gathering and packing, but fruit is sent to market without regard as to the season, and, in consequence, the late Apples that may be had in perfection until March or April, are sent to market in the autumn, with the result that the prices of the early varieties are unduly depressed, and the markets are almost wholly dependent upon foreign supplies after the first of September.

In formulating a scheme for the improvement of English orchards it will be convenient to divide them into three groups. The first to comprise those consisting of trees so old and exhausted that their restoration to vigorous health and productiveness is impossible; the second, orchards in which the trees are in robust health, but represent inferior varieties; and the third, those orchards which contain moderately young trees of good variety that have been allowed to become unproductive through neglect. There is but one way of dealing with the orchards belonging to the first category, and that is to sweep them away, and plant in their stead with new orchards formed on some other part of the farm. To attempt to renew worn out orchards by planting young trees in the positions that were occupied by those which have died out, as is so generally done, is worse than useless, for it is a rare occurrence for trees so planted to be of any value as fruit producers.

In dealing with orchards containing healthy trees of inferior varieties, the obvious remedy is to graft them with varieties that are well known for their productiveness and the high quality and good appearance of their fruit. In the western counties, where the climate is the most favourable cultivated in orchards, as proved by the remarkable development of trees of very varieties, I would suggest that a considerable proportion of the healthy trees now bearing fruit only suitable for the perry press, should be grafted with such excellent varieties as Louise Bonne of Jersey, Belle Galignan, William Charles, and the late Duke of Devonshire's Hardy, Doyenne du Comice, Marie Louise, Marie Louise d'Urcle, and Josephine du Malines, care being first taken to ascertain by inquiries made in gardens which of the varieties will succeed in the district. Stewing Pears are not less profitable than dessert varieties, and the variety of the Cradle's St. Germain, and the Verulam, which are the best of them, are good bearers, and the fruit is available for the market during a period of six months, commencing with October, and can be sent long distances without special difficulty.

From the Apple orchards the hundreds of inferior varieties, whether belonging to the Cradle's St. Germain's St. are rare bearers, and produce fruit of good appearance and high quality, and of these there is an abundance. I would advise, also, that the area of many cider orchards, which in the western counties, form, it is computed, about four-fifths of the whole, be reduced in area, and the trees occupying more than a thousand acres with dessert or cooking varieties (such as an excellent beverage when properly made, but we are now concerned with making the orchards as profitable as possible, and it is obvious that Apples worth from £10 to £20 per ton are more profitable to grow than those which will not realise more than from £1 to £2 per ton. It is also evident that to obtain a full return from their orchards

farmers must grow both late and early varieties, and adopt some inexpensive method of storing the fruit of the former until after the early supplies have become exhausted. The most profitable of the cooking varieties are Bismarck, ecklinville, Plumelow's Seedling, Gascoyne's Scarlet, Golden Spire, Lane's Prince Albert, Lord Suffield, Newton Wonder, Pott's Seedling, Tower of Glass, and Warrant's King. Then of the dessert varieties I would recommend Blenheim Pippin, which is slow in coming late bearing when planted as an orchard standard, but grafted on large trees it quickly becomes productive, and the fruit, by reason of its handsome appearance and high quality, invariably commands a good price. Cox's Orange Pippin, one of the most profitable of dessert Apples in districts favourable to it, and when the fruit is properly marketed, Duchess of Oldenburg, an early variety which has a short season; Devonshire Quarrenden, useful for planting within a short distance of the market; King of the Pippins, and Worcester Pearmain. These form but a small proportion of the Apples in the catalogue, but before we can make our orchards profitable, we must follow the example of the American growers, and instead of planting two or three trees each of a hundred varieties we must plant a hundred trees each of a few varieties, and these of the very best.

(To be continued.)

NURSERY NOTES.

MESSRS. D. & W. CROLL, BROUGHTY FERRY.

Those who have had the pleasure of seeing their Roses in the first rank at our horticultural shows are naturally desirous of seeing the plants at home; hence, towards the end of the month of January last, I accepted the cordial invitation of Mr. James Simpson, the managing director of Messrs. D. & W. Croll, the famous Rose growers of Broughty Ferry, Dundee. I have seen their Roses on various occasions, and heard of medals, cups, &c., won by them at Newcastle, Oban, Aberdeen, winning over fifty prizes from some half a dozen acres of ground situated within sound of the sea or the mouth of the river Tay, which is probably rougher and more generous with its distribution of salt spray than the ocean itself.

It so happens that my last day among the Roses was in that unrivalled Rose-growing centre, Colchester, at the famous Colchester Rose Show, with the two Cants—uncle and nephew, and Mr. Prior.

With fragrant memories of those wonderful Roses in the east, I turned to Broughty Ferry Rosary with characteristic misgiving. My first question to Mr. Simpson was as to what Teas he found able to withstand the salt spray, and such storms as wrecked the Tay Bridge only a short way off? Before he had time to answer, we were walking up the rosary, and past a brake of Marchal Niels already pruned, the long shoots pegged down within an inch or two of the ground, and the spaces between top-dressed with rich half-rotted manure. The date of these proceedings was January 27, 1897. What protection do you give the tops of your Roses, Teas or others? The answer was emphatic—none. I have tried once or twice, with the result that those protected either were injured or killed outright, while those unprotected took no harm. I have, therefore, entirely ceased to cover or coddle, and truly not a handful of bracken or bough or any other litter was visible.

I remark in the weather reports that Aberdeen, which is about seventy miles further north-east from Broughty Ferry, has had the thermometer at zero since my visit. It would be interesting to know whether the Messrs. Cocker, the Rose growers near the granite city, cover their Roses or not, and if not, how the Teas, and especially Marchal Niel, withstand the extreme temperature. Mr. Simpson is also a strong believer in early pruning; in fact, they were busy with pruning and top-dressing the Roses towards the end of January. He anticipates no harm from early pruning, nor early growth; the chief danger arose from copious bleeding when pruning was at all late. I have often contended that the time to prune was all as the mode or measure of it is largely a matter of locality. But I confess it was quite a surprise to me to find the pruning of Teas and other Roses in full swing on January 27, 1897. The Roses, however, looked pictures of health and full of promise of beauty and fragrance.

The seedling Briar is also used as a stock for Teas, and young or yearling stocks are preferred. These take the buds on more readily and surely than stocks of larger calibre and greater age. Nothing could exceed the robust health and vigour of this fine stock of Teas Roses. The perpetuals looked equally healthy and vigorous. I understood that

not a few of the finest blooms were cut from maiden buds worked a few months previously, that is during the current season. In many cases, when buds broke into shoots and potential blooms, soon after insertion, the shoots of the stocks were pegged down close to the ground, thus throwing the force of the whole plant into young shoots of the bud, a plan that seems to answer better for the prompt development of truly maiden blooms than the entire removal of the Briar or stock shoots close to its union with the stock. Hence, in some quarters in these nurseries a twofold process of pruning was proceeding simultaneously, the removal of the wilding stocks, and the pruning back of the maiden shoots which had already maiden blooms of superb quality.

The process of planting seedling Briars and stocks was also proceeding briskly in various directions, one break alone containing some 10,000 stocks; and others equally large, as well as large quarters, some of which were sown with seeds, and all of them finished with all the care of a choice Onion-bed. From the few plants left unsold that were observed, two facts were manifest, viz., that the Broughty Ferry Roses are equal to those coming from some 400 or 500 miles further south; and that with all the efforts of Rose-growers, the demand for good Roses in the North, as in the South, still exceeds the supply. Practically the varieties from North and South are identical, as will appear from the few examples cited from standard and yellow Roses grown here:—La Belle Lyonnaise, Catherine Mermet, Gloire de Dijon, Jean Ducher, Madame Cusin, Marie van Houtte, Niphotes, Perle des Jardins, Rubens, Souvenir d'un Ami, and The Bride. Of yellow Roses I may name Belle Lyonnaise, Madame Welch, Celine Forestier, Marchal Niel, Etoile de Lyon, Marie van Houtte, Gloire de Dijon, Perle de Lyon, Jean Ducher, Perle des Jardins, La Boule d'Or, Revo d'Or, Madame Bernard, Madame Caroline Kuster, Triomphe de Reims, and Madame Margottin.

Mr. Simpson thinks if there is any difference in hardiness between Teas and hybrid perpetuals, the Teas are the hardier. Like most of our more famous rosarians, the Messrs. Croll also believe in a change of land for Roses. The veteran rosarian of East Anglia was one of the first to rest his Rose-land with crops of Barley or Oats; and it was a special pleasure to find part of the rotation crops in the Broughty Ferry rosary consisted of Narcissus and other bulbous plants, all of which seemed to thrive admirably in the sandy loam which, with the aid of manure, grows many of the finest Roses in the country, as well as plants of the most promising quality. D. T. F.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WAITE, Orchid Grower, Burford, Dorset.

Cattleya-honor.—Cattleya gigas, C. Warneri, and C. Rex, although they may be in active growth, should be kept in a moderately moist condition at the root till the flower-sheaths are perceived, when a gradual increase of heat and moisture are needed by the plants. There should not be a disturbance of the roots by repotting, the best time for this being at the season when the flowers fade and growth is finished, as then these Orchids send out roots from the base of the new pseudo-bulb. It is of importance to afford them every ray of light in order to bloom them satisfactorily; but all the same, if scorching of the leaves is feared, then some thin material must be used to shade the plants.

C. Doriana, and its variety *C. D. aurea*, now starting to grow, may be afforded similar treatment, but a few grees more warmth during their season of growth do good. Plants of *Cattleya Percivaliana*, which having recently passed out of bloom, will be emitting fresh roots, and then is the time to repot any plant in need of greater space, not delaying till the roots have grown much, or many of them will get injured. Most of the *C. Trianae* are approaching the end of the flowering season, rendering more care necessary in affording water to the roots, as too wet a compost will rot the older roots. Till growth begins, it is safer to lean towards the dry side. Those plants of *C. Mendellii*, *C. Mossie*, and *C. Lawrenceana*, on which the flower-buds in the sheath are prominent, should be afforded rather more water at the root till the blooms expand. At this season *Cattleyas* should be examined every day for the destructive *Cattleya-fly*, careful watching at this period probably saving the life of some valuable plants. The fly almost always pierces the young

growths when these are a few inches high, producing an abnormal swelling at the base of the growth, and a tapering to the apex. When thus affected the growths make no further progress, and the only course to take is to cut off the entire growth and forthwith burn it, cure there being none.

Thunias.—*Thunia* Bousouin, T. Marshalli, T. pulchra, T. Veitchiana x, T. alba, and T. candidissima, may now be shaken out of the old compost and repotted. In general, these plants are cultivated seven or eight together, in an 8 or 9-inch pot, which is a convenient method where space is limited. The pots should be almost half-filled with crocks, then a layer of turfy-loam, the rest of the space being filled with peat and moss in equal proportions. The advantage of having turfy-loam below the compost, is that the roots find their way into it just previous to the appearance of the flower-spikes, and derive benefit from it, and it affords vigour to the growth. To be successful in blooming these plants, they should be firmly potted, and afforded as much sunlight as possible; it is therefore proper to place them with the tips of the bulbs nearly touching the roof-glass of the stove or East Indian-house. The young growths revel in the sunshine. When the repotting is finished, let each bulb be secured to a neat stick; and for the next few weeks, or till growth is started, and the bulbs are making roots, water should be sparingly afforded, but afterwards it may be freely supplied, and quite re-established plants are benefited if diluted cowshed drainings be occasionally given instead of clear water. In the earlier stages, the young breaks are apt to get infested with thrips and a species of yellow-coloured fly, both of which must be sought for daily and destroyed, or much damage will be caused.

PLANTS UNDER GLASS.

By G. H. MACOCK, Gardener, Lantoo Hoe, Luton.

The Treatment of Plants after Forcing.—Plants of *Deutzia gracilis* should have the shoots that have carried bloom severely pruned back, each shoot being taken separately and cut back more or less according to its strength, the weak shoots being the more severely pruned; weak flowerless spray at the base of the best shoots should be cut off at the ground level. After pruning, stand the plants in a forcing-house, syringing them abundantly every day; and when the weather gets milder turn them out into cold frames to continue their growth, with the help of manure-water occasionally, and a daily syringing.

In June the plants should be transplanted to the rims of the pots in beds of tanners' bark or coal-shales, and sufficiently wide apart for the sun to shine on all sides of the plants, where the growth will be fully made and matured. If any of the plants need repotting, or the drainage put in good order, a suitable time is when the shoots begin to break after the pruning.

Azalea mollis and *A. rustica* (Ghent).—Both of these species, in their numerous varieties, will produce good heads of bloom, if not quite equal to imported plants, if the plants after being forced are taken proper care of. When the bloom is over, they should be repotted in a mixture of peat and leaf-mould, with plenty of sharp sand mixed with these, and encouraged to make growth by placing them in a warm, moist forcing-house, syringing them well daily. When the growth for the season is finished, they should be removed to a cooling house, and gradually hardened off, finally treating them in the manner of *Deutzias*. Plants so treated may be forced late the next season, if required.

Solomon's Seal and *Dielytra spectabilis*.—When the flowering is over, these plants should have the protection of a cold frame for a few weeks, and then be planted out in well-prepared beds in April, where, if they are left undisturbed for two years, they will force again. By having successions of these plants, good forcing material may be obtained with a small outlay.

Lilac, *Crataegus*, *Rhododendron*.—Any of these which may have been forced into bloom may, after due hardening, be planted out in the shrubbery, &c., in order to recover which they will do in two years, and again become fit for forcing. Such plants, if large, are invaluable if cut; flowers are much in demand. Double-flowered Plums, Cherries, Almonds, the *Staphylea* are amenable to the same sort of culture as that described above.

The Stove.—As soon as it is remarked that roots show through the moss which is tied round the tongued *Dracenas* and *Crotos*—which, in fact, are layers, the tops should be cut off and potted, using quite small pots, and a light sort of soil at this

potting, viz., one that consists of one-half peat and one-half loam, with a small quantity of decayed leaf-mould and sand to make it more porous. The potted plants should go under a gentle bottom-heat for about ten days, being shaded for that space of time from strong sunshine, and the air about them kept moist. A temperature of 70°, with a rise of 5° by day, will suit them.

General Remarks.—Pots of *Lilium longiflorum* and the variety *Harrisii* may receive a top-dressing of leaf-mould and decayed dry cow-dung, and not allowed to lack water at the roots. Plants of *Freesia* *fracta alba* for flowering in the months of May and June should have the flower-stems supported before they fall over the side of the pots. Introduce large or small batches of them into heat according to the demand. The thorough cleansing and the limewashing of all plant-structures should be undertaken without delay, and roof-blinds of every description put into good order, as they will soon be required.

FRUITS UNDER GLASS.

By F. HARRIS, GARDENER, EASTOOR CASTLE, LEICESTER.

The Fig.—The fruits on the earliest trees will be in most cases ripening fast, and the syringing of the trees will have been discontinued. In favourable weather the colour of the skin and flavour of the fruits will be much improved by affording the house as much ventilation as the weather will permit. In some gardens the fruits of the Fig exude drops of juice all over, which, if not stopped, causes decay. Others are subject to this exudation, and I find that the best preventive is to increase the heat a little, and keep the atmosphere somewhat drier. Liquid-manure may be freely afforded during the last swelling, and till ripening has actually commenced, when clear water only must be used.

Succession Figs.—If the growth of shoots is very strong, the points should be stopped at an early date at the fifth or sixth leaf, reckoning from the base, doing this allowing the shoots full time to form fruit for next year. I much prefer to check Fig-trees at the roots rather than to pinch the points of the shoots; and having tried both methods, I find the former the better one. In thinning the shoots, remove first of all the lateral and weak shoots, by which air and light are more freely admitted to the fruit, giving colour and flavour. If the trees in the late Fig-house are not yet started, no manure should be lost in doing this, commencing at a temperature of 50° by night, and 55° to 60° by day. Let the borders or tubs, as the case may be, receive a copious application of tepid water at starting, and afterwards as often as may be required; and in warm weather syringe the trees twice daily, and damp the paths, walls, &c., several times a day.

Melons.—Plants which are in flower should have the air about them kept a little drier than hitherto, and the female flowers pollinated every day at noon, about which time fresh flowers are expanding, and in suitable condition for setting. When half-a-dozen fruits are seen to be swelling, remove flowers as they form, reduce the number off such to four or five, stopping the fruiting-shoots one leaf beyond the fruit, then, if there is space, permit one or two of the laterals to fill up the trellis, avoiding, however, any crowding together of the growths or foliage. All laterals not bearing fruit should be closely stopped at one joint. Afford slight top-dressings of fine loam mixed with bone-meal occasionally, which is better than richer manure either mixed with the soil or applied as a top-dressing. Keep up a succession of plants by sowing a few seeds in a brisk heat once in ten days, growing the seedlings on a shelf in the Pine-stove or other warm house. If kept near the glass, the plants will be short jointed and sturdy.

THE FLOWER GARDEN.

By CHARLES HERRIS, GARDENER, DROPMORE, MIDDLESEX.

Dahlias.—Roots of *Dahlia* may now be taken from the stove and transferred to a sheltered position outside, and covered with a coating of half-rotten leaves or other light material, and in any case it will be advisable to place these outside or in cold pits or frames before growth commences, as this soon becomes drawn if the roots remain where stored under potting benches. For general use, cuttings taken from old roots answer admirably, and if the latter are of large size, they may be cut up into pieces of two or three shoots each at planting-out

times. If placed outside now, the resulting growth will be short and sturdy, but mats or other covering will have to be used in the event of frosts occurring. Seeds of the single-flowered and Cactus *Dahlia* may be sown at the present time.

Roses.—The pruning of standard and dwarf Roses may now be undertaken, with a reasonable chance of the young shoots escaping from injury by frost. Newly planted Roses should be pruned back to two or three buds, and the rule—an old one—is applicable for H. P. Roses, namely, to prune hard for quality, and the reverse if quantity be wanted. Where not grown for exhibition, many of the strong-growing varieties, grown as dwarfs, may have the best shoots shortened to 2 or 3 feet in length, and then pegged down to the soil, and these will furnish a large number of blossoms. Tea Roses should have the weakest growths cut back closely, and the stronger ones shortened, but not to the same extent as the hybrid perpetuals.

The Rockery.—Any re-arrangement of plants necessary in the rockery should now be carried out. Where trailing plants are encroaching on their neighbours, a portion should be removed. A slight top-dressing of soil may be afforded where spaces allow, and all dead leaves, &c., may now with safety to the plants be cleared away, and the rockery made tidy. *Iris reticulata* has here flowered well planted between large stones; and *Chionodoxa Lucicella* and other bulbous plants are flowering profusely. The *Chionodoxa* is a plant that seeds freely, and seedlings of various shades of colour are appearing in all directions. *Omphalodes verna* is also in bloom, and many other subjects are coming on rapidly.

The Hardy Perenial will require somewhat similar treatment to that detailed above for rock plants. Dead fronds should be cleared away, and a top-dressing of peaty or other light soil placed around the plants.

Various.—The necessary pruning of trees and shrubs should be carried out. This work may often be done when work upon the ground may not be advisable. Laurel hedges require a good deal of cutting to keep them in perfect form, and they are better if cut with a knife, while those made of Holly, Box, and Cypress may be clipped with the shears. In wall buildings may now have the old leaves cut away either with the hedge-shears or a rapping-hook, and be afterwards brushed over with a besom to remove the dirt and rubbish. Lawns should be swept and well rolled before they are mown, and grass verges cut with the edging-iron after having rolled the turf. Tuberous *Begonias* intended for bedding should be placed in pots of a suitable size, and grown on sturdily to the end of May. The potting of bedding *Pelargonium* should now be completed, the plants being kept in shade until somewhat established. If desired, the tops of the shoots may be struck, and they root quickly if placed in heat, and not kept very moist. The propagation of *Heliotropis*, *Josines*, *Messulbryanthemum*, *Coleus*, *Ageratum*, and such like, should be carried on as fast as cuttings can be obtained.

THE KITCHEN GARDEN.

By W. POPE, GARDENER, HIGHLAND CASTLE, NEWJURY.

Globe Artichokes.—The mulching that was used to protect the roots during winter should be removed without delay. The new growths that are beginning to push should be thinned to three or four of the strongest on each. It is good practice to plant a fresh row or two each year, on rich, deeply-worked soil. Strong suckers with a portion of root attached should be used to make these plantations. Plant them in clumps of three, about a foot distant from each other, and 4 or 5 feet between each clump. Plant firmly, and afterwards give a light mulching of short manure or leaf-mould. A good dressing of rich manure should be applied on the old plantation, and then lightly forked in. Where old plants are scarce, seed may now be sown in heat; and if the seedlings be pricked off or potted as soon as they can be handled, and afterwards, when hardened off, are planted in single rows, they will produce heads during the autumn, and the best may be selected for stock.
